diately back by the masses of the chorus, whose clothing forms a quantity of textile material not favourable to the reinforcement and reflection of sound; and individual members of the chorus may find themselves close up against instruments playing something different from what they are singing, which cannot conduce to steadiness in their parts. I propose to place band and chorus on two different stages, as shown in the section, Fig. 3, the band being backed by a wooden sounding-board carried up behind the back row of players and slightly curved forwards, so as to act as a reflector and strengthener of the sound. The chorus, on the seats above, would hear the band quite sufficiently, but *en masse*, and not with some of the instruments almost mixed with their own ranks. Then there comes the question of the organ. Generally speaking, insufficient area and height are left for the organ, and either it is bracketed out over the heads of the chorus, which puts it right against the ceiling (a bad position for its effect) or it is projected out into the chorus seats, which puts the singers on each side of it into a recess where they cannot hear each other; and though the singers are supposed to be all governed by the conductor, it is more conducive to keeping time and tune that they should be able to hear each other. The organ in my scheme forms the background to the whole orchestra, but it is not necessary that its real height should start from the top level of the chorus seats. The pipes placed in front must do so—the wind is conveyed to them through conduits; but the wind-chest on which the bulk of the pipes stand could be placed a good deal lower, and that for the large pedal pipes (on the right hand of the section) lower still; they will be just as well heard, and there is then no need for making special provisions for their height above the ceiling of the orchestra. There should be a solid wall behind the organ, and no windows in it, to keep it as much as possible from changes of outside temperature. And as we can now have electric action between the keyboard and the organ, the keyboard should be placed at A, in front of the band and chorus, so that the organist can know what effect he is producing, which he cannot know if he is seated close up to or almost in the organ. I have heard an organist, in that position, drown the whole band and chorus with the sounds of a large organ, probably without being the least aware that he was doing so.

I have often thought that it would be rather a fine thing to have a kind of combined concert-hall, as shown in Fig. 4, with a large hall for band and choral performances, a small circular one for instrumental chamber music, with the platform in the middle, and another small circular one for vocal chamber music, with the platform at one side. It would be capable, as you will see, of being made an effective architectural group. The large hall in this plan will seat 1,800, on a floor rising from front to back, without any galleries; but a cross gallery might be formed over the back portion of it.

The increasing size of our cathedral organs is leading to difficulties as to the placing of the organ. The old position of the cathedral organ on the choir screen was admirable both for musical and architectural effect; I know it has

FIG. 4.—PLAN FOR COMBINED CONCERT-HALL FOR THREE CLASSES OF CONCERT

been objected that it interfered with the vista, but to my mind the old cathedral organ on the screen, sometimes with a beautifully designed case, was a very fine object and an addition to the architectural effect. The reason for the increased size of the modern cathedral organ is that we have now learned from the example of Germany that the pedal organ ought to have a complete set of stops—ten or twelve, instead of having only two stops to make a booming effect, and couple the pedal to the manual for the rest of the stops; and it is the pedal pipes that make the size, as they are all twice as large as the corresponding pipes in the manual part of the organ. Hence the organ gets too large for its old position on the choir screen. To put it in the transept is perhaps the best, for the organ effect, but it gets rather too far from the singers that way; to put it in the triforium, as has been done in one of the cathedrals, is one of the worst ways; it is all boxed up there, and cannot be properly heard. I think the difficulty might be met by building up the organ from the floor, under one of the crossing arches, but turning it round, so to speak, so that its longer axis was on the longer axis of the building. It would be possible in that way to build a large organ and yet leave room at each side for an archway into the choir.

The position of the organ in the parish church is hampered by the custom of placing the choir on each side of a long chancel, and to get the organ near them it is put in an "organ chamber," where its sounds are quite smothered. The best place for the organ itself is in a west-end gallery, but in a large church that puts it too far from the singers; in a small church it has been done satisfactorily. For a large church, if you must have the singers in the long chancel, a counsel of perfection would be to have a small organ close to them to accompany them, and a large organ in the west gallery to accompany congregational singing, played by electric action from the keyboard in the chancel; but it is of course a costly method. The whole difficulty arises from the notion that the choir must be seated in a long chancel, which is only a survival from the fact that the mediæval services used to be sung by the monks in the choir. The modern choristers are not clerics; they are simply singers, either voluntary or hired, and the long chancel is the worst position for them either to lead the congregation or to be heard by the latter. Their position in the long chancel is a mere piece of tradition. I suggest that we should go back to an older tradition, and that the Latin basilica church is the best form for modern worship. In the upper plan in Fig. 5 the choir are placed in the space which used to be called the *bema*, between the arcade and the east wall—a kind of shallow transept, and the organ in one or both of the spaces behind them. That is not an ideal place for it, but it is at all events better than the organ-chamber; and the choir would be much better heard there than in the long chancel. A still better way, for practical purposes, is to have the organ in a west gallery, above the

narthex shown in the lower plan (which we will suppose to be a church in the Gothic style), and the choir half-way down the nave on each side. They could then be well heard by the congregation, and be not too far from the west end organ. This plan has been adopted in Lincoln's Inn Chapel, with satisfactory results.

The organ-case is capable of being made a splendid architectural feature, and its possibilities in that way are too much neglected at present, mainly from motives of economy. It may be treated on two principles; either as a decorative open-work screen, concealing the pipes entirely; or as an erection in which the larger pipes are mounted in front as part of the design. To do this the pipes in front have to be taken away from their proper position on the wind-chest, and the wind conveyed to them through special conduits; this is a slight disadvantage and expense, but the appearance of the large pipes in front is so fine in a decorative sense, and so symbolic of the meaning of the erection, that it is worth while to have them as part of the design. When so used, the principal towers of pipes should be on the flanks of the design, not in the centre, as that is the way they are arranged on the wind-chest—the large ones at each end, the small ones in the middle, in order to equalise as much as possible the demand for wind. One of the finest organ-cases in England is that designed by Cockerell for St. George's Hall, Liverpool, though its effect is very much spoiled now by the subsequent erection of the wooden orchestra seats in front, which hide the lower part of the case; for it is another of the little jokes about St. George's Hall that, though it was supposed to be built for musical performances, no one ever thought of designing an orchestra; Cockerell, who completed the interior after Elmes's death, merely introduced a small semicircular tribune on columns in front of the organ, which of course was of no practical use except for solo-singers. One of the fine points in Cockerell's design for the case was that he utilised some of the great square wooden pipes (generally overlooked in designs), placing them effectively in a semicircle round the back of the organ. Among celebrated organ-cases that at Saragossa cathedral is a very fine example of what may be called the romantic style; rich perforated work in a late Renaissance style, influenced no doubt by the recollection and example of Moorish decoration. In this case everything is flat, the effect being got by richness of perforated decoration. In the magnificent Renaissance organ case at Haarlem everything, on the contrary, is modelled; the effect is got by outline and modelled surfaces, in a more directly architectural spirit. In this and other German organ-cases the fine effect should be noticed of the placing of the light choir organ (what the Germans call the *positiv*) as a separate small organ in front of the large one; this not only makes an effective incident in the design, but assists the sense of scale. There is a grand Renaissance organ-case in the cathedral at Troyes, to which my attention was drawn by finding it made the subject of a fine picture in last year's Paris Salon—"Le Grand Orgue à Vepres," by M. Henri Magne; the only time I remember to have seen a large organ made the subject of an important oil-painting.

It is scarcely necessary to say to an assembly of architects that the concert-room ought not only to be a good music-room, but a good example of architectural design. Unhappily this is not often the case, for in this country theatres and concert halls seem scarcely ever to be commissioned to eminent architects; there are evidently other motives for such appointments which one cannot well fathom. They are nearly always started as commercial speculations, and I have seen it stated that an architect is selected, sometimes at all events, because he is willing to take up shares in the concern. To those who may have the good fortune to be commissioned to carry out a concert-hall for better reasons than that, I would say—try to get rid of the prevalent idea that buildings for any kind of entertainment must always be florid and bedizened with gilding in their interiors. That may be suitable for the "music-hall" type of entertainment; but a building which is to be the home of classical music should surely aim at representing the most dignified and refined type of architecture and decoration.

FIG. 5.—POSITION OF CHOIR IN CHURCHES.

L.C.C. CORONER'S COURT, POPLAR.]

The court buildings, in High Street, Poplar, provided by the London County Council, were designed with a view to convenient use with the mortuary buildings adjoining them, which were erected by the Metropolitan Borough of Poplar from designs approved by the Council.

The accommodation includes the court room, coroner's room, a waiting-room for female witnesses with a lavatory adjoining it; a hall with waiting space for male witnesses, and lavatories for the coroner and the jurors.

The court room is oak-panelled, and has an open timbered roof, with tie beams and principals of English oak, ceiled at collar level. It is arranged so that the witnesses' box, which is movable, is near to the door of the court. On the dais, to the right and left of the coroner's seat, are two other doors, one for the jury, and the other for the coroner, both opening into a corridor connected to the mortuary by a covered way. A private entrance from the street is provided for the coroner, and another for the caretaker, whose quarters are on the first and second floors, and have four rooms and a bath-room and a scullery with a copper and gas stove.

The walling generally is of brick, faced with hand-made sand-faced red bricks from Hampshire, and the red roof tiles are from the same field as the bricks. The dressings are of Douling stone.

The floors of the public rooms are laid with pitchpine blocks. The warming of the court is by low-pressure hot water, and ventilation is obtained by fresh-air inlets behind the radiators; in the ceiling are gratings for the outlet of foul air.

Messrs. Gathercole Bros., of Norbury, were the contractors, and Mr. W. E. Riley, F.R.I.B.A., the superintending architect of the London County Council, was the architect.

DEFECTS AFTER COMPLETION.

BY A LEGAL CONTRIBUTOR.

A correspondent has drawn our attention to a passage in Mr. Henry White's paper on "The Legal Liabilities of an Architect," read at a recent meeting of the Royal Institute of British Architects. The passage in question, as it appears in our necessarily condensed report on December 27th, is as follows:—"It

does not seem to have been generally realised among members of the profession that the architect's position to his client is a most invidious one as regards liability. The builder, after the usual twelve months' maintenance clause has expired, is freed from all further responsibility towards his client, but the architect remains liable up to the period allowed by the Statute of Limitations—i.e., six years. This is a ridiculous position!"

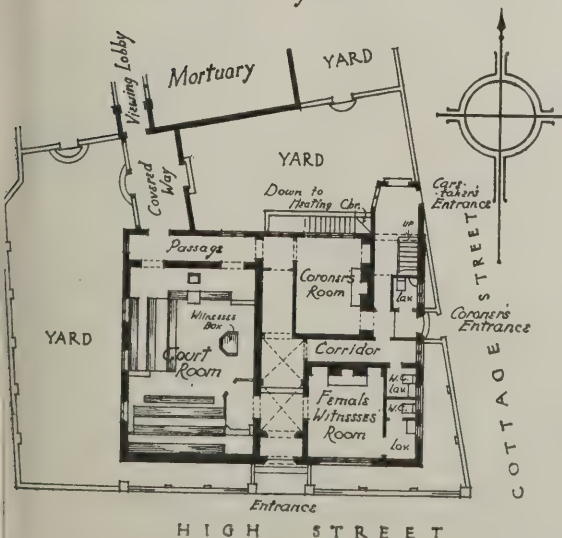

Our correspondent compares with this a statement made by Mr. Greenop in the paper read by him at the same meeting. Mr. Greenop is reported as having said, referring to the case of *Leicester Guardians v. Trollope*: "It is interesting to note that the judge expressed the opinion that the clients were in error in supposing that, as two years had elapsed since the date of the final certificate, they were debarred from proceeding against the builder." Our correspondent adds, "It would be interesting to have your opinion on this important matter, as there ought to be no question as to whether a builder could or could not be held responsible in a case of this sort." We have submitted the matter to our legal contributor, who writes as follows:—

In considering the results of decided cases, it is always necessary to bear in mind that each decision depends upon its own facts; and the causes in the particular case before the court have a most important bearing upon the result. In the absence of a special provision in the contract, the position of the builder and the architect is precisely the same. Each is liable for negligence or breach of contract up to the end of the full period allowed by the Statute of Limitations.

It is important to remember, in the first place, that the use or occupation of a building which has been partially erected, even though for the purpose for which it was intended, is not an acceptance of the work or any part thereof, nor a waiver of defects so as to preclude the employer from objecting that the contract had not been fully performed.

L.C.C. CORONER'S COURT . .

HIGH ST POPLAR E.

• Ground Floor Plan •

• Second Floor Plan •

• First Floor Plan •

L.C.C. CORONER'S COURT, POPLAR:
FIREPLACE IN CORONER'S ROOM.

In one case the plaintiff, a shipowner, bought copper sheathing of the defendant, a copper manufacturer, and the copper was put on the ship, which sailed; but the copper, instead of lasting from four to five years, as usual, became corroded in four or five months, and became unfit. It was held that the plaintiff could recover damages, notwithstanding the acceptance (*Jones v. Bright*, 1829. 5, Bing, 533).

Further payment of, or judgment for, the contract price is no bar to claim by the employer for defective work, nor for damages arising out of the breach. (*Davis v. Hedges* (1871) L.R.6.Q.B.687).

It is material to notice, however, that where work is agreed to be done to the approval of the building owner or his architects, the expression of that approval will prevent any recovery by him for patent defects subsequently discovered. So where a builder contracted to do certain work to the satisfaction of the building owner and his architect, the contract provided that if the use of improper materials or non-performance of the contract appeared within twelve months after completion, the building owner should be entitled to bring suit against the builder, any certificate of the architect notwithstanding. The works were completed, and the architect granted his final certificate, and the building owner impliedly expressed his satisfaction, and paid. More than twelve months afterwards it appeared that bad materials and workmanship had been employed, yet it was held that the building owner had no claim against the builder.

Where the contract is silent in the matter, the measure of damages for incomplete or defective performance is what it would cost to rectify the defects or omissions at the date when they might have been discovered, or when the particular part of the work was completed. And the measure of damage for non-completion to time will include any loss occasioned by the failure to complete the building for its intended use within the contract time, if the particular use can reasonably be supposed to have been in the contemplation of the parties when the contract was entered into, with an

additional sum for loss of use of premises during the repairs.

Apart from the terms of the contract, it is manifest that the contractor could not by any possibility be held responsible for defects arising in the course of time from wear and tear. But if there is a structural defect which ought to have been detected and put right when the works were in hand, it is conceived that the contractor remains liable, for the time at which the defects become apparent has a material bearing upon the question of liability. Thus a breakdown ten years after completion may be due to ordinary wear and tear; while if the same mishap were to occur within a month of the contractor's handing over the work as complete, it would require strong evidence to show that he was not at fault. It is impossible to lay down a general rule by which the liability of the contractor can be ascertained. The time, the nature of the defect, etc., are matters for the consideration of the court.

The following points have been clearly decided: (1) that mere acceptance of the works by the employer is no answer to a claim by the employer in respect of defective work; and (2) if there is a settlement between employer and contractor, it is a question of fact whether that settlement is intended to cover future as well as past claims for damages.

Circumstances may arise, however, in which the certificate of an architect may prevent the employer's making a claim for defects.

CORRESPONDENCE.

Cheap Cottages.

To the Editor of THE ARCHITECTS AND BUILDERS' JOURNAL.

SIR,—With reference to your leading article on p. 289 of your issue of March 20th, I should like to mention another direction in which the cost of cottage building could be very materially reduced. We saw in above-mentioned article how economies could be effected through the materials employed. Another well-known expedient is to economise in the size (or accommodation) of the cottage. The third, and, to me, most obvious expedient, does not appear to have been given much thought. The cost of a cottage (as we know) is made up of materials and labour, the latter being the larger portion, and it is in this direction that I propose economising. Let me say now definitely that I do not mean that men should be underpaid or sweated, etc.

In country districts numbers of the people can turn their hands to almost any form of local employment and change from one to the other with perfect ease—farming or brickmaking, thatching and tiling, road-making, builder's labourer, well sinking, etc., etc. In country districts, also, people are often out of employment for a few weeks. Now my point is, that in country districts where cottages are scarce they could be built by the men themselves in the slack time, the parish council providing the land and the materials.

L.C.C. CORONER'S COURT, HIGH STREET, POPLAR: THE COURT ROOM.
W. E. RILEY, F.R.I.B.A., SUPERINTENDING ARCHITECT.

The rent would be based on the sum spent by the council on the cottages, and would work out at about half the usual cost of similar cottages. The men would be reimbursed for their work by having to pay only half the usual rent. The money value of their services would thus be repaid in 2 or 3 years! The cottages would be secured against the rents being raised; and the tenants would be also secured against dismissal, so long as they did not let the property down; the property being vested with trustees.

Supposing a block of 4 or 6 cottages were built, that would represent 4 or 6 men (heads of houses) and probably there would be sons in addition. (Possibly some of the womenfolk would assist—they are fond of outdoor work.) As to skilled work, like joinery—the doors and windows and dressers, etc., can be bought ready-made, and fireplaces would be bought ready put together—and so on. Of course, the work would be properly supervised. The men would take an interest in the work, and be less likely to skimp than otherwise.

Working on these lines—making labour restore the balance, and tapping the vast resources of latent wealth shut up in unemployment—there is no need to stint the size of the cottage. There can be a front parlour as well as a living-room; and three decent-sized bedrooms upstairs—not the cupboards usually found in cheap cottages. The materials, too, would be good, and consequently the subsequent repairs would be much reduced. Again, with security of tenure there would be inducement to a tenant to make improvements and additions, etc., both externally and internally.

To sum up, suppose the cost of materials, etc., came to £100 per cottage: that, at 5 per cent. (which would probably be sufficient interest) represents a rental of £5 per year—say 2s. per week. This would be quite as low as would be required for any district. In the neighbourhood in which I am living, the demand is for cottages at 2s. to 2s. 6d. per week. Of course, discretion would be used as to tenants, and well-paid men would not be allowed to take them, as they could afford more expensive cottages; and, on the other hand, undesirables would be excluded, and anyone who let the property down would be given notice to quit.

In conclusion, I may remark that the scheme is by no means new really, as a few generations ago, it was just what people did! They built their own houses—of "wattle and daub," perhaps—but the point is, they *built* their own homes, and of local materials, many of which houses remain now, at rents within the limits of the agricultural labourer's means. Present-day cottages would be built, of course, of more substantial materials, but they should be built by the people. It was the natural thing to do in days gone by, and we can take it to be the natural solution of the problem to-day. People have got so accustomed to having everything done for them nowadays that, like hermit crabs, they now can only live in houses built by other people.

To mention some existing instances of this scheme, Roman Catholic brotherhoods, etc., I believe put up their own buildings; work their own land; carry on trades, etc., on this system (namely, doing it themselves), and are in a position to undercut any tradesman, nurseryman, or builder, and even schools, in the country. I do not see why the cry of expense of cottage building should not

L.C.C. CORONER'S COURT, HIGH STREET, POPLAR: ENTRANCE HALL AND CORRIDOR. W. E. RILEY, F.R.I.B.A., SUPERINTENDING ARCHITECT.

be knocked on the head by the same means (it would only be a modern form of the old-time crafts really).

This scheme I now humbly put forward, in the hope that it may provide an idea or two in seeking the solution of this widespread problem of housing reform, and apologising for trespassing so unconscionably on your valuable space.

LICENTIA TE R.I.B.A.

[We cannot suppose that our correspondent's proposal will find much support among those who are regularly engaged in the building trade; and we should unhesitatingly agree with them that in every case building should be done by builders. We have withheld our correspondent's name in order that he may not suffer from the full force of the avalanche which his purely altruistic proposal seems pretty certain to bring down upon his devoted head.—EDS. A. and B. J.]

The Coal Strike and Time Clauses in Contracts.

To the Editor of THE ARCHITECTS' AND BUILDERS' JOURNAL.

SIR,—The unparalleled confusion in industry brought about by the coal strike leads us to point out two pieces of practical patriotism, which, if generally followed at once and for the immediate future, would do much to mitigate the after effects of this disaster. As a firm employing thousands of men we view with anxiety the inability of railway

companies to transport our stone and granite products from the quarries, many of them inland, to their destinations. All railway companies have issued notices involving the total cessation of such traffic till the conclusion of the strike. This places us at a disadvantage with foreign competitors, who, in foreign vessels with foreign coal, can ship to a British port giving the shortest possible land journey to site, and can supply materials for the completion of contracts for which, through no fault of our own, our materials are not at present available.

As this difficulty is shared, we believe, by a large number of British firms supplying all sorts of building and engineering materials, we venture to urge on all architects, surveyors, engineers, and builders that as far as possible, except in the case of absolutely necessarily urgent work, an agreement be made to waive the time-clauses of contracts as far as is reasonably possible in order to preserve as much work as possible for British firms and British workmen when the crisis is over.

The abnormal conditions also variant us, we believe, in urging that during the period of depression which must follow the present crisis, the Government Departments, also public bodies such as municipal corporations, as well as architects, surveyors, and engineers stipulate that, so far as possible, British materials only be used in work under their control until normal trade is again obtained. A

system of voluntary patriotic action of this nature is, we believe, sure to find favour at the present time among responsible persons of every shade of political thought, and we therefore venture to make these two suggestions.

UNITED STONE FIRMS, LTD.

2, Bristol Chambers, Nicholas Street,
Bristol.

Associates and R.I.B.A.

To the Editor of THE ARCHITECTS AND
BUILDERS' JOURNAL.

SIR,—Your editorial on this subject was a weighty warning to the Institute and others as to the possibility of Registration.

I my opinion, we shall never get it, because there is no public need for it—our own needs are another matter. The public are safeguarded by by-laws and officials, and it is their purse mostly that is in the balance.

The Institute have thrown open the doors to all sorts and conditions of Fellow and Licentiate, and for what use—what goal?

To the public these letters make no difference or, if any, possibly, on the side of the Licentiate.

In my opinion the Institute was getting stronger and stronger, without any door opening.

The Royal Academy and the R.I.B.A. were quite enough gradually to force all to become properly qualified.

I hope associates will try and get the Institute back to its old position, as Registration is not practicable. Ask any lawyer!

London, E.C. ASSOCIATE.

WARMING AND VENTILATING SPECIALITIES.

Messrs. E. H. Shorland and Brother, Ltd., of Failsworth, Manchester, forward for notice a copy of their new catalogue, No. 30, just published, showing their warm-air ventilating patent Manchester grates, patent Manchester stoves with open fires, patent exhaust roof, and special inlet ventilators. The catalogue is divided into three sections, to facilitate easy reference, the patent Manchester grates being listed on white paper at the front of the catalogue, the patent exhaust roof and inlet ventilators being on red paper in the mid-distance, and the patent Manchester stoves on blue paper at the end. A few words of introduction are given at the commencement of each of the three sections. There are also several coloured illustrations of patent Manchester grates and stoves.

The first series of Manchester grates illustrated are those with the firm's latest patent low fire projecting back. These grates having no bars to interfere with the radiating properties of the fire, better results are consequently attained with this latest form of Manchester grates; but as there are many persons who prefer grates with bars, grates of this type fitted with an improved projecting back are listed. The catalogue contains a list of some of the buildings to which the patent Manchester grates, stoves, or ventilators have been supplied, and views of a few of these buildings are included.

The patent exhaust roof and inlet ventilators are all made by special machinery.

The patent Manchester stoves are now fitted with the firm's latest patent warm-air-mixing chamber, which greatly increases the heating capacity of the stove, without any additional consumption of

fuel. These stoves are made either single or double-fronted, and with ascending or descending smoke flues, thus allowing the stove to be fixed in the most desirable position. The stoves are supplied in a variety of designs and finishes, from the most elaborate stoves encased in richly glazed faience of any colour, down to the plainer patterns of cast iron; but the internal construction is the same irrespective of the design and finish.

Where ascending smoke flues are used these are encased in either richly glazed faience or with iron outer casing, with outlet near ceiling level for the extraction of the vitiated air, thus forming a combined powerful warming and extract ventilating system. Nearly all the hospitals erected in recent years have in use Shorland's patent open fireplace Manchester stoves.

ELECTRICAL SUPPLIES.

A new edition of Sections T, D, U, and M of the catalogue of Messrs. Simplex Conduits, Ltd., wholesale electrical suppliers and manufacturers, 116, Charing Cross Road, W.C., and Garrison Lane, Birmingham, which has just been issued, covers all prices and particulars of the Simplex Steel Conduit System, together with the products of the Simplex Company's switchboard and fuse department; as well as reflectors and fittings designed for mill and factory lighting. In the present edition of the catalogue the latter lines in particular have been considerably extended. Section T comprises conduits and fittings; D, distribution boards, switch gear, enclosed fuses; U, the Simplex flexible wiring system; and M, water-tight fittings for mills, ships, etc.

The general arrangement of the list is based upon the firm's fifteen years' experience of conduit manufacturing, and arranged with a view to giving clearness and facility for reference.

In regard to the various additions to the Simplex Steel Conduit System, attention may be drawn to the Simplex Universal conduit box, which is designed with the object of providing one fitting which will fulfil all the various purposes which are met with in the average conduit installation; that is to say, the box may be used as a junction box pure and simple; as a ceiling rose box, switch box, pendant box, or plug box. It is listed complete in all these various combinations in the catalogue, and it is suitable for use with one, two, three, or four runs of conduit. It is often a matter of difficulty to specify accurately what the requirements will be on any one job; and, in order to save duplication in their stocks, contractors can obtain these boxes ready drilled and tapped, but with each outlet stopped by means of a small screwed plug. Thus, if on an installation a contractor is likely to require both one-way and two-way boxes, he can at a small extra charge have all the boxes ordered two-way, with each outlet stopped by one of these screwed plugs. To utilise the box either as a one-way or a two-way, it is only necessary to remove one or both, as the case may be, of the plugs by means of a screw-driver.

Another section of the list which has undergone considerable extension and revision is that relating to tools. Several pages are now devoted to the illustration and pricing of various wiremen's tools, such as are required in every-day installation work. These comprise—in addition to such essentials as screwing tackle—speed counters, micrometer gauges, port-

able tube vices, etc. The improved pattern portable tube vice, for screwing or cutting tube, is recommended as being very handy for large conduit jobs. It has a combined pipe vice (up to 2 in.), with ordinary parallel jaws, and is fitted with a convenient shelf for tools.

The fuse section has been added to by the inclusion of particulars of Hope's bi-metal fuse wire, the 5-amp. and 10-amp. sizes of which are now ready for delivery.

The section dealing with reflectors, etc. for factory lighting, has been extended by the inclusion of pressed steel reflectors designed on scientific lines, manufactured under the Holophane-Benjamin patents.

A CENTRAL HEATING AND POWER PLANT.*

By R. J. DURLEY B.Sc., MA.E. M.Inst.C.E.

Economic and other conditions have led in many places to the development of central plants for the distribution of heat to large groups of buildings or to districts in towns, and these installations are in successful operation both with and without accompanying electric generating-stations.

The present paper describes the arrangement and equipment of a central heating-plant, combined with an electric-light and power station, designed to serve the various buildings of McGill University. Although only of moderate size, the installation is of interest on account of the somewhat severe climatic conditions and the unusual nature of the service. Attention is called to the fact that the economic possibilities of such a station depend very largely on the relation between the demand for heat and that for electric current.

The University buildings were, up to 1908, heated individually by their own steam or hot-water equipment, and took current from the local electric-supply company. The coal used for the heating service was necessarily of an expensive kind, and the cost of current was rather high. Economy and improvement in service, therefore, were sought by utilising cheaper coal in a central boiler-plant, and heating the various buildings from one source, employing for this purpose as far as possible the exhaust steam from electric generating-sets. The buildings which will ultimately be served have a total volume of about 7,570,000 cubic feet; they contain 81,000 square feet of direct-radiation heating-surface, need 185,000 cubic feet of warmed air per minute for ventilation, and require as a maximum about 475 kilowatts for light and power. The greatest demand for steam for heating and ventilation for all the buildings in cold weather would be about 30,000 lb. per hour.

The station as at present working supplies current to eleven buildings, and heat to five; and the heating service will be extended to all the buildings as opportunity serves.

A brief discussion of the systems of heating and ventilation in general use in Canada for large buildings, and a description of the nature of the demand for steam and current for the University purposes, is followed by notes as to some of the problems arising in the design and construction of underground piping systems for steam and hot water.

The McGill power-house itself is not of an unusual type, its equipment including four water-tube boilers, three

*Abstract of a paper read before the Institution of Civil Engineers.

steam-electric generating-sets, the necessary heaters and auxiliary machinery, and the ordinary apparatus for the switch-board and electric accessories.

The heat-distribution to the buildings being largely by means of forced circulation hot water, as well as by steam, the heaters and circulating-pumps are installed in the engine room, and are at present capable of supplying hot water to 60,000 square feet of direct-radiation heating-surface. Means are provided for obtaining a record of the heat delivered to the heating systems of the various buildings.

The electric distribution is by underground cables throughout, the cables as well as the heat-distributing pipes being carried partly in tunnel and partly in conduit. Secondary heaters have been installed in two of the buildings, in order to avoid the expense of renewing their existing heating-pipes and radiators.

The paper closes with a description of the methods of operation adopted, and the systems of temperature regulation employed, together with some notes as to working-costs.

SOCIETY OF ARCHITECTS.

The fifth ordinary meeting of the Society of Architects for the Session 1911-12 was held at 28, Bedford Square, W.C., on March 7th, at 8 p.m. Mr. Percy B. Tubbs, F.R.I.B.A., (vice-president) in the chair.

Three nominations for membership and ten for studentship were announced.

The ballot was taken, and the following candidates were declared to be duly elected as members:—Brown, E. O., Gravesend; Chasemore, A. E., London, S.W.; Fincher, P. R., Neath; Kemp, W. J., junr., London, N.; Miller, J. M., Montreal. Fifteen students were also elected.

Mr. A. Alban H. Scott (member of Council) then read a paper on "The Testing of Materials for Reinforced Concrete," an abstract of which appears in another portion of the present issue.

THE LONDON ASSOCIATION OF MASTER DECORATORS.

A meeting of the general committee of this association was held at the offices, 92, Queen Victoria Street, E.C., on March 11th, Mr. C. E. Wilkinson in the chair.

The Secretary read letters received from the Employers' Parliamentary Council, the Prime Minister, and the Trades Disputes Act Reform League, and presented a copy of the proposed Bill for the amendment of the Trades Disputes Act. He explained that he had written to the Prime Minister, submitting that a deputation should be allowed to wait upon him, and the letter in reply to that request was read. The Prime Minister regretted his inability to receive a deputation.

The Chairman said that the only thing the association could do was to support the Bill, using what influence it had with Parliamentary representatives. He thought the Bill had the unanimous support of the members.

It was agreed that the secretary be instructed to write to the Master Builders' Association, saying that the members present at the committee meeting that evening had signed the petition, and cor-

dially endorsed the action they were taking in the matter, and sent another resolution to Lord Claude Hamilton, informing him that the matter had been discussed by the committee, which was unanimously in favour of the Bill he was promoting.

A letter from the London County Council on the subject of technical education was referred to a sub-committee for consideration and report.

The Secretary read a letter from the National Federation of Building Trades Employers with reference to the question of merchants supplying goods direct to the public on trade terms. The association was asked what they were doing in the matter, and in what way the Federation could help the association or the association help them.

The Chairman thought the reply might be that the association were taking the matter up whenever they received information, and had been successful in dealing with the firms.

It was agreed to place on the agenda, for discussion at the next meeting, a proposition as to means of helpful intercourse with the Paint and Varnish Society.

It was agreed that the Insurance Act, as it affected members of the association,

should be set down for discussion at the next quarterly meeting.

The Secretary submitted proof certificates, samples, and estimates of costs in connection with the proposed Continuous Certificate of Discharge, and it was agreed that as soon as the card had been decided upon the secretary should be instructed to write to a number of firms asking them to take the matter up, and saying the cards could be supplied at such-and-such a price, and also that if taken up, it would be in the interests of themselves and of the men.

Messrs. C. Collier and Son, of 4, New Quebec Street, were elected members of the association.

Civil Engineers' Examinations.

Excellent results have recently been obtained in the examinations of the Institute of Civil Engineers by Messrs. Penningtons, University and Engineering Tutors, Oxford Road, Manchester. Associate Members' Examination: Messrs. G. Le Huquet, R. B. Dorman, F. A. Watson, J. Wilson, Butler, E. H. Pike, J. S. A. Walker, P. Holt, F. A. Davies, E. Jones, G. Stewart, L. Tod. Students' Examination: Messrs. R. G. Torrens, J. T. Thompson. There were no failures.

CHIMNEY-STACK ON HOUSE AT WITLEY, SURREY. E. L. LUTYENS, F.R.I.B.A. ARCHITECT.

NEWS ITEMS.

Liverpool Architectural Society.

The Council of this Society requests all members to refrain from competing in the following architectural competitions—Warrington Schools; Llandudno Police Buildings; Ormskirk Golf Club.

Marriage of Mr. Rudolf Dircks's Daughter.

The marriage took place at Heyshott, near Midhurst, Sussex, on March 16th, of Mr. Richard Cobden-Sanderson, son of Mr. and Mrs. Cobden-Sanderson, and only grandson of Richard Cobden, and Miss Dorothea Dircks, daughter of Mr. Rudolf Dircks, Librarian of the Royal Institute of British Architects.

Models of Old London.

The five models of Old London made by Mr. John B. Thorp, of the London Drawing and Tracing Office, 98, Gray's Inn Road, W.C., which were exhibited at the Franco-British Exhibition and afterwards at the Festival of Empire, have been acquired for the London Museum, where they are shown in an annexe specially built to receive them.

Ecclesiastical Metalwork.

There is now on view and for sale at the London depot of the Duchess of Sutherland's Cripples' Guild, Ltd., 14, New Bond Street, W., a collection of ecclesiastical metalwork executed by crippled lads—some of it from old models and some from designs by architects, including Mr. Temple Moore, F.S.A. The collection is certainly worth a visit.

Strasbourg Cathedral Tower.

The tower, 142 metres high, of Strasbourg Cathedral rests on foundations that are nearly 650 years old, and have evidently become unsound, since for some five years past the doorway has shown cracks which are continually widening. The remedy that has been decided upon by an international commission of architects is rather surprising. The tower is to rest on a platform constructed of oak-tree trunks "capable of supporting the eight millions of kilos which it weighs." The cost is estimated at more than £6,000.

Sulphur and Reinforced Concrete.

When reading analyses of clinker for aggregate in reinforced concrete, the rule—Cast aside sulphite; but sulphate is first rate—is easy to remember and always to be relied on. Of the three chemical unions of sulphur, the first, sulphide, is a compound of sulphur and a metal; the next, sulphite, is a compound of sulphur, a metal, and a little oxygen; and the third, sulphate, is sulphur, a metal, and more oxygen. The sulphur in the sulphate has absorbed all the oxygen that it chemically can absorb or unite with, and further chemical action is therefore impossible.

Collapse of an Old Roman Wall.

A large portion of the south or Port Wall of the Roman city of Venta Silurum (Caerwent) has collapsed. The exploration of the city has occupied considerable attention on the part of the Clifton (Bristol) Antiquarian Club, and many other archaeologists. The wall was one of the finest of its kind in the Kingdom. The north side of the wall, which is over 20 ft. high, is filled up with soil to within a few feet of the top, while the south side is free from top to bottom.

The expansion of the soil inside, caused by the recent change to a higher temperature, caused the southern, unprotected face of the wall to fall outwards, leaving the core and the northern face still standing. Steps were about to be taken to support another portion of the wall, but no measure to strengthen the part that has fallen was deemed necessary. The rubble or herring-bone masonry has been exposed, and it is thought probable that this also may soon collapse.

Lectures on Town Planning.

A course of lectures on town planning will be commenced at the offices of the Garden Cities and Town Planning Association, 3, Gray's Inn Place, W.C., on April 12th next, and will continue every Friday until Whitsuntide. The first lecture will be given by Mr. Raymond Unwin, F.R.I.B.A. The lectures will be open to all who are interested in the subject, and opportunities for questions and discussion will be afforded. Tickets for the course may be obtained from the secretary of the Association, Mr. Ewart G. Culpin.

The Architecture of Stamford.

With reference to the article under this title which appeared in our issue of October 4th, 1911, the Mayor of Stamford has, at the hands of Mr. Henry Walker, of the Stamford Public Library, kindly forwarded some interesting notes and corrigenda; the most important of which are—that "Erving Road" should read "Ermine Street"; that the Crown Inn has now been rebuilt; that "The Portico," shown on p. 355, has been transformed into the public library; and that 41, High Street has been altered for the accommodation of the co-operative stores by which it is now occupied.

The New London University.

Now that sums amounting to more than £300,000 have been promised towards the acquisition of the vacant site on the Duke of Bedford's estate north of the British Museum, it seems likely that we shall eventually see erected there a building worthy of a great University.

OUR PLATE.

The Secluded City of Ecalpon.

One can only 'approach Ecalpon by night, and, as all who sleep in the city are mysteriously spirited away and awake only to find themselves in some quite different place, the buildings and tortuous streets of the quaint little town have not often been described by travellers or guide-book compilers.

But, apparently, the cathedral was begun by a Laon mason and enlarged by one who had seen Beauvais and Rouen. And the latter-day ecclesiasties grew lazy and built themselves snug lodgings, leaving their church to be perfunctorily finished off in the Renaissance period.

The town church, too, is a queer, unfinished jumble of Flamboyant and Renaissance work, and there is an old castle overlooking the river, while artists with an affection for such things may sketch the Louis XVI. Hotel de Ville, which appears in the background of the illustration.

The exact locality of the city is a secret. Its name if spelt backwards may supply a hint of its whereabouts.

CHARLES A. NICHOLSON.

NEW ICE RINK, EDINBURGH.

The new ice rink, Haymarket, Edinburgh, which was recently opened, has been constructed upon the site formerly occupied by Swan's cattle mart. The building, which is placed east and west on the site, has an internal length of 220 ft. with a breadth of 120 ft., and a height to the roof, which forms an elliptical arch, of 38 ft. The ceiling is of plaster, and is divided by bold bands into seven bays, in the centre of each of which is a ventilator grille. Three rows of five-light electrolights depend from the ceiling, the whole building being lighted by means of electricity. Daylight is admitted by a row of semicircular clerestory windows on the north and south sides of the hall and by three large circular-headed windows in the east gable. The glass of the windows is of a special kind, made in such a manner as to throw the whole of the sun-rays upon the roof and not on the floor of the rink. In the west gable is a large structural arch, with recess, and on each side of this arch, and on each side of the east windows, the wall space of the gables is covered with large pictures executed by the scenic artist, Mr. F. T. Dunn, of the Theatre Royal, illustrative of the seasons. The ice surface will have an extent of 17,000 square feet, forming, it is said, the largest ice rink in the kingdom. This large area is entirely free from pillars of any kind. At the east end of the hall are tea and dining rooms, kitchen, cloak-rooms, repositories for skates, etc.; at the west end are rooms for the storage of curling stones, and in front of the arch already referred to are an elevated bandstand and raised seats for spectators. On each side of the ice floor is a spacious raised promenade, with panelled barrier 2 ft. 9 in. in height, separating it from the rink. At intervals along the front of the promenade overlooking the rink rise the massive steel columns which carry the girder roof. They have been covered with white fibrous plaster, have ornate capitals, and form a feature in the decorative aspect of the hall. At the east end these columns constitute an entrance of three bays to the tea-room.

The freezing machinery installation consists of ammonia compressors with brine circulation through continuous lines of steel tubing laid on the insulated floor of the rink. Of such tubes there are about nine miles. These are connected with main pipes, which are carried under the flooring of the promenade, and joined up to the compressors. The cold brine is circulated at a temperature of about 20 to 22 Fahrenheit—representing 10 to 12 degrees of frost according to this scale, and there will be on the floor a sheet of ice of from 5 to 6 inches in thickness. The ammonia compressors and a Diesel oil engine, which supplies the driving power, are placed in a special engine room at the west end of the rink. The Diesel engine is of 100 horse-power; the fly-wheel of the compressors has a diameter of 10 ft., and a 9-rope drive. Above the engine room are a large water tank and something like 20 tons of condensing pipes. At the same end is a boiler house for the purpose of supplying hot water to heat, by means of radiators, the promenade of the ice rink, the tea, dining, and other rooms. The construction of the rink and the provision of the machinery have been carried out by Messrs. W. M. Anderson and Co., engineers and architects, Glasgow. The cost of the building and machinery has been £18,000.

ON, BART., M.A., F.R.I.B.A.

CONCRETE AND STEEL SECTION. (MONTHLY.)

ECCENTRICITY OF BEAM REACTIONS ON COLUMNS.

by OSCAR FABER, B.Sc., A.M.I.C.E., and P. G. BOWIE.

In what is generally, if rather vaguely, described as "constructional engineering," knowledge is more deficient as regards the behaviour and strength of columns than of any other unit. This applies equally to columns of steel, reinforced concrete, and timber, or other materials.

The difficulties are chiefly connected with the following problems: (a) Determination of eccentricity of beam reactions; (b) buckling tendencies; (c) determination of transverse tensional stresses (or the design of the web or ricing of steel stanchions and the cross bending in concrete columns).

In the present article, it is only proposed to deal with the first of the three problems mentioned above. Its importance will be realised at once when it is remembered that in the case of a rectangular homogeneous column or strut, the maximum stress due to a load applied at one edge is four times as great

probably it does not alter the conditions appreciably; where, however, it is made strong and stiff, its effect would be to prevent the beam deflecting without pulling the top of the columns over with it. This necessarily implies a greater moment, and therefore a greater eccentricity on the column, which may then be analysed as in (2) (below). Not infrequently, such top brackets must be considered as weakening the column, and detrimental rather than the reverse to the stability of the structure.

CASE II. I

The calculation of the eccentricity of the reaction from a beam monolithic with its column is much more difficult, and had not, up to the present, been dealt with in any published literature. It has therefore been very fully analysed by the authors in Faber and Bowie's "Reinforced Concrete Design" (Edward Arnold, London, 1912), in very general terms, taking into account unequal loading of monolithic floors, allowing for dead and live loads, stiffness of beams, columns, etc., and various other considerations. Such general equations are necessarily complicated, if they are to be exact, and are therefore well left as an appendix, from which simplified formulas and curves are given for various cases likely to be met in practice.

In the present article, it will not be attempted to review the mathematical derivation of formulae, which may be referred to if required. It is thought that more generally useful results will be obtained, in the space available in these columns, by selecting one case and working this out in detail with a view to showing what eccentricity is obtained. A building has been selected, having proportions quite common in practice, and the eccentricity of the outside columns will be studied, since on these the eccentricity is most marked. The formulae in the treatise referred to contain the

expression $\frac{W_d}{W_t}$ the ratio between the dead load of the floors, and the total load dead plus live, to which they may be subjected. While for interior columns this is a factor of fundamental importance, it is important to a much less degree for outside columns.

As regards outside columns, this factor comes into play in so far as the condition of loading on the second bay affects the deflection of the outer bay. Obviously

the greatest deflection of the outer bay takes place when it is fully loaded, and when the second bay has its dead load only.

Hence in the present example a further simplification will be made by considering only the case of all bays fully loaded (equivalent to putting $\frac{W_d}{W_t} = 1$). This simplification is always made in the design of steel-frame buildings.

With these reservations it is shown that the moment on outside columns is given by

$$M = w l^2 \frac{1 + 6D}{12(1 + 10D + 20D^2)} \quad (1)$$

where w = total load on beam per unit of span

l = span of beam

$$D = \frac{B}{KC}$$

B = Moment of inertia of beam divided by its length.

C = Moment of inertia of column divided by its length.

K = a constant.

The quantities B and C are measures of the stiffness of beam and column respectively. The constant K depends on the condition of the end of the column at its junction with the floor above or below that under consideration.

If it were free at this junction as at 2 (a) $K = 3$, if fixed in direction as at 2 (b) $K = 4$, and if constrained to have the same slope as the floor considered 2 (c), $K = 6$.

For outside columns the latter condition applies very approximately when all floors are loaded, and will be taken in the present example.

When the column extends both up and down from the joint considered, as it does from the lower floor of Fig. 2c, its stiffness is proportionately increased, as the section above has to be strained as well as the section above. The value of $K C$ in formula (1) is then to be taken as the sum of the $K C$ s applying respectively to the upper and lower tier.

Full particulars of the building under consideration are given in Fig. 3.

The sections of beam are taken so as not to exceed stresses of 16,000 and 600 lb. ins. in the steel or concrete respectively.

The moments of inertia of the beam are 27,875 ins⁴. and 71,600 ins⁴. in roof and lower floors respectively, these moments being expressed in units derived from areas of concrete, thus requiring

Fig 1

if the same load were centrally applied. This eccentricity is frequently exceeded in common practice.

For the present purposes, it will be convenient to classify joints between beams and columns under the following heads: (1) Where the beam rests upon a bracket; (2) where the beam and column are monolithic, as in reinforced concrete, and have the same slope impressed upon them by any straining conditions to which they may be subjected. (3) when the beam rests on the column.

CASE I.

The first type is very common in steelwork and timber construction, as is illustrated by Fig. 1, in which the deflection of the beam is exaggerated for greater clearness. In such cases it is usual to take the eccentricity to the centre of the bracket. It is to be noticed, however, that where the deflection is great and the bracket stiff, the eccentricity will be greater than this, its maximum value being, of course, the distance from the edge of the bracket. Usually the error involved by taking it at the centre is not great.

In steel construction, it is common practice to have a small angle bracket above the beam, as well as the large one on which it rests. Where this is bolted,

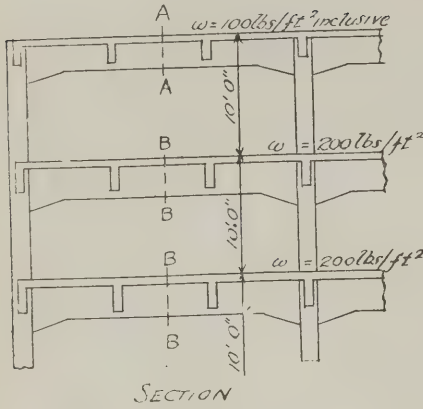

Fig 2

PART PLAN

SECTION AA

SECTION BB

Fig 3

to be divided by 15 = $\frac{E_s}{E_c}$ to express the moments of inertia in terms of areas of steel.

In the design of the columns, exactly 2 per cent. of longitudinal steel will be used, in the form of four bars, the centre of the bar being $\frac{d}{8}$ from the edge, as in Fig. 4 :—

The reaction of the beams on the outside column are 28,800 lb. and 57,600 lb. in roof and floors respectively.

The quantity wl^2 in formula (1) is 16,600,000 ins.-lbs. for roof and 33,200,000 ins.-lbs. for floors.

The solution of the stresses in an outside column therefore, of any selected size, reduces itself into the calculation of its equivalent area, and its moment of inertia.

From the first, the direct stress may be simply determined, while from the latter $D = \frac{B}{KC}$ becomes determinate, enabling formula (1) to be solved. From this moment, the stress due to eccentricity may be easily calculated.

The analysis will be made *in extenso* for one case, and the results given for the others.

Consider the case of an 18 in. column on both tiers.

For this the area as steel

$$A_s = \frac{2 \times 18^2}{100} = 6.48 \text{ ins}^2.$$

Equivalent area

$$A_e = 18^2 + 14 \times 6.48 = 415 \text{ ins}^2.$$

Moment of inertia (concrete units)

$$I_c = \frac{18^4}{12} + 14 \times 6.48 \times 6.75^2 = 12890 \text{ ins}^4$$

$$\therefore C = \frac{I_c}{l_c} = \frac{12,890}{120} = 107.4 \text{ ins}^3$$

$$\therefore KC = 6 \times 107.4 = 644 \text{ ins}^3$$

$$B = \frac{I_b}{l_b} = \frac{27875}{288} = 96.8 \text{ ins}^3$$

$$\therefore D = \frac{B}{KC} = 0.15$$

From this we can solve from formula (1) for the moment in the column

$$M = \frac{wl^2}{12(1 + 10D + 20D^2)} = 16,600,000 \times \frac{1}{18.56} = 891,000 \text{ ins. lb.}$$

Hence stress due to bending

$$= \frac{891,000 \times 9}{12890} = 622 \text{ lbs.-ins.}^2$$

Stress due to direct load

$$= \frac{28800}{415} = 70 \text{ "}$$
$$\frac{692 \text{ "}}$$

The actual value of the eccentricity is evidently the moment divided by the load, and is

$$e = \frac{M}{P} = \frac{891,000}{28,800} = 31 \text{ ins.}$$

These figures apply to the upper tier immediately below the roof beams.

Coming now to the column on the lower tier—that is, immediately below the highest floor—we have for the same section of column, which will, of course, have the same equivalent area and the moment of inertia.

$KC = 2 \times 644 = 1288$, as we now have the upper and lower tiers to consider as regards stiffness.

The beam on this floor is heavier, and

$$B = \frac{I_b}{l_b} = \frac{71600}{288} = 249 \text{ ins}^3.$$

$$D = \frac{B}{KC} = \frac{249}{1288} = 0.193$$

whence from formula (1)

$$M = 33,200,000 \times 0.049 = 1,625,000 \text{ ins. lbs.}$$

This moment is resisted half by the upper and half by the lower tier, so that stress due to bending

$$= \frac{812,500 \times 9}{12890} = 558 \text{ lbs. ins.}^2$$

stress due to direct load

$$= \frac{86400}{415} = 208 \text{ "}$$
$$\frac{766 \text{ "}}$$

Fig. 5
Column Stresses in Tier below Roof

The value of the eccentricity is

$$\frac{1,625,000}{57,600} = 28.3 \text{ ins.}$$

Consider now the floor below. It will be found that for the same size column, we have the same value to B K C M, and therefore to the stress due to bending and the eccentricity of the floor reaction.

Evidently the direct stress will be increased in direct proportion to the increased load, and will be $208 \times \frac{5}{3} = 346$.

The constancy of the eccentricity applies also, for this size column, to all the lower floors.

These calculations have been made fully for the 18 in. column to show the method clearly. Without giving further calculations, the results will now be given for other columns.

The stresses due to direct load and bending for columns of various sizes in the upper tiers are given on a curve in Fig. 5.

They are given for the tier below in Fig. 6. This curve applies to all floors

below as regards eccentric stresses, and the direct stresses, for a given size column, will of course vary with the number of floors above it.

The actual value of the eccentricity is given for the different columns in Fig. 7.

It must be remembered that on all floors except the top, the bending moment represented by this eccentricity is taken up partly by the lower tier and partly by the upper tier, the stresses due to it being therefore only about one-half what they would be when this is ignored.

It is interesting to consider several points brought out by the results now before us. Consider, for example, Fig. 5.

It will be seen that the size of the column giving a stress of 600 lb.-ins.² and ignoring the eccentricity—which we fear has not infrequently been done—is about 6½ in. square. The actual stress in such a column is about 1,240 lbs.-ins.²

The column required to keep the total stress down to 600 is about 19½ in. square. Note the fact that the eccentric stress first increases directly with the size of column, then rounds off to a maximum

and diminishes. The reason for this is that where the column is very slender the slope at the end of the beam is determined by the beam alone, and in that case the eccentric stress in the column varies directly with the distance of the outer fibre from the neutral axis.

When, however, the column becomes stiffer, it reduces the slope of the joint, and then the eccentric stress is of course, reduced also.

Note, also, the curious shape of the total stress curve, which shows that between the limits of 6 and 12 in. the maximum stress is reduced very little by an increase in size.

CASE III.

When the beam rests on the column (Fig. 8). It does not appear to be generally understood that a column supporting a beam which rests on top of it has any eccentricity at all. When, however, it is considered that the beam necessarily deflects, it is obvious that the load will be taken entirely on the edge of the column unless the latter bends or gives. Assuming the beam was resting uniformly on it before being loaded, this assumption is made in all that follows, and will be practically correct in first-class design and workmanship.

It is necessary to differentiate between cases in which the connection is so rigid and strong that the beam will at no point be lifted off the column and cases where this can occur (as in Fig. 8). In the first of these cases, the construction behaves as monolithic, and may be calculated as for case (2).

When the joint is not so rigid, the eccentricity of the roof beam reaction will be between zero and half the depth of the column. The best way to determine it, is to calculate it as in case (2) as a monolithic construction. If it is found that the eccentricity is so small that no tension is developed at the back, the joint will not open, and the eccentricity calculated is correct. If, however, tension is developed, the joint will open, and the eccentricity thereby be increased, though it will be in no case exceed $d/2$ (unless brackets are put on).

Consider now the joint on the lower floor. Calculate the stresses as a monolithic construction (case 2). If the eccentricity is so small that no tension is developed the joint will not open, and the stresses are as found. If it opens, the moment on the lower tier may attain to the total load at a leverage of $d/2$. This is evidently an eccentricity of much more than $d/2$ when expressed in terms, not of the total load, but, as usual, of the beam reaction at that floor. For this reason, this eccentricity rapidly becomes so large as to equal that obtained by considering the structure monolithic, in which case it behaves as such, and does not open. It is thought that the treatment outlined is so simple as not to warrant a numerical example.

It may be stated that, with the usual proportions of beams to columns and with usual spans and loads, the roof joint will always open, the joint at the floor below generally so, while floors below that, again, will generally behave as if monolithic.

TEST OF FLOORS ON THE "DENTILE" SYSTEM.

A very successful test was carried out, on March 7th, on the floors which have recently been constructed by Messrs. H. Arnold and Sons, contractors, Doncaster, for the Midland Carriage and Wagon Works, Washwood Heath, Birmingham. These floors have been constructed on the Dentile system, which is controlled by the Indented Bar and Concrete Engineering Co., Ltd., of Westminster. The feature of the floor is the

use of hollow tiles, which have the effect of greatly lightening the floor itself, and at the same time making it soundproof without the use of projecting beams either of steel or of reinforced concrete. What is called the "two-way" Dentile floor is easily capable of spanning over areas up to 30 ft. square or more without any beams, and without being unduly thick. The tests in question were two in number. The first test consisted of a square floor reinforced in both directions 17 ft. 10 in. by 16 ft. 7½ in. The working load for which this floor was designed was 100 lb. per sq. ft., but it was arranged to test the floor up to 1½ times this load—namely, 150 lb. per square foot. This load was considerably exceeded during the test. The material by means of which the load was placed upon the floor consisted of cement sacks, and in all exactly 20 tons were placed on this floor, which is giving a load of 152 lb. per sq. ft. The deflection was very carefully measured, and increased quite gradually during the progress of the test to 0.07 in. While the full test load was still on the floor the centre of the floor was exposed by the removal of a sack of cement, and five heavy blows with a piece of timber 18 ft. long (9 in. by 12 in.) lifted to a height of 2 or 3 ft. and banged down upon the floor by the united efforts of five men, were given to it. The floor withstood this extremely severe test admirably.

The next test took place on a small similar room, 16 ft. 7½ in. by 13 ft. 10 in., in which the floor was constructed on the one-way system; that is to say, it was only reinforced in the smaller direction, there being no reinforcement whatever in the direction at right angles to this. The full load—which again was 1½ times the working load—consisted of 17.2 tons, but the deflection in this case only amounted to 0.01 in.

The extreme success with which these floors of both types withstood not only the heavy test load, but also the test for shock, affords the best possible proof that Dentile floors are suited in every way both to the carrying of heavy dead loads, and to heavy falling loads with a

minimum deflection and vibration. The floors are quite economical, and the surface afforded by the tile for plastering is exceptionally good. The absence of beams over large spans enables the ceiling treatment to be carried out with great ease.

TESTS OF CONCRETE SLABS.

Tests of concrete slabs 20 in. square and 2½ in. thick, described in a paper by Messrs. S. M. Dixon and P. W. Villiers, recently published by the Institution of Civil Engineers, showed for plain concrete that, if the strength of the slab supported on two edges and subjected to a concentrated load, is taken as 1, then the strength when similarly supported and carrying a uniform load equals 2. When the slab is supported on four edges and carries a concentrated load the strength equals 2, and when supported on four edges and carrying a uniform load the strength equals 4. These rules only apply when the slab is evenly bedded—that is, when, as in practice, it is made in one piece with the cross girders. With specimens of different thicknesses tested on four edges the transverse strength varies approximately as the square of the thickness, when this is small, increasing slightly more rapidly for thicker slabs. The strength of reinforced concrete slabs was found to vary greatly according to the kind of reinforcement used.

THE CONCRETE INSTITUTE.

A meeting of the Concrete Institute took place at Denison House, 206 Vauxhall Bridge Road, Westminster S.W., on Thursday evening, March 14th, 1912, Mr. E. P. Wells, J.P., vice-president, in the chair.

The following were elected members:—Mr. Victor Alden, London; Mr. Reginald Birkett, Manchester; Mr. Alfred Cordery, London; Mr. Alexander T. Cranmer, Twickenham; Mr. Robert Gillies, Kingston, Jamaica; Mr. Charles A. King, Edinburgh; Mr. Alfred Wadsworth Lovell, Hull; Mr. A. C. Hughes, who resigned at the end of 1911, resumed membership. For the paper read, see page 335.

THE DENTILE FLOOR: VIEW OF CONSTRUCTION WITH "L" TILES.

TESTING OF MATERIALS USED IN REINFORCED CONCRETE.*

BY A. ALBAN H. SCOTT, M.R.San.Inst.

The author had been asked to give a paper on the "Testing of Building Materials," but had abandoned the idea of considering building materials in general in favour of the subject now chosen.

The necessity for some very serious consideration of this subject had been particularly impressed upon his mind, in view of the fact that certain figures are being laid down as the ultimate strength of concrete by the various reports and regulations issued comparatively recently.

Laboratory Tests, and Others.

THESE figures seem to have been based upon results obtained from laboratory made specimens only, made under the most favourable conditions, without any allowance for the more or less rough methods which only are obtainable at present on the actual construction. In making some of the laboratory test specimens the materials are very accurately gauged, thoroughly and evenly mixed, and, in lieu of the ordinary punning and slight ramming (if any) which you get on the works, they are subjected to pounding down with a heavy hammer, and thus getting an artificial result, a result which is impossible to attain under the most perfect conditions obtainable on even a perfectly organised job.

The test results which he intended to describe were such as could be reasonably expected from work executed under a specification such as was published last year; but even these results can only be expected if professional supervision is given, not only to the general work, but also to the most minute points.

Reinforced concrete demands greater study than any other material used in constructional works. Architects, except for a comparative few, have until recently been too slow in making themselves acquainted and proficient in this class of construction. Engineers were still worse; and clerks of works and general foremen who are really fit to take charge of a fair-sized job of reinforced concrete are few and far between. All this, however, is now being rapidly changed, and it has been realised that concrete and reinforced concrete are entirely different materials.

Procedure in Testing.

It has always seemed to me to be inconsistent to take elaborate precautions to obtain cement of a high and even quality, and treat the other component parts as if the ultimate strength of the concrete did not also rely upon their influence.

The following is an outline procedure I would suggest should generally be adopted with regard to the Testing of Materials for Reinforced Concrete work:—

All tests to be made at an independent testing and experimental works.

The cement to be tested from samples taken from the bulk, such samples being taken from various positions of the bins at the makers' works. After the cement has arrived on the job, samples are again taken from various bags, thoroughly mixed, and again tested. Further tests made from time to time as the material is being used in the works, the number of these tests being regulated by the quantity of the consignment, and the time taken in using same.

All tests on cement should be made in accordance with the latest specification of the British Standard Specifica-

tion for Portland Cement, with the further test for ascertaining resistance to thrusting stress of both neat cement and also cement and sand, in the same proportions used for the tensional briquettes.

Aggregate or Coarse Material.

A sample in bulk to be delivered on to the works, a sample taken and tested: 1st, for freedom from loam and other foreign matter; 2nd, for the proportion of the various sizes of the crushed material; 3rd, for the amount of voids; 4th, for specific gravity. Tests repeated on the material being used in the works from time to time as may be considered desirable.

Sand and Water.

Sand to be treated in exactly the same way as aggregate, and in addition a test for the amount of material that will pass a sieve of 1-50 in. by 1-50 in. apertures should be ascertained; this, which can be called "flour," should be rejected.

Water is tested to see that it contains no unusual or injurious properties.

Steel.

Steel to be first inspected at the makers' works with a view to ascertaining: 1st, whether welds have been made; 2nd, for surface defects; 3rd, correctness of diameters.

Every rod over $\frac{3}{4}$ in. diameter must be stamped with a die as having been inspected. Sample lengths are taken from the actual rods, which are duly stamped and sent to the testing works for the purpose of ascertaining: 1st, their ultimate strength; 2nd, their elastic limit; 3rd, their elongation and contraction of area; 4th, to observe the structure of the metal at fracture, whether the same is silky, granular, or fibrous. 5th, bending test. All these tests to apply to rods and wire from and including 3-16 in. diameter and upwards.

Concrete.

The test specimens of concrete should be of a standard size of 6 in. cube. Six specimens made for each test, three made in the laboratory and three on the works. The cement for each six sets of specimens to be taken from the same consignment. The laboratory test specimens should be made as far as possible on practical lines, so that the result should be such as can be reasonably expected from concrete in the actual work.

All specimen pieces made on the works should be made from concrete taken from the actual mixing platform. All such specimens should be made in metal moulds, and the concrete worked in by punning and tamping to the same degree as has actually taken place in this structure. Six test cubes should be used for each test, and the minimum tests should be made at the following periods: 7, 28, 56, and 90 days and 1 year.

For the purpose of record and research work such tests should be carried out at the following periods: 7, 28, 56, and 90

days; 6, 9, and 12 months; 2, 3, 4, and 5 years.

Centering.

No mechanical tests are required for this, but when the strutting is being placed into position, rough calculations should be made to see if any undue deflection or movement is likely to take place during the process of placing the moist concrete into position, and inspection made to see that the joints have been properly filled up by rubbing with hard bar soap or other material to prevent dripping of the cement and sand.

The Function of the Materials.

We might now consider whether the tests mentioned above are reasonably required, and before proceeding to do so, a few remarks on the work the material is called upon to do may not be out of place. In reinforced concrete the concrete takes compression and shear; the steel taking all the tension and assisting for shear and compressional strains. The concrete being stressed to not more than 600 lb. per square inch in compression, and 100 lb. per square inch in shear; the steel in compression in beams not more than nine times per square inch that of the adjoining concrete, and in columns not more than fifteen times that of the adjoining concrete and steel in tension 15,000 lb. per square inch, and the adhesion of the concrete to the steel 100 lb. per square inch of actual contact.

These figures being subject to various conditions, such as the efficient tying in of the steel in compression to prevent bulging of the rods, and proper proportion of metal to the concrete and spacing of the steel. In the case of columns the effective area of concrete is only taken as that part which is hooped in by the ties to the vertical steel members.

If we are working to a factor of safety of a fourth of the ultimate, the ultimate resistance to thrusting stress of the concrete should be not less than 2,400 lb. per square inch, the resistance of concrete to shear 400 lb. per square inch, and the steel 60,000 per square inch ultimate tensile.

These figures show that all the materials are called upon to be of high efficiency, and to work in harmony and simultaneously together, and have been adopted in consideration not only of their ultimate resistance but also the relative coefficient of elasticity.

The work is designed on the assumption that the materials actually used are capable of resisting these stresses.

The following are a few reasons why the author considers the tests necessary:

Aggregate and Coarse Material.

It has been found that most aggregates (unless washed) contain loam and other foreign matter. A sample of river aggregate recently tested gave as much as 7 per cent. of loam, and most loams have a surprising covering power, being of the very finest of "flour," and consequently when the cement is added there is a thin film between the cement and the actual silicious material, thus preventing the cementing together of the particles. Some time ago it was advocated in certain quarters that the presence of loam in aggregate did not decrease, but rather increased the strength of concrete. A slight mistake was made there. The material which was mistaken for "loam" actually contained certain cementing properties which had the effect of making the concrete a richer mixture.

With aggregates which are practically uniform in size, or if the various sizes are not properly graded, proper bond is not

*Extracts from a paper read before the Society of Architects, March 7th.

obtained between the various materials as the mortar is concentrated, and thus a portion of the mixture is deficient in cementing materials; therefore it is most desirable that the grading and voids should be worked out very carefully; and with certain exceptions, it is found, within limits, that the grading which gives the smallest amount of voids in the aggregate and sand results in concrete of greater strength. With aggregate and sand containing a high percentage of voids, a greater proportion of cement is required. [A diagram was shown illustrating the extraordinary differences in percentages of voids contained in various kinds and sizes of materials.]

Thrusting Stress.

It should be remembered that as the number of particles increase, so the proportion of the cement to the whole should be also increased owing to the greater covering power required. A test cube made with a very small amount of aggregate and a large amount of sand, with the usual proportions of cement, gave an ultimate resistance to thrusting stress of only about 600 lb. per sq. in., such low result being entirely owing to the fact that the usual amount of cement in that case was not sufficient to cover properly each particle of the sand and aggregate, and a perfectly cemented and homogeneous mass was not obtained.

The ultimate resistance of any material is its strength at its weakest point, and the actual area of the concrete is the gross area minus the area of voids at any section; it is therefore necessary that the ascertained percentage of voids in the aggregate and sand should be entirely filled up with cement, with an additional allowance for completely surrounding each particle. The usual rough and ready means of determining the exact proportion of the cement to the sand and aggregate has resulted in many cases of disaster.

Specific Gravity.

The specific gravity of sand and cement should be taken in order to compare with the weight of the test specimens, as such weight is materially affected by the original weight of the aggregate and sand. There are at least two methods of ascertaining the amount of voids. One is by ascertaining the specific gravity of the material used; and secondly, by allowing the aggregate and sand to absorb moisture then to dry the surfaces without extracting moisture from the material, and then in the test tubes to add water until such time as the level of the aggregate and the water is at the same point.

Quality of Steel.

In no part of the steel for reinforced concrete should welds be allowed. Welds can be made in various ways, but it is impossible to test each weld, and in these joints it is not an exaggeration to say that not one weld in 500 would be of equal strength to the rest of the bar, and it has been ascertained with most disastrous results that the strength at the point of the weld goes as low as 30 per cent. of the bar adjoining. This is caused not so much by the lack of amalgamation of the material itself, but generally by the fact that large voids occur right in the centre of the joint.

Surface defects in steel are often found in the ordinary commercial bars, being indicated by most minute cracks, generally starting in the shape of a "V." Although such defects are in themselves perhaps almost innocent, yet immediately the

material is subject to any stress they develop in a most alarming manner.

It has been found that the diameters of bars vary from that specified, resulting in one case in a loss of 12 per cent. in the area. Excess diameter is also often met with; and as the final measurements are taken on a basis of the correct diameter, such excess of diameter will often be the solution of the difference found between the surveyor's measurements and the weight alleged to have been used by the contractor. Reinforced concrete work being designed on the assumption that the whole of the materials employed are exactly in accordance with the specification, a reduction in area of the bars is most serious.

The ultimate strength should be taken at not less than 60,000 lb., and not more than 72,000 lb. per sq. in. It is necessary to keep a very careful watch upon every piece of steel that is brought on to the site.

The elastic limit is also of the utmost importance, as although steel might have a high ultimate resistance, the elastic limit might be so low that in case an accidental load is placed on the work, a sudden collapse might take place; whereas by use of material with a proper elastic limit, proper warning would be given before its sudden failure.

It is essential that steel should be of such properties as will enable it to take a gradual and uniform extension, thus indicating a uniformity of quality; and the contraction of area at fracture should not be less than 45 per cent., which will confirm the properties of equal extension.

A silky fracture indicates a uniformity and a good mild steel so far as the metal, as metal, is concerned. Granular or fibrous grain indicates brittleness and unequal quality.

Vagaries of Concrete.

I think it is safe to say that of all materials used in the building trade, concrete is liable to and does vary more than any other material. Even if every care has been taken to see that each unit is of its proper quality and strength, yet we have in the finished concrete to reckon with a very large amount of human element. One gang of men may produce concrete of the best quality, and another gang on the same work with similar materials may give very indifferent results. This depends a very great deal upon the head ganger, and upon the foreman who selects such ganger. With a good machine-mixer, the possibility of human errors is considerably decreased, but at the same time an improperly designed mixer is, in my opinion, more dangerous than mixing the concrete by hand.

A table was presented showing that concrete which has its setting somewhat retarded by sprinkling with water gives generally higher results than concrete which was allowed to dry under normal conditions. The question arises here, however, as to the consistency of concrete not only from the point of view of the strength of the concrete itself, but rather as to what consistency will give the best results in actual practice from the point of view of contact with the metal, resistance to crushing and shear; and although it is essential that as little water as possible should only be used, to prevent air-holes occurring after the water has been evaporated, I would feel inclined to use a concrete slightly wetter than as in the average practice in France, but certainly much drier than that generally used in England.

Comparatively wet concrete will not allow of its being rammed or "tamped", whereas, to get a drier concrete into its correct position, tamping and gentle ramming is essential. As the whole of the strength of reinforced concrete depends upon proper adhesion of the concrete to the steel, it is an essential factor that the concrete is gently rammed at every point.

The architect has therefore a much better chance of making sure that the concrete is properly placed in position and properly worked between the reinforcing metal, and the greatest trouble has been found to be with contractors wishing to make the concrete wetter than is desirable owing to the fact that a wet concrete is more easily placed in position with much less labour than a dry concrete.

A Seven-day Test Essential.

The usual period of the first test on concrete has until recently been at 28 days, but with important structures, to obtain tests at 28 days after the concrete is made is not going to be of very much use for early correction when the work is being rapidly pushed forward, and therefore a seven-day test is essential, so as to be able to detect immediately any error in any of the material.

At the present moment there are few tests at seven days, so that for the present the reasonable resistance of concrete at this period has not been definitely ascertained. Such tests in connection with the 28 days' tests will also give most useful information with regard to when it is safe to strike the centering; and, when one considers the failures that have taken place owing to the centering having been removed too quickly, a seven days' test will undoubtedly become a recognised factor very shortly.

The 56 days' and 90 days' tests are desirable, as they show what is actually taking place in the work with regard to the increase or decrease in the strength of the structure.

The concrete up to about six months of age increases in strength fairly rapidly, but it is curious that from about six to nine months the increasing resistance to thrusting stress is very trifling, but after nine months the strength of the concrete again continues to increase at a more rapid rate, although not so rapidly as during the first six months.

For the purpose of research work, and where the importance of a job will allow it, it is most desirable that specimen pieces should be made in sufficient number so that each series of specimens are tested up to at least ten years of age; a number of specimens should always be kept, so that if anything should ever happen to any structure or part of same one is in a position to test the concrete, and the steel, of course, could be tested from samples obtained from the actual work.

From the detailed results of experiments to ascertain the resistance of the thrusting stress on 64 cubes made under various conditions at Mr. Kirkaldy's works, many things might be learnt. At 28 days the highest result obtained was an average of 2,225 lb. per sq. in., and at 90 days the highest result was 3,554 lb. These two results can be taken as being the greatest amount of resistance that can be obtained from concrete made under the most favourable conditions, and it should be compared with the lowest results obtained, which are 1,026 lb. per sq. in. in 28 days, and 1,787 lb. per sq. in. in 90 days, with varying results between these two extremes; and the question arises as to which is the most probable result that would be obtained from

work in actual practice. In determining this it might perhaps be desirable at the same time to inspect the diagrams showing the results of experiments on concrete taken from the actual mixing platform on several works.

The Finished Structure.

A word with reference to the testing of the finished structure may not be out of place. Specifications often provide for the work to be tested with $1\frac{1}{2}$ times the load which the work has been designed to carry; a factor of safety of four is taken in the calculations to provide for inequalities of workmanship and materials, for allowance for fatigue of material under strain, and for isolated accidental excess loading—considering that with $1\frac{1}{2}$ times the safe load the concrete in compression is working up to 900 lb. per sq. in.; adhesion 150 lb. per sq. in.; 200 lb. in shear, and steel varying up to 22,500 lb. per sq. in. in tension, that by the application of such loads, the parts so tested may be permanently injuriously affected.

If the materials are tested as suggested in this paper, and professional supervision is given to the work, tests on the finished structure are not necessary; if it is desirable, then only the safe load should be applied, and if no undue deflection takes place no further loading can serve any useful purpose.

DISCUSSION.

Professor Henry Adams, F.S.I., M.Inst.C.E., in proposing a vote of thanks, said that the author was to be commended for emphasizing the need for all tests to be in accordance with actual practice rather than under laboratory conditions. It was for practical use that tests were wanted, and in all cases the conditions in actual practice should be taken into consideration.

In the course of a detailed discussion of the paper, Professor Adams said he supposed that the welds referred to in the paper were end welds—i.e., for the purpose of lengthening a bar; but there could be no possible objection to the electric welding in the crossing of the various bars. It was where tension came in that welding was objectionable. As a rule the strength of a weld was 80 per cent. of the original bar. The 30 per cent. referred to by the lecturer must have been an exceptional case.

Mr. E. C. P. Monson seconded the vote of thanks.

Mr. David Kirkaldy also supported the vote of thanks.

Mr. S. Bylander said that, with regard to the form of the test pieces, he certainly thought 4 by 4 was not satisfactory, the aggregate used being too large in size to be properly placed; a 6 by 6 would be much better. The strength of steel being 62,272 lb. per sq. in., he would like to know why Mr. Scott limited the tensile strength to 72,000 lb. He did not understand the author's reference to the elastic limit of steel. His (the speaker's) idea was that it was necessary to have a high elastic limit, because it was really that which determined the safety of the structure, and not so much the ultimate strength of the material. They did not wish to have a very hard steel, because it was brittle.

Mr. G. A. T. Middleton said it had rather surprised him that both Mr. Scott and Prof. Adams had remarked upon the fact that cement was now tested by weight per cubic ft., and he thought it would be very much better to test by specific gravity.

Mr. P. M. Frazer, said that the general contractors had taken to reinforced concrete construction as ducks took to water, and he wished the same could be said of the professional man. It was quite remarkable to go on a job and see the way in which the contractors turned out consistently good work with better results than could be boasted of by those on the Continent or in America. The difference between hand mixing and machine mixing was very real, and an analogy might be drawn between a stoker of a boiler and a stoking machine, the latter giving far better results than the human stoker.

Mr. J. Herbert Pearson said that Mr. Scott had called attention to the difficulties which arose in getting a joint between two sections of reinforced concrete dealt with on two separate days; but the speaker thought that, under certain conditions, it would be impossible for the second section of concrete to follow immediately after the first, and in those circumstances he would like to know what the lecturer would suggest to get over the difficulty of preventing any water percolation.

Mr. H. T. Cover asked whether Mr. Scott had made any experiments regarding the strength of concrete floors. He came across a case recently where some workmen were lifting a load of two tons on a jack with a base 4 in. square placed between two steel joists 5 by 3 of 4 ft. span and 4 ft. apart, with six inches of concrete.

Mr. Percy B. Tubbs remarked that the supervision of reinforced concrete work put additional responsibility on the architect, who, if he undertook such work, should be paid not only for his professional services but for acting as clerk of works also.

Mr. A. Alban H. Scott, in the course of his reply, said that with regard to the question of the weight of cement, he believed that in the original report of the R.I.B.A. Sub-Committee on Reinforced Concrete, the weight was specified 76 lbs. per cub. ft., and the tests in the tables referred to were made under the same conditions, and since then the 90 lb. had been adopted. The question of the weight or measure of cement was far from satisfactory, however, and as Mr. Frazer had said, they always adopted a method of testing the weight of cement per cub. ft., and they would see at the bottom of one of the tables he showed the extraordinary results they obtained. They so increased their cubic measure as to accommodate not less than 90 lbs. It was a fairer way, both to the contractor and to the client, and it certainly got rid of carelessness on the part of workmen in throwing aggregate into the measure. There was enormously hard wear on any form of weighing machine; the scales must be out of truth within two or three days of their use. The only real test on the job was a test of the structure, and that he was dead against unless they could load to the superimposed load for which the structure was designed; and he almost hoped that when the L.C.C. regulations came into force some of the work which would be subjected to a test of $1\frac{1}{2}$ would collapse without loss of life, because in his opinion it was asking for trouble, and weakened the structure. Mr. Kirkaldy had very kindly lent some of the test specimens before them, and had offered to explain them at the conclusion of the discussion. He was glad to hear that Mr. Bylander did not agree with the 4 by 4 cube for testing. It was not sufficiently large for testing with the aggregate they

were using—namely, $\frac{3}{4}$ in. The reason he advocated a 6 by 6 cube was that it was better made and was more of a shape which was adopted in work generally, and with a circular column they were all the time tending to get a very much better and more consolidated mixture than they did with the square one, because in the former they could ram so much better than with the latter, and with the square one they could not get into the corners. With a 6 by 6 by 12 a double quantity of material would be required, and on a big job the cost of material submitted for testing was quite considerable. He did not think a 6 by 6 by 12 would serve any further purpose than a 6 by 6 cube. The former was apt to bind the material for perhaps one-hundredth part of a second longer than the latter, which was quite large enough to give them results which they could reasonably expect to get in a job. Mr. Bylander had asked why he limited the strength of steel to 72,000 lb. His answer was that if they got it above that, there would be a tendency to increase the carbon, and with high-carbon steel there was a possibility of a grain forming in the metal. If they increased the strength of steel beyond 72,000 lb. there was a tendency eventually to increase the safe load. It was impossible, he thought, to increase the basis of 60,000, and it gave the steel people a range of 12,000 lb., which was ample. If they allowed them a greater range than that, it opened up the possibility of makers using a foreign loom, whereas with British steel they had a better chance of getting fineness in the metal. The term "Coarse Material" was now used instead of "Aggregate" in all official documents, and he had adopted it.

HIGH DAMS OF GREAT LENGTH.*

By REGINALD RYVES, Assoc. M.Inst.C.E., M.C.I.

The special study which the author of this paper undertook, and on the results of which this paper is based, was a study of high masonry dams of such length that they may be regarded as dams proper, and in no sense as structures partly held up to their work by the sides of the river valleys. While the great size of the two dams contemplated rendered economy of material an important matter, this was absolutely dominated by the still more important consideration that the dams must be in all respects stable and lasting. It was also desired to avoid as far as possible the use of Portland cement.

Leaving aside all other considerations arising out of the study, this paper is confined to those connected with the building of dams of a great length, the whole of which length is more than 140 ft. clear of the ground, and a part of which may be as much as 180 ft. or more to hard rock. The height of 185 ft. clear was adopted for purposes of calculation. The subject of the paper is, further, kept within somewhat close limits by the condition that the highest calculated maximum stress in the masonry must not exceed 12 tons per sq. ft., at any rate by Bouvier's computation, though by Unwin's computation a somewhat more severe stress may be allowed.

There are four distinct types of dams for wide valleys, and entirely excluding the

*Extracts from a paper read before the Concrete Institute on March 14th.

dam which is a single arch, in plan, and the dam which is, in its lower part, practically a plug in a gorge. The four types are: (1) The mass dam proper, designed on the ordinary theory; (2) the parallel slice dam, which is designed in exactly the same way, but with more concentrated water loads; (3) Captain Garrett's type, or the dam of arches in which the weight of the arches is partly taken into account, but the dam otherwise designed as a gravity dam with concentrated water loads; (4) the author's proposed thrust buttress dam of arches, in which the whole of the water load is taken by masonry, in direct compression, and neither the weight of the buttress nor the weight of the arch is taken into account as regards stability, except for resistance to sliding bodily when the ground is comparatively soft.

Having discussed in detail the other three types of dam, the author stated as follows the propositions which he himself puts forward. The definite propositions which the author puts forward are:—

(1) That there is no precedent for the building of a mass gravity dam in an unassisted length more than 150 ft. clear of the ground.

(2) That our present ideas as to maximum stresses allow of the building of such a dam for heights only slightly in excess of this.

(3) That since the improbability of the stress actually reaching $p \sec^2 \phi$ increases as the slope at the down-stream toe is flattened, we may, for heights above 150 ft. and for angles flatter than 45° , allow one maximum computed stress for $p \sec^2 \alpha$, and a computed stress for $p \sec^2 \phi$, some 50 per cent. higher. This applies both to mass gravity dams and to parallel slice gravity dams, and perhaps also to Captain Garrett's battered buttress type.

(4) That interrupted dams, the gaps being spanned by horizontal or inclined arches, or by beams, offer the important advantages—

(a) Economy of material; (b) absence of contraction cracks and temperature stresses; (c) maintenance of waterway during construction; (d) cheapness of sluices; (e) in some cases a wider choice of materials and of methods of building; (f) and that the interrupted dam, or dam of spans, may be considered as an alternative to the mass gravity dam for great heights, especially as regards the height clear of the ground.

(5) That the author's design for a thrust buttress dam is suitable for heights up to 200 ft., with materials allowing of a compression stress of 10 tons per sq. ft. and up to 300 ft., if a stress of about 16 tons per sq. ft. be allowable.

(6) That none of the dams at present built are thrust buttress dams, either as regards the method of building or in practical effect.

(7) That in order to avoid tension near the upstream toe of a high mass dam, or of a gravity buttress in a dam of spans, it is desirable to make the connection with the rock somewhat as follows:—

The upstream third of the base a flat surface with no bonding and no trench;
The middle third bonded, but not deeply trench;

The downstream third effectively bonded with the rock cut in faces at right angles to the thrusts of the masonry.

(8) That when a high dam is to be built with a large part of its total height from foundations below the bed of the reservoir, it may be worth while to relieve that part of the upstream face from water

load by directly draining it through the dam.

(9) That dams in the tropics, or near the tropics, with downstream faces towards the Equator, or facing east or west, may with advantage be provided with temperature skins to a depth depending on the extent to which daily or annual changes in temperature deprive the outer shell of the face of its value, as material resisting compressive stress.

(10) That a long and high mass dam may usually be, with advantage, built with gaps in the masonry across the length, these gaps being filled when the temperature of the dam is judged to be nearly at or a little below its future mean temperature. If cracks are specially to be guarded against, the gaps may be filled at the end of the cool season, and after the temperature of setting has subsided—that is, when the average temperature of the masonry is at its lowest.

(11) That the grading of material in a large dam should be such that the large stones are not "plums" or displacers, but play the part of the stone in ordinary concrete.

DISCUSSION.

The following took part in the discussion which followed: Mr. Charles F. Marsh, M.Inst.C.E., M.C.I.; Mr. Ewart S. Andrews, B.Sc. (Lond.), M.C.I.; Mr. E. Fiander Etchells, F.Phys.Soc., M.Math.A., A.M.I.Mech.E., M.C.I.; Mr. Morgan E. Yeatman, M.A., M.Am.Soc.C.E., M.C.I.; Mr. S. Bylander, M.C.I.; Mr. Maurice Behar, M.C.I.; Mr. A. Alban H. Scott, M.S.A., M.C.I.; Mr. W. G. Perkins, M.C.I., District Surveyor for Holborn; Mr. R. Dudley, A.M.I.C.E.; and Mr. E. P. Wells, J.P., Vice-President, C.E. (chairman).

RANSOME STEEL PILING.

The Ransome-verMehrs Machinery Company, Caxton House, Westminster, have issued a booklet describing and illustrating the Ransome corrugated interlocking steel piling, known as "Type D Section." The metal in this section is distributed so that the neutral axis of the section passes through the centre. The absence of metal on the neutral axis itself results in an exceptional strength for a given weight of material; the practical result claimed being that one ton of this piling when interlocked covers a greater surface area than can be obtained with any other section of equal strength. The section is described as an outcome of an effort to produce a material designed exclusively for piling work, as distinct from the adaptation of an existing section for a strange duty. A Ransome Type D single pile has a sectional area of slightly over nine square inches, whereas a timber pile of equal strength would require to have a sectional area of at least 80 square inches, and would need to displace about nine times as much material, when being driven, as the steel pile would displace. The pile is much easier to drive than timber, and with drawing and re-driving can be pursued

almost indefinitely. These steel piles are all interlocking; the interlock being of such a character that it is watertight, without any necessity for caulking or clay puddle. Hence, for cofferdam and allied construction, only one row of Ransome piling is necessary, as distinct from the usual timber formation of two rows of timber with clay puddle rammed between. For driving, any standard form of pile engine and frame can be adopted, except in the case of light work in soft ground, where the section can be driven in moderate lengths by hand with wooden mauls. For specially heavy duties this system of piling is readily adaptable. The corrugated form of the pile renders it light relatively to its strength, and thus economy of first cost and in freight charge is secured. These piles have been supplied to the new Rosyth Naval Base, now in course of construction.

INTERNATIONAL SMOKE ABATEMENT EXHIBITION.

An important exhibition was opened on Saturday last at the Agricultural Hall, under the auspices of the Coal Smoke Abatement Society. It comprises all the latest appliances for the use of smokeless fuels, both in the house and in the factory. There is a large and attractive display of gas appliances for cooking, for hot-water supply, for the heating of houses, shops, churches, and other public buildings, as well as for furnace work. The fogs of London have been largely diminished in intensity of recent years as a consequence of the rapidly extending use of gas for fuel, but much remains to be accomplished before the air of the metropolis can rival that of Paris or New York, and it is hoped that this exhibition will do a great deal to stimulate the movement in favour of smoke abatement.

OBITUARY.

The late Dr. Phené.

At the last meeting of the R.I.B.A. the decease was announced, at the age of ninety, of John Samuel Phené, LL.D., F.S.A., F.G.S., Fellow, elected 1872. Dr. Phené's archaeological researches in Italy, Greece, Asia Minor, India, and Western Europe are well known, and the results of his labour have appeared in various publications, among others in the *Institute Transactions* of 1873 and 1878.

"What Town Planning Means."

This is the title of a 12-page pamphlet by Mr. George L. Pepler, F.S.I., just issued by the Garden Cities and Town Planning Association. It presents succinctly the valuable features of the Town Planning Act, and indicates the way in which its opportunities may be taken advantage of. Copies of the pamphlet, price 1d. (2d. post free), may be obtained from the Garden Cities and Town Planning Association, 3, Gray's Inn Place, W.C.

The Control of Advertisements.

I have before us the terms of a Draft Bill prepared for introduction into Parliament, if possible, during the present year, under the title "The Advertisements Regulation Act, 1912," a sequel to the "Advertisements Regulation Act 1907," which is referred to as the "Principal Act"; with the intention that, if the second Bill becomes law, the two may be cited together "The Advertisements Regulation Acts 1907 and 1912." The amending Bill is framed by the same Society which framed and brought in its predecessor--the Society for checking the Abuse of Public Advertising, shortly known under the mystical-looking title "Scapa," a shorthand word framed out of the capital letters of the principal words of its title. The reasons for endeavouring to pass an amending Act are that the first Act was found difficult to put into effective operation in some respects, and required its machinery amended; but before considering principles of operation, we may draw attention to the importance of the subject, as affecting generally the enjoyment of life, and in some respects affecting more specially the interests of architects and of architecture. We have become so used to see every available area, many which ought not to be available for such a purpose, crisscrossed with huge and glaring advertisements, that many of us perhaps hardly realise what a difference there would be in the aspect of towns more especially, but to some extent also in the country, if a legal check could be put upon the size and the omnipresence of advertisements. They have become, in their effect on the senses, somewhat like a noise which goes on so continually that our ears cease to notice it, and are only conscious what a nuisance it is when we realise the sense of rest and peace following its sudden cessation. Take the case, for instance, of advertisements in public vehicles. We are used to seeing every panel inside an omnibus or tramcar occupied with advertisements of soaps and other articles, and we cease to think about it, until we realise the sense of order and neatness produced when we get into the tramcar of some company which has preferred to keep its vehicles free of this nuisance. Our railway station walls are covered with disorderly patchworks of ugly pictures advertising goods that most of us do not want; pictures generally of the most vulgar order both in regard to design and colour, amid the crowd of which it is often difficult to find the face of the station. The sight of a good, clean brick wall, such as that which has still been preserved in the recently opened South Station at Waterloo is a kind of oasis. Then there is the interminable succession of huge advertisement pillars of quack medicines along miles and miles of our principal railway lines. We are getting hardened to these, and they are getting to be accepted as part of the natural order of things; but if we could find them all some day suddenly removed, we should become conscious of the improvement they had been to the landscape through which they rain takes us.

In our cities the covering of every hoarding with advertisements has the effect of giving a sordid appearance to the town, especially as the main object with each advertiser is to attract his special advertisement should be more glaring and character than any other. It has been main-

tained by some apologists that these roads' of advertising posters are of more interest than a blank space; but in London at all events there has been a decided move of late years in favour of treating temporary hoardings in an architectural manner, with something like a design in the supports and artistic lettering in the announcements painted on them. All such attempts are rendered nugatory by the presence of a mixed array of posters arranged with neither order nor design. But perhaps the manner in which architectural effect in cities is most injured is by the huge scale of lettering which is constantly seen in the shape of solid built-up letters affixed to the fronts of buildings; letters of a type which would be unobjectionable on a small scale, but which from their huge size destroy all sense of scale in the buildings and in the general appearance of a street. And when at night we lose sight of these, there is provided for our enjoyment a whole army of monstrous flashing advertisements by which night is rendered hideous and all sense of repose and beauty in a lighted city is destroyed.

Our own impression has always been that the best and most comprehensive means of keeping the advertisement mania within at least reasonable limits would have been found in the imposition of a tax in proportion to the surface area of placards or the size of lettering, accompanied by an absolute veto on the use of flashing advertisements at night. The idea of the tax has, we know, been suggested and seriously considered by those who are anxious to see the nuisance reduced, but it appears for some reason to have been discarded as unworkable. Why it should be so regarded we do not understand, unless it is supposed that Parliament would not be likely to sanction it. In Parliament there are, of course, objectors to everything, and there are always influential upholders of any special form of nuisance whose interests are involved in maintaining it, and who have their representatives or supporters in the House of Commons. But a tax upon size seems the most efficient and comprehensive weapon to use; it is quite impartial and treats all alike, and it reduces things to a simple and practical standard of definition. It might be very difficult to fix any standard of good or bad taste in regard to posters, and to admit some and refuse others; there would be endless differences of opinion on such a basis; but measurement of size is a plain fact about which there can be no dispute, and the result of fixing such a standard would be followed at once by an immense reduction in the number and size of advertisements, as it would not pay to indulge in them to anything like the present extent. It would probably be the only way of getting rid of the field-posters along the railways, as these are placed in numbers of different rural districts the authorities in which could never be brought to act in concert; whereas a tax, added to the rent already paid to the owners of the fields in which they are placed, would probably at once render them unremunerative.

Returning to the proposed amending Bill, we find the reasons stated for bringing it forward are that the wording of the principal Act left it too restricted in its operation. It authorised local authorities to make by-laws for restricting or preventing the exhibition of advertisements "in such places, and in such manner, or by such means, as to affect injuriously the amenities of a public park or pleasure promenade, or to disfigure the natural beauty of a landscape." This is evidently very limited in its application, or might be made so, as the reference to public parks

implies the exclusion of other parts of a town and its neighbourhood from the provision, and the mention of "natural beauty" in a landscape implies the exclusion of any landscape which might be held not to be beautiful. The amending Bill provides in Clause 2 that the exhibition of all advertisements "on land or buildings" shall be subject to regulations, and that powers may be taken to prohibit "the exhibition of advertisements upon any land which do not relate thereto, or to the occupier thereof, or to something done or to be done thereon or in relation thereto." That clause would get rid of the advertisement boards along the railway routes (which is probably what was in the minds of the framers of the Bill), if all the local authorities were to act upon it; but will they, or any of them, do so? The whole legislation, as proposed so far, is after all only permissive; it merely gives power to local authorities to make such regulations if they choose; and unfortunately local authorities are for the most part very difficult to move in such matters. It may be the only form in which there is a chance of obtaining legislation at present. But a tax imposed by Government would have been far more widely and certainly effective.

*The L.C.C. Draft Regulations for Reinforced Concrete.**

THE London County Council, under their General Powers Act of 1909, Clause 23, were authorised to formulate Regulations with respect to buildings wholly or partly of reinforced concrete.

The subject has been considered by a Joint-Committee representing the Council, the Surveyors' Institution, the Royal Institute of British Architects, and the Concrete Institute. Draft regulations have been drawn up as a result of their investigations, and notice has been given by the Council of their intention to apply to the Local Government Board for the necessary confirmation.

As it is only through the enterprise of the technical Press that any intimation was given to those chiefly interested of the existence of draft regulations, it would appear to be essential that the opinions of builders and professional men with regard to them should be obtained with as little delay as possible.

The Regulations, which consist of no fewer than 160 clauses, have evidently been drawn up with considerable care, and reflect no small credit upon everyone concerned; but, even with the utmost care in drafting, it is obviously a matter of great difficulty to frame long detailed regulations intended to cover a large field of new work in the precise words which will best avoid expensive and troublesome differences of opinion between those who have to administer the Act and those who desire to use this method of construction with due regard to safety and economy.

It is worthy of note that in America, where practical experience in reinforced concrete is much more extensive than in England, the latest Regulations for New York (published in this Journal of February 28th, 1912) are much more brief, and leave the authorities far more latitude for new developments in theory and practice than is the case with the proposed regulations for London.

It has been suggested that the new Regulations attempt to usurp the functions of a theoretical text book. No reasonable objection can, however, be taken to their stating the theoretical considerations with regard to which the stipulated limiting stresses have been fixed; and this they do with admirable clearness and brevity. But any such theoretical statements should be complete; they should not preclude other methods of calculation, and they should most decidedly be subject to automatic periodical revision. It is inconceivable that the last word can possibly have been said upon the theory of a subject of which barely one professional man in ten is acquainted with even the principal formulæ. In fact, a leading English text book even expresses strong doubts as to whether the *whole* of our present theory may not be based upon wrong lines. However that may be, the notes on the subject which have been contributed by Mr. Percy Waldram, and will be found in another

part of the present issue, seem to us to be worthy of the most earnest attention of all who are directly or indirectly concerned, and especially of those who are charged with the duty of rendering the proposed regulations as perfect as the present state of knowledge will permit. To this end Mr. Waldram's notes will no doubt be welcomed as a valuable and an important contribution.

The Society of Architects.

THE circular which has been issued by the President of the Society of Architects to its members, and which we presume to a good many architects outside its ranks (for it includes a paragraph inviting all those in favour of Registration to join), tends to confirm our opinion that the scheme of amalgamation with the Institute is not likely to be renewed; there is evidently no expectation of it; and the Society seems desirous to return to the *status quo*, as the only Society which has made Registration its principal aim. The insinuation that too little was promised to the Society in return for what it was to concede is rather absurd. The concessions which the Institute Council were prepared to make to the Society in case of amalgamation were, in regard to some points, almost preposterous, considering the relative position and history of the two bodies, and were evidently so regarded by the general meeting to which they were referred. The policy of the Society, as implied in the last paragraph of the President's circular, seems to be rather in the nature of telling all those architects who are in favour of Registration that "Codlin's the friend, not Short"; that if they really desire Registration, let them at once join the Society which has always made Registration its main object. This situation becomes rather humorous.

A Protest Against Official Architecture.

THE Glasgow Institute of Architects, through their spokesman, Mr. A. N. Paterson, A.R.S.A., made last week a very timely and moderately worded protest against the proposal to place the extension of the Municipal Buildings in the hands of the City Engineer. That they made the protest to some extent in their own interests, admitted was true; but they also made them mainly in the interests of the community. It might be taken for granted that it was both the duty and the desire of every member of the Council to secure the best results from the expenditure of public money on its buildings, and that it could hardly be the case if such work as this were entrusted to the City Engineer, who was necessarily much engrossed in administrative work. Other reasons might have been added against the employment of an engineer on purely architectural work; reasons probably in the mind of the speaker, but which it was thought better not to insist on. Mr. Paterson also pointed out, what is undeniably true, that it was a manifest hardship to the architects of Glasgow who paid rates and were therefore contributing to the upkeep of the City Engineer's department, that they should find this departmental officer turned into a favourable competitor. We will add another argument which might have been adduced, but was not. The Glasgow Municipal Building is the chief executed work of an eminent architect, the late Mr. William Young, who was subsequently appointed architect for the War Office, but died before the building was fairly commenced. There can be no doubt that Mr. Young would have had the strongest objection to the building being put into the hands of the City Engineer for extension; it is work for which an architect is needed. This practice of putting municipal architecture into the hands of officials, instead of employing the best architectural talent available, is on the increase, and ought to be strongly protested against. We are glad to observe that the local Press appears to have entirely supported the architects, the "Glasgow Herald" remarking that there were few cities in which such a proposal as that of the Town Council would be seriously entertained, even if it were made. We fear that is hardly the case, but we are glad to read so strong an expression of opinion on the subject in an important daily paper.

*See "Architects' and Builders' Journal," December 6th, 13th, and 27th, 1911.

On What is Wanted in Houses.

THE last issue of the Institute "Journal" gives a considerable portion of the paper recently read by Mr. Percival M. Fraser before the Institute of Sanitary Engineers, on "The Modern House." It appears that Mr. Fraser had asked a number of distinguished men and women to send him answers to the following questions: (1) "What has struck you as the worst point about an average house?" and (2) "What is the greatest improvement you have met with in building or in the fittings?" We are not given any list of the "distinguished men and women" to whom the questions were sent, but we are given the names of some of those who replied. They are nearly all novelists or dramatists. We do not know that the opinions of eminent novelists are of more value on such a subject than those of any other class of men who have attained distinction, but there seems to be an idea in the minds of many men that if an author has obtained celebrity in a literary sense, his opinion on every subject must be worth having; a position which the authors themselves for the most part fully endorse; the courageous manner in which novelists will pronounce (through the mouths of their characters) the most positive opinions on questions of art of which they evidently know little or nothing is often rather amusing.

A list is given by Mr. Fraser of the things objected to in connection with the "average house"—the "worst points" which these literary critics discover in it. The first is, "The large hall for a small house, being unsuited to English requirements"; why unsuited we are not told, but it is rather an odd coincidence that the large hall has just been recommended in a paper read at the Architectural Association, as affording a kind of general sitting-room or neutral ground for gentlemen and ladies. We should have said that a large hall is just the arrangement to give a little dignity and an effect of spaciousness to a small house, and that there is, in fact, everything in its favour and nothing against it. Another of the objections was to "sliding sashes" instead of casement windows. It would be interesting to know what was the reason for objecting to them. The sliding sash is really, for a cold country, the most convenient of all forms of window; the reasonable objection to it is the necessity for casings and pulley-weights, whereas the casement window can be fixed in solid frames. "Cupboard accommodation always inadequate" is an objection only too well founded. Many are the opportunities for this which are neglected in the average house. "No proper accommodation in rooms for furniture" is another reasonable objection; and so is "windows too small and used without discrimination." As we have before pointed out, the present popular idea of the picturesque house almost always means small windows, which may look very nice from the outside, but are not in accordance with the best hygienic conditions. "Basements, a great evil," is true, but they are unavoidable in closely packed town houses.

Coming to the answers to the second question—What are the best improvements noticed?—we find first "a bath and lavatory basin directly available from each bedroom." That is a counsel of perfection, certainly rarely met with in the average English house; it would be found in many good modern French houses, but the French house rarely provides so many bed-rooms as would be found in an English house of the same general dimensions, the French not regarding large families as a probable or desirable condition of life. A washing recess out of a bed room, tile-floored and provided with a bath, is a most desirable addition which is sometimes, but not often, to be found. English house-planning certainly needs improvement in this respect; and one thing which is seldom provided, but ought always to be, is a special bath-room for the servants of the house. The employment of double walls, affording even temperature, is a doubtful good; it means hollow spaces that can never be got at and examined. "The centralisation of the heating system" is certainly desirable. One correspondent notes with satisfaction "the great development in tin, light, cheap, and sound-proof partitioning"; whether it is always as sound-proof as might be wished is a question,

but there is no doubt that there have been of late years great improvements in the construction of partition walling. Another improvement that is noted is "the designing of details to avoid lodgment of dust"; a line of improvement to which attention was probably first drawn by the importance attached to it in hospital construction. It has a special importance there; but what is hygienic for hospitals is also hygienic for dwelling-houses, especially in towns, where dust is created and accumulates so much faster than in the country, and is of a more deleterious description.

One point which Mr. Fraser made in the course of his paper is worth special mention in these days of attempts at cheap cottages: "Nine-inch brick walls are quite inadequate in this country, except when built of sound bricks in cement and plastered with cement plaster on the outside or tiled." That points to one objection to the cheap garden city architecture of the day. It is the paradise of the nine-inch brick wall, which cannot be really accepted as the solution of the problem of economy, though we are inclined to think that even that is better than the "Spectator's" tarred timber.

Smoke Abatement.

AT the Smoke Abatement Conference last week, Sir Arthur Church appears, if he is correctly reported, to have summed up rather against the idea that smoke is the chief cause of the decay of stone in London buildings. He is reported to have said that it was not the carbon in smoke that did the mischief to building stones and mural paintings, but the sulphur compounds in the air which were absorbed by the carbon; and that the abatement of the smoke nuisance, or even its entire abolition, would not get rid of the injury and pollution caused by sulphuric acid. But if sulphuric acid has an affinity for carbon and is absorbed by it, surely in that case the smoke deposit is at all events the indirect cause of the decay of stone in London. Otherwise, why is it that stone that will, and does, last well in the country, will not last in London? It is satisfactory to be able to conclude, from the reports of other speeches, that those specially interested in London smoke abatement seem to have at last got rid of the fallacy that London fogs are due to the smoke. We used to have this continually dinned into us, in face of the fact that while there is a yellow fog in London, coloured by the smoke, you may find a white fog, quite as thick and impenetrable, just outside London. London fogs are due to the position of the city in the Thames Valley; the smoke makes them heavier and more disagreeable; it does not create them. Whether a thick London fog should remain a white fog, or should be thickened and rendered acrid by smoke deposit, seems to depend on the state of atmospheric equilibrium at the time, which decides whether smoke particles should be precipitated or not; it is a question of barometric pressure. Some of the thickest and most impenetrable fogs that have visited London within our recollection have had no evidence of smoke in them at all. That the greatest agent in the production of London smoke is the domestic fire is probably quite true, but it is not proved, as one speaker said, by the fact that the darkest fogs had been on Sundays and Christmas Days. We doubt the fact, in the first place; one of the worst fogs we remember was on a Christmas Day, but there have been as bad ones on other days, and in any case it may be doubted whether there are more fires in London on Sundays; on the contrary, there are likely to be considerably fewer; many people are out of town on Sundays, and the factories and workshops are not working; so that the argument seems fallacious. The increased use of gas both for warming and cooking is no doubt to some extent lessening the amount of smoke, and will probably do so to a greater extent in future, as the use of gas, for cooking especially, is on the increase. It cannot be denied, however, that a fire is the pleasantest way of warming a dwelling-room; there are many who will always prefer it; only legislation would put it down; and we are not likely to come to that. Grates designed to ensure a plentiful supply of air to the inside of a fire are the best preventives of smoke; for smoke really means imperfect combustion.

ARCHITECTS OF THE DAY.

MESSRS. WARWICK AND HALL, A.A.R.I.B.A.

THE opportunities which the open competition system affords to the young man in architecture are well shown in the case of Messrs. Warwick and Hall. This partnership comprises Mr. Septimus Warwick and Mr. Herbert Austen Hall, who have already carried out several important buildings as the outcome of public competitions, though they are both only thirty years of age. Before proceeding to deal with their work, a few biographical particulars may be given.

Mr. Warwick's architectural career commenced in the latter part of 1895, when he entered the office of Mr. Arthur Vernon, with whom he stayed for three years. Subsequently he was with Mr. George Walton and with Mr. R. S. Balfour, and when the latter joined with Mr. W. A. Pite he was head assistant in their office. Mr. Warwick was afterwards with Mr. R. Frank Atkinson for two years, during which time he worked on Waring's premises in Oxford Street and the Bromley Town Hall.

Mr. Hall, who is a nephew of the late Rev. Newman Hall, D.D., LL.D., commenced his training in 1897 with Mr. Philip Tree, of St. Leonards, with whom he stayed four years. He then went to Messrs. Silcock and Reay, of Bath, and later was under Mr. W. E. Riley, in the Architect's Department of the London County Council.

Mr. Warwick was elected a member of the Council of the Royal Institute of British Architects last year, and Mr. Hall has been a member of the Council of the Architectural Association since 1909, and was last year made honorary secretary.

They are both thorough believers in the competition system, though they think that there should be some modification in the customary manner in which competitions are conducted—more particularly they consider that there should always be a preliminary competition with sketch designs, involving the minimum amount of drawing, and that the architects thus selected to compete in a final competition should each receive a satisfactory honorarium.

It is frequently urged against competitions that they involve the loss of a great amount of energy and time, there being so many architects competing for a building which only one can get. Taking this view, some persons have endeavoured to work out the loss in actual figures,

CARVED SHIELD ON EAST ELEVATION.

and have thus stated a total sum of money and hours in order to prove the iniquity of the competition system. With these views Messrs. Warwick and Hall entirely disagree. They are of opinion that architects undertake a competition as, in a sense, a speculation, and they do so only when their time is not fully occupied by actual commissions in hand. From the business point of view it is urged that, competition or not, the standing charges of conducting an office are just the same, while the possibility of reward—in the shape perhaps of a good-size building—well merits the time and labour involved in the attempt to secure it. Messrs. Warwick and Hall feel quite satisfied with this view as applied to their own case, and

S. WARWICK, A.R.I.B.A.

H. A. HALL, A.R.I.B.A.

COMPETITION DESIGN FOR THE MANCHESTER LIBRARY AND ART GALLERY. WARWICK AND HALL, A.A.R.I.B.A., ARCHITECTS.

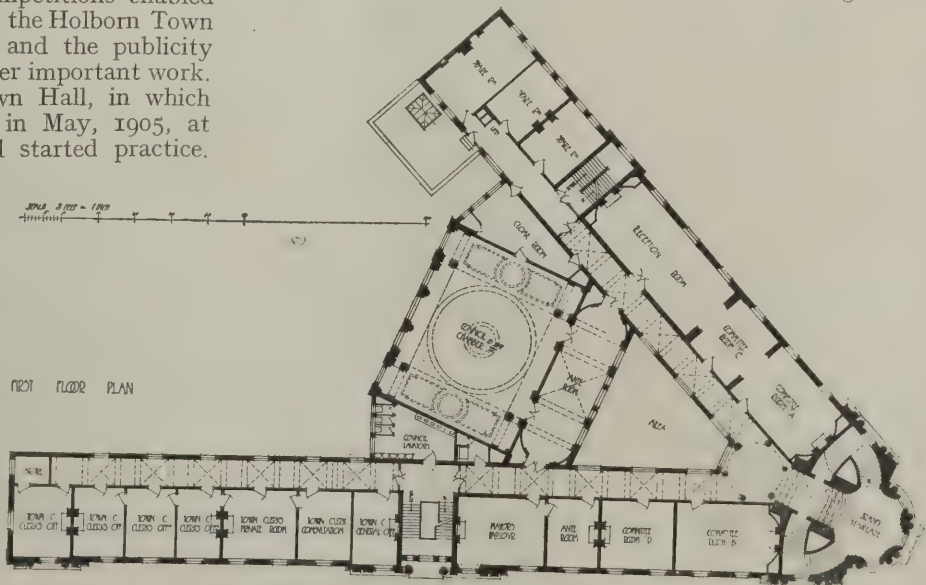

LAMBETH TOWN HALL: WARWICK AND HALL, A.A.R.I.B.A., ARCHITECTS.

the reason that they make all their own drawings; and as competitions to them are a pleasant exercise, done generally after the ordinary office hours, they enter upon the work with an undisturbed mind.

Undoubtedly, as stated at the commencement of this article, the competition system does offer the young man a chance which he would never otherwise get. There are plenty of modern instances of this, the two most prominent being Mr. Ralph Knott with the London County Hall and Mr. G. Gilbert Scott with Liverpool Cathedral. In the case of Messrs. Warwick and Hall, competitions enabled them to build the Lambeth Town Hall, the Holborn Town Hall, and the Berkshire County Hall, and the publicity thus secured has provided them with other important work. The competition for the Lambeth Town Hall, in which there were 114 competitors, was won in May, 1905, at which time Messrs. Warwick and Hall started practice.

It was completed in 1908, and the architects had the signal honour of having their first building opened by the present King and Queen, who were then Prince and Princess of Wales. In 1906 they were invited to take part in the limited competition for the Holborn Town Hall, which they won, and in 1909 they were the successful architects for the Berkshire County Hall (for which there were 177 competitors). They have also received premiums in competitions for town halls at Bury St. Edmunds, Burslem, Ilkley, Truro (Cornwall County Hall), Sutton Coldfield, Stoke-on-Trent, and Marylebone, and they were selected to take part in the

final competitions for the London County Hall and the Manchester Library and Art Gallery—which is, we think, a remarkable record for two young men. A large group of workmen's flats at Hackney was completed from their designs last year, and at the present time there is being erected from their designs at Perth, Western Australia, a fine office building for Messrs. Millars' Karri and Jarrah Wood Company. In addition to work of a public character, they have carried out a certain amount of domestic work, including houses at Romford, Bray, and Tunbridge Wells.

LAMBETH TOWN HALL: FIRST-FLOOR PLAN.

(the last-named for the Marquess of Abergavenny, K.G.), and alterations to "Killyon Manor," Co. Meath; 46, Sussex Square, Brighton; "River Mead," Rickmansworth; and "South Home," Chislehurst. They have also considerably enlarged a factory at Harpenden for Almagam, Ltd.

Some detailed particulars of the public buildings that have been erected from their designs are given below.

LAMBETH TOWN HALL.

This building occupies a triangular site at the corner of Brixton Hill and Acre Lane, S.W., the length of the principal façade (to Brixton Hill) being 274 ft., and the return elevation 200 ft. The building is so arranged on the site as to use the angle to advantage, leaving the greatest possible amount of space at the rear for future extension. The principal entrance and grand staircase are planned at the corner, and the rates office on the ground floor, with the council chamber above, are arranged on the central axis of the building. The principal entrance opens into a large circular vestibule immediately adjoining the grand staircase, at which point corridors branch off right and left to the borough engineer's and borough accountant's departments. The rates office, which is the principal room on the ground floor, has two separate entrances from the street, which entrances also serve the rates appeal room in the basement.

From the vestibule the grand staircase rises in two sweeps to a circular hall, whence it continues in one flight to the first floor. The walls of the circular hall are treated with plaster decoration, and the floor is paved with black, white, and green marble. Leading off the corridors on the first floor are the town clerk's department, the medical officer's rooms, mayor's parlour, committee rooms, and reception room. The council chamber, including the galleries, is 72 ft. by 40 ft., and has a dome 30 ft. in diameter. On the west side are five windows enclosed by Ionic columns and pilasters, and to assist the general lighting a lantern is provided in the centre of the dome. The dome is constructed of reinforced concrete, decorated inside with fibrous plasterwork and rendered outside with asphalt.

The elevations are carried out in Portland stone and narrow red bricks with wide joints, the base of the building being of grey granite, and the roofs covered with green slates. The tower, designed to accentuate the main entrance, is 134 ft. high, and has groups of sculpture on the four corners representing Art, Literature, Science, and Justice.

THE BERKSHIRE COUNTY HALL.

This building has been erected in the Forbury at Reading, adjoining the Assize Courts. It was opened in March, 1911. In its arrangement, particular attention has

been given to the planning so that members of the council can have direct communication from the hall of the Assize Courts, as well as from the front entrance of the new building. The committee rooms have been placed at the back of the building on the ground and first floors, so as to ensure privacy and quietness, in a position where they are easily accessible from the main staircase and lift. The main staircase (with passenger lift) is planned so that it will be equally convenient of access from the main entrance of the new building and from the Assize Courts, and is so placed that it serves each department centrally on the upper floors. The ground floor provides accommodation for the clerk of the peace and his department, the education secretary being placed on the first floor. The second floor is devoted to the county treasurer's department, land steward, and medical officer, and the third floor is utilised for the surveyor's department.

In the committee room on the ground floor there is some interesting woodwork, including a chimneypiece inlaid with a geometrical pattern in the centre panel and having on either side pilaster strips crowned by cherubs' heads.

LAMBETH TOWN HALL: MAIN ENTRANCE.

ST. GEORGE'S HOUSE, PERTH, WESTERN AUSTRALIA. WARWICK AND HALL, A.A.R.I.B.A., ARCHITECTS.

The elevations are treated in a broad simple manner, relying upon the general proportions for effect rather than the use of elaboration of ornament. They are carried out in red brick (five courses to the foot) with Portland stone dressings. The roofs are covered with specially made tiles on the Italian principle.

HOLBORN TOWN HALL.

This building adjoins the Holborn Public Library, with which the new portion had to harmonise externally so as to secure uniformity of appearance. For the accompanying two views we are indebted to "The Modern Building Record." Each floor has a large circular hall adjoining the main staircase and lift. The council chamber is on the second floor in a quiet position, and on the same level are the committee rooms, mayor's parlour, and ante-room. Immediately under the council chamber is the court room, in which the magistrates hear licensing and other business, and where rating assessments are conducted. The remainder of the building is occupied by the borough officials, whose departments are all self-contained.

SYLVESTER HOUSE.

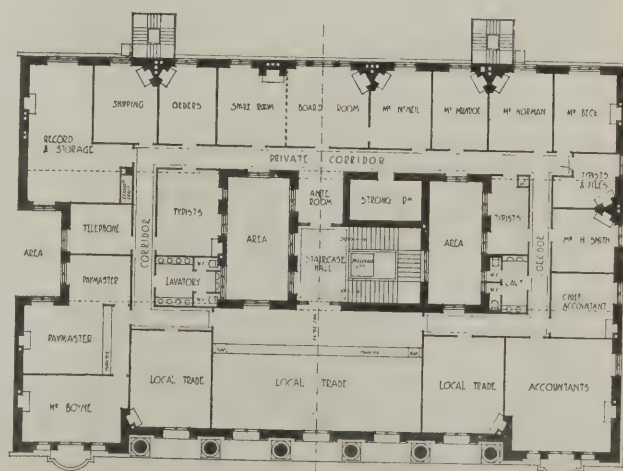

Sylvester House is a group of working-class flats which have been erected in Sylvester Road, Hackney, through the enterprise of Sir Richard Stapley and his partners, who have considerable interests in Hackney, and are keenly interested in housing matters. The building consists of four blocks, with a central garden for the use of the tenants, as shown by the photograph on page 349, the special aim having been to make the rooms as bright and sunny as possible. The dwellings provide accommoda-

tion for 80 families in tenements of two and three rooms; the rents varying from 6s. to 10s. weekly, according to situation.

ST. GEORGE'S HOUSE, PERTH, WESTERN AUSTRALIA.

The increasing prosperity of Western Australia is nowhere more marked than in the capital, Perth, which is rapidly being transformed from a comparatively small town into an

important city. Among the many notable buildings in course of construction at the present time is St. George's House, which is being erected for Millars' Karri and Jarrah Company (1902), Limited, the well-known sawmill owners, who are the largest exporters of jarrah from the forests of Western Australia. The site of the building is in St. George's Terrace, the principal business thoroughfare of the city, containing most of the Government offices and leading at its western end to the Parliament House. St. George's House is being carried out externally in stone.

Internally the construction is entirely fire-resisting, and suites of offices are planned throughout the structure on the most up-to-date lines. The building is being carried out from Messrs. Warwick and Hall's drawings under the supervision of Messrs. Hobbs, Smith and Forbes, architects, of Perth. The perspective view on the preceding page we are able to give by courtesy of "Academy Architecture." In connection with it the $\frac{1}{2}$ in. detail on pages 356—357 may well be studied, as a good example of modern work.

PATRIOTISM IN ARCHITECTURE.*

BY C. F. A. VOYSEY AND ARTHUR KEEN, F.R.I.B.A.

Mr. Voysey's almost passionate appeal for less imitativeness, and a greater regard for first principles, was perhaps somewhat marred by excess of fervour in the expression. It was nevertheless of very definite value as a stimulus to thought, as Mr. Arthur Keen very gracefully acknowledged in his trenchant reply.

MR. VOYSEY'S PAPER.

THE present age shows a strong tendency to swing towards the development of our imitative faculty, leading to conformity and collectivism, and away from the individual, creative, and idealistic manner. In this collectivist attitude we see a vast amount of deadly conventionalism, which is a form of tyranny oppressing the young and old alike.

A Definite Order.

A desperate endeavour is now being made to dominate men's conduct and to create what its advocates call a "national style," by imposing a definite Order of architecture on the young, and likewise upon the unfortunate competitor for public buildings.

Our educational system is based on the assumption that some foreign architecture is a fit study for an English student. And he is given every encouragement to travel in foreign lands, and by such means to gain fluency in the language of architectural forms without the laborious study of the national character and conditions that have given them birth. It cannot be denied that it is far more important to know from what general principles good work is produced than to have a knowledge only fitted to reproduce given examples.

Faithful Use of Local Materials.

Now we must observe that in all the finest examples of architecture throughout the world we find that the qualities we admire are due to the faithful use of local materials and conditions, the sincere expression of national character and aspirations: both of which qualities are strongly influenced by climatic and also geological and geographical local character. The climate of a country affects the light, and the light affects our enjoyment of textures and colours quite as much as of light and shade. Let us mark well this characteristic of the finest architecture—namely, that it grew mainly out of national conditions and national character, and was never a foreign importation. And a national style can grow up in no other way. We must recognise our conditions, material and intellectual, if we would obey the Divine law of fitness.

The Law of Fitness.

Are we working now on this principle? Are we not setting up a model drawn from foreign lands, and endeavouring to squeeze our requirements into it?

Having deprecated the holding up to admiration "American railway-stations designed closely on the model of ancient Roman baths," the author said: What wonder if ignorant people buy old barns and convert them into houses, forgetting that if they are good barns they must be bad houses, and if good houses very bad barns! As if good architecture were not the direct product of the purpose of the building. The general custom is to set the heart on a symmetrical façade and then squeeze our plan into it, making dark passages and lobbies, rather than

upset our symmetry. Do we not often use draughty, rattling wood sashes instead of stone windows and iron casements, in order to produce a Renaissance character in our building? Do we not give the same size window to a closet that we give to a banqueting hall if it happens to come on our main front? How often do we see puny little villas aping the manners of a ducal palace, porticoes and empty niches, cornices and broken pediments provided for the villa rented at £70 or £80 per annum! Showing clearly that the outside comes first in our calculations and the plan afterwards, and that we are wedded to a form that is not born of the parent of practical requirements, but the foster-child of a foreign-bred fancy. The structure is designed from without inwards, not, as it should be, from within outwards. I will not plead for either Gothic or Classic, but only that conditions and requirements shall dominate inside and out, and, above all, that the expression of thought and feeling shall be national and sincere. We do not want Chinese national character expressed in Piccadilly any more than Grecian or Italian character. We do not want the poor man's villa to ape the stately home of the wealthy.

The more we go to Rome, the less we shall know of London. The freshness and charm of foreign lands has belittled our reverence for our own country. And we are apt to forget that we have a climate and country different from all other nations. We cannot ignore this fact without loss of patriotism and national dignity.

Possibilities and Limitations.

Fitness is a Divine law, and the more we investigate Nature the more we become impressed by its fitness: therefore we do wisely to work on the same lines and strive diligently after fitness. Can it, then, be fit to use foreign styles to express English thought and feeling? The English architect down to the end of the Tudor period was content to learn and understand all the conditions of his own country, to understand the character of his own countrymen and to express their emotions and aspirations. He was keen to learn the possibilities and limitations of his material, and, in order that we may benefit by his experience in this direction, we should study all the pure English examples we come across, never forgetting that it is only unalterable technical qualities which we most need to learn, and not those accidents of passing fashion, or the changing manners and customs of different periods. It is very important that we should notice, for instance, the way the stone in different districts was used, rather than the existence of battlements or moats, which tell not of the history of building so much as of the manner of life of the people.

In our admiration for ancient examples we are apt to imitate the forms of obsolete features and miss the practical and essential truths concerning the fitting use of material. This disregard of national character and national needs and conditions is the foundation of nearly all our unpatriotic conduct and sentiment.

Un-English Architecture.

But, alas! the later Englishman has been unfaithful; he has turned his back on his own climate, and hardly speaks of it except to abuse it! And he has opened his arms to all the foreign material he can lay his hands on. And he raves about the most un-English architecture he has got, regarding it as so magnificent that all practical considerations must be waived for the purpose of providing an aesthetic approach to it.

The fact that our St. Paul's is well proportioned and gives us a pleasing sense of light and shade, and is big, justifies its existence in many people's eyes. But that it is a clever man's copy of a foreigner's expression of his own national character—albeit a foreigner's wise and clever use of his own conditions and requirements—never seems to be considered as in any way a proof that St. Paul's is an exotic and not a national growth. It is not the product of our climate or the outcome of our national life. It is a theatrical falsehood of the most prolific period of profligacy. The few wealthy who could afford to travel were intoxicated by what they saw, and they quickly lost their hearts to foreign beauties. And the universal law that we strive to reproduce what we love and admire led them to tear down their English houses and erect Italian, Renaissance, French, and other foreign examples in imitation of what they had seen and in boastful proclamation of their foreign experiences. We are now gradually awakening to the consciousness that the ravishing beauties of foreign architecture are always due to their being true and noble expressions of national character, governed by reverent regard for local conditions and materials.

Artificial Modes of Expression.

It is of very great importance that we should get at the truth of this matter, because our present method of education and the practice of our profession is steadily leading to an artificial mode of expression independent of the practical necessities of life. Our town halls, banks, public and private houses are all stereotyped bastard children of foreign parentage. And there is an effort being made to coerce the shopkeepers into the same mould. No matter what their trade may be, they must manage their business as best they may behind the Renaissance shirt-front. As if true architecture were the expression of a cultured traveller, rather than a stay-at-home craftsman's endeavour to use local material fitly, to minister to individual needs and requirements.

The Town Planner.

The town-planner is a collectivist; his idea is to drill humanity into line and regulate his outward movements regardless of his inward needs. He, too, regards the general aspect and ignores individual necessities. He must have building lines and symmetry, regardless of individual tastes and requirements. He would have our tastes and requirements regulated by Act of Parliament—the deadliest machine ever invented when used to coerce taste.

The vista may be a fine model to emulate and a suitable place for strutting human peacocks and peahens, but for a strenuous practical Northern people it is not a fit and true expression of their needs to be introduced into every speculative suburb. The revival of any style or period of architecture, whether English or foreign in origin, is an evil which

*Extracts from papers read before the Architectural Association on March 25th.

tends to retard the due consideration of fitness in all its aspects.

Avoidance of Stereotyped Conventions.

If we start a plan for a house with any preconceived example of a Classic temple or a Georgian mansion, a Roman bath, or even a Gothic monastery, we shall be the less influenced by the peculiar characteristics of the site, the building owner, or the purpose of our building. And it is from the consideration of these conditions alone that all the finest architecture throughout the world has ever sprung. Moreover, consider how immensely stimulating it is to all human powers to have to evolve your building from such sources. The delight, too, of searching for moral qualities worthy to be stimulated by our building is untold, necessitating also an interest in contemporary life and feeling, so keeping our work alive and growing, and avoiding the stagnation of stereotyped conventions of ancient times. But the present method is to accept first a Renaissance conception and then ingeniously squeeze your accommodation into and behind the shell, and classify your requirements to suit your thirst for symmetry. It is like a Chinese puzzle, a *tour de force*, a clever exercise in cunning, leading to all manner of subterfuges, and as such demoralising to all concerned.

Why English Domestic Work Excels.

It is generally admitted that our English domestic architecture of recent years has advanced much more than the architecture of our public buildings and monuments. And I fearlessly assert it is because much of our domestic work has been produced by the method herein advocated, whereas our public buildings are invariably produced on the method condemned. And why? Mainly because the authorities who have to vote the money to pay for them are trying to please their electors, and they know that if they put up a hall-marked building—that is, something colourably like St. Paul's—no one will venture to criticise their choice on their taste. The word has gone round that St. Paul's is all right, and it has been repeated so often that Mr. Brown and Mr. Robinson find it a very convenient sample of good taste by which to gauge their public buildings. not one of them ever dreaming of the question—Is St. Paul's English? Is it a patriotic expression of our national character? If our modern public buildings are the outcome of foreign travel who can defend it? Surely they are the deadest, uninspiring piles of wasted labour and material that any country can show—successful as dirt-traps and dust-catchers, emphasising the grimy nature of our town atmosphere. Here, then, we surely find in the rustications of our wall surfaces clear proof that the desire to adapt foreign detail has outweighed all considerations of fitness to our dirty town atmosphere. Innumerable are the examples of similar conformity to foreign styles, preventing due consideration of practical fitness; durability and cleanliness are sacrificed to imitative convention. The true mathematical proportion and placing of the Orders is regarded as far more important than the adequate lighting or convenient placing of our chambers. We ought no more to teach the five Orders to students than to train them in Chinese. Many will say that without the five Orders no sense of proportion can be taught. I do not think that with any Orders you can teach proportion. Proportion is a matter of feeling dependent on general culture

and temperament. You may notice that every man's sense of proportion varies as much as the proportions of his body and limbs; and when he is sincere in the expression of his sense of proportion it is a reflection of his own bodily frame.

Teach Ethics, not Art.

We can very well teach the character of materials and their proper use and limitations, but the less we try to teach art the better. Teach ethics instead, and make men think, and art will take care of itself.

It would surprise many of us if we were to consider the amazing effect on modern architecture the one study of cleanliness would produce. If we are to avoid dirt-traps inside and out we must concentrate our ornament and produce breadth and simplicity, both of which qualities demand good material and good workmanship. So by omitting conventional Renaissance detail we should be driven to devote much thought and feeling to the enrichments we have, and in the plain broad surfaces we should feel the necessity of well-chosen, genuine material and a high quality of workmanship.

We can never arrive at these qualities if we are working to a definite style of the past. Use the past to supplement your experience of the use of materials, their possibilities and limitations, but do not be a slave to it. Do not depress young students by telling them they cannot possibly excel the noble men of old. Our increased experience ought to make us more able to excel anything that has gone before. The cultivation of patriotic feeling should make us devote more attention to English material, English conditions, and English character, and free us from the stigma of being called the most inartistic nation on the face of the globe.

Art, being the manifestation of human thought and feeling, must always be individual and national. Emancipation from the tyranny of styles would open the door to brother-craftsmen. We should feel the necessity for the work of the painter and sculptor in our buildings if we omitted the acres of machine-made Renaissance ornament. And brotherhood between the arts is what we need to stimulate, and it must necessarily follow the growth of patriotism in architecture.

Truthfulness, Fitness, Fidelity.

The strongest argument in favour of creating buildings from requirements and conditions, rather than in obedience to any preconceived style or mode of expression, is that it opens the way for the appeal to our higher nature, and stirs up the emotions and moral sentiments. It forces us to consider moral principles and work on definite lines of truthfulness, fitness, and fidelity. In our admiration for ancient buildings we forget that it is their manifestation of the spirit wherein they are great. The material we see is perishable and illusory. But in the spiritual significance and expression of moral sentiments they are indestructible.

Can we not emulate Shakespeare in our architecture, and by patriotic feeling express and encourage what is best in our national character?

MR. ARTHUR KEEN REPLIES.

Mr. Arthur Keen said: Let me say first how much Mr. Voysey's presence here this evening is appreciated by us. He has not hesitated before now to tell us frankly that he did not approve of our methods of education, but by coming to speak to us to-night he shows that he is moved by no

narrow or dogmatic spirit, but is anxious to help us in our study of the art for for which we share his affection. The position he takes up is a strong one, for although he perhaps will not admit it, his appeal is to our feelings rather than to our judgment; and he speaks with the seriousness of conviction because it is well known that to the extent of his opportunity he has carried into effect in his own practice the views that he holds of the possibilities and limitations of architectural art in the present day. But that he is right in his main contentions I cannot agree. If he had put them forward thirty years ago they would have been received with enthusiasm, for the spirit of the mediæval past had a strong hold on the architectural imagination at that time; but the Gothic Revival has passed. And what has it taught us? It has taught us that it had to fail because we are no longer Gothic; that the Gothic tradition ended long ago, and cannot be conjured back to infuse our work with the vitality and personal quality that belongs to the old, because our character and disposition have changed, our social conditions have altered, and our attitude towards all things has become one of doubt and enquiry in the place of submission and faith. Why should we live in a fool's paradise and imagine that things are other than they are? It never has been any use, and it never will be. We are eager and self-seeking, we have acquired education, we have travelled and seen the world; we have facilities for the interchange of ideas and commodities; our methods of life and industry, our political views, our very religion has altered—we are the products of an eager, ambitious civilisation, dominated by science, by competition, by individual liberty, and by aspirations, hopes, and ideals different from, and opposite to, those of the past.

A Broader Basis of Authority.

In many directions, however, there seems already to be a more general consensus of feeling, a broader basis of authority, a more definite conviction as to wide principles; and is not this coming about in the matter of art as in other things? Are we not already weary of each man doing that which is right in his own eyes, and is not the cry for a Ministry of Fine Arts the outcome of a desire for peace and good order, sobriety and restraint?

Convention, social restraint—call it what you will—is it possible, human nature being as it is, to get away from it for long? Man is a social animal, and is, and always has been, ruled by convention, by the general acceptance of right and proper usages. It is an inborn sense, and collectively he cannot get away from it. However much an individual here and there may kick against it, our architecture must be conventional if it is to represent us truly; and it should be of such an order that it can yield good results to a formal, academic method of expression that is able to associate itself with science and orderly civilisation, and with the commercial and social conditions that now obtain. An architecture that depended on the detached and original attitude of each individual would be intolerable. Wise restraint is almost always to be preferred to uncontrolled individualism. It the best days of architectural art and of the development of that art convention was universal—buildings, whether temples or churches, as much as ships and fortifications, were made on orthodox lines. Growth along

those lines, not departure from them, was the constant characteristic. Indeed, it is difficult to reconcile the design of a Greek temple with what one knows of the artistic aspirations of the Greeks, except on the principle of overmastering convention—a somewhat rude, ungainly type of building, impressive and dignified in its simplicity, but lacking the resource and imagination that we associate with Greek sculpture and decorative design.

Unity of Effort.

There certainly seems now to be a desire to impose a definite and generally recognised method of architectural treatment, because the struggle has gone on long enough, and we feel that in unity of effort lies our only hope of achieving in any worthy way a form of expression that can be considered national; so that by these forms and these methods shall those who follow us know that this was the work of the British nation in the twentieth century.

What is the logical outcome of the objection to sending the young man out to see the world? This, as well as the suggestion that he should work only in the material of his district, is the echo of the time when no facilities for travel or traffic existed. It would make the student into a kind of ancestral beaver, secure in his lodge, protected by his dam, snug and self-satisfied, without incentive or imagination or horizon. Are we not to take the world as it is, and are we to try and force our part of it back into a position it has left long since? I agree with Mr. Voysey that the revivals that he deprecates are lamentable enough, although in a measure they express faithfully the national attitude towards things; but I submit that the course we have had our attention directed to by him involves a greater revival than any we have had before a revival of former social conditions rather than one of mere architectural forms, and I think that to be successful it involves the architect in becoming a mason, or a sculptor or a carpenter again; for, if I understand aright the qualities that Mr. Voysey desires, they are to be obtained in no other way. We have had cases enough, and to weariness, of endeavours after texture and local character, and the appearance of "craftsman" art, obtained by laborious detailing and by close supervision of the workman, and I say, without hesitation, that such efforts are wrong artistically.

We are not Mediæval.

We have to produce our architecture at the drawing-board and by means of specifications and letters and bills of quantities; for Heaven's sake let us be honest and admit it, and not try to pretend that we are treading in the steps of our ancient brethren when we are beset about with contracts and by-laws, with county council applications, with party walls, and with all the appliances and products of science and commerce. I was shown recently on a lantern screen two pieces of brickwork—one a genuine piece of fifteenth century work with all the charm of irregularity and texture upon it and in it; the other was confidently put forward by the lecturer as the best bit of modern brickwork he had ever seen; it aped the characteristics of the old work in its irregularity, but to me it was a slovenly, untidy, rough bit of work that would have been a disgrace to the bricklayer if one had not known that the poor man, no longer free to work in the accepted way, had been made to do it, by the architect, as a deliberate piece of affectation. We are not mediæval bricklayers or masons; why

should we pretend that we are? I do not think that Mr. Voysey wishes us to do so, but I do submit that what he suggests to us really involves us in something of this kind, for he claims that architectural character is to grow again out of the nature of the material, and its right uses in order to meet the needs of the time and express the ideals of the individual; as I understand it, this is the mediæval attitude, and involves the mediæval method.

Was Our Work Ever National?

We are to make our work national again; but when was it ever national in the sense of excluding foreign influence? It has been in a constant state of change since the beginning of our civilisation, and I think it would not be difficult to show that most of the change has been due to foreign sources.

The Saxons came from over the sea; our Norman architecture was an importation; Westminster Abbey itself is on a French model. Mr. Lethaby has been making startling suggestions lately as to architectural beginnings, and the transfer of features and of methods of construction from one part of the world to another. And why should not this transference take place? Does the delightful little bridge at Prior Park fit less well into the English landscape because it is in a sense an exotic? Are not the bridges at Cambridge or Bath homely and natural, although they may be based on foreign models? It not Stamford a characteristic English town, although it is full of Palladian work? In every age and place the art of the native craftsman has been tinged and suffused with the foreign influence. Here in England it has proceeded side by side with that of the professional architect for many generations, "stealing and giving" charm.

The "sincere expression of national character and aspirations"—what is it? What does it mean in these days? And what does "Patriotism in Architecture" really mean? Does it really mean anything except that we are to use everything that comes to us in a reasonable way to suit our own particular needs?

Axial Treatment.

We need be under no misapprehension that a style of architecture that does not faithfully serve the national need will endure. Mr. Voysey is severe on our town halls and banks and railway stations, but to the extent that their architecture does not meet its requirements it already stands condemned. Is he not unduly severe with these buildings? He seems to deprecate symmetry in design, but surely a town hall is essentially a building that calls for such design; its plan must be simple and regular; the requirements of it suggest and impose uniformity and repetition. The axial treatment is the right one. And is not symmetry in the design of domestic buildings a great factor of beauty? Are such houses as Montacute and the great Jacobean mansions or the house in West Street, Chichester, the worse for it? I submit that house planning was never more sound and serviceable than today; but when have we had more striving after regularity and balance than at the present time?

The Law of Fitness.

Mr. Voysey says that a national style can only grow up by a recognition of our conditions, material and intellectual; that we must obey the Divine law of fitness. Nothing can be more true or better expressed; but this does not cut

us off from foreign influence; on the contrary, it leads us to it, for we are cosmopolitan in these days—not hide-bound, prejudiced islanders. No doubt an architect may be wrong if he makes his railway station resemble the Roman bath he has seen in his travels; but this is no argument against travel. He would be equally reprehensible if he made it resemble Durham Cathedral; but on the other hand, a fine sound conception like the front of King's Cross Station may be the direct outcome of something seen in Spain or Constantinople.

I think it is a fair claim that most architectural students are, as a matter of fact, being taught to recognise all material and intellectual conditions, and to observe particularly the supreme law of fitness. But it is on this point that the issue really depends, for the schools advocate the use of certain well-known architectural forms and features in design that is to comply with these principles, and Mr. Voysey claims that these forms and features are not admissible; that they have no connection with reasonable design, and that in fact they are used for their own sake. I think he is right here to a very great extent, and that features are commonly used in a wrong and gratuitous way; but surely features of some sort are admissible, and why should not suitable ones be adopted from old work, either native or foreign?

I fully agree that we must master, as far as we can, as Mr. Voysey says, the unalterable technical qualities, the uses and character of materials, and the essential truths relating to their handling; but, as we have been told before now, this leads as only to "pleasant building"; it is but a small part of architecture. Indeed, is it architecture at all? Is not architecture something added to building, something expressed through building, but in no way essential to it?

Past and Present.

We have been told that our present methods of education are steadily leading to an artificial mode of expression, independent of the practical necessities of life. Now, I doubt this very much. I believe our education is endeavouring to keep step with other education, and to equip the student to meet what must be regarded as the practical necessities of modern life. I do not want to be misunderstood or to put myself in a false position. I admire and love the old things; I would rather go out of my way than let an old bridge or a Whitgift Hospital be pulled down; I would look through wavy old glass rather than have it replaced by plate; but the methods and the ways of life that produced them belong to the time that is gone for ever, and can no more be called back than the Psalms of David can be written again.

I think Mr. Voysey is quite sound when comparing the past with the present. It is too true that, while we have gained knowledge, we have lost insight; we have got experience, but lost imagination; good taste is no longer spontaneous; the unerring instinct and judgment of the craftsman are gone, and we can no more work with the methods of the past than we can regain the blind unreasoning faith of our Calvinistic forefathers.

There are all sorts of questions about durability and cleanliness and colour on which I should have liked to join issue with Mr. Voysey if there had been time; let me merely interject here that in places where smoke and soot predominate, the rougher and not the smoother a building is the better; for even soot will reflect light if it is in irregular lumps, but not

when it is a smooth greasy skin over a polished marble or smooth ashlar surface.

Sound and Scholarly Design.

It is to the main characteristics of sound and scholarly design that we must look in these days, not to the touch of the craftsman. To breadth and proportion, to light and shade, to balance and composition and contrast, to sound and obvious construction, to fitness, to beauty of detail, to cheerfulness and light. We are not German, or Italian, or American, or French, and everything will be done in our own English way; if we are all soundly taught, and taught on similar lines, our architecture will be worthy and dignified, free from vulgarity or untruth, and we need not fear that it will not be national. But to begin the whole thing anew and invent our architecture again or evolve it anew out of methods of building, while turning our backs on what the past has to offer, merely because it may not be of English origin, seems to me to be to invite disaster and chaos;

just as wrong as to destroy all our pictures and to learn painting again.

Mr. Voysey's High Ideals.

But let me conclude as I began, by expressing appreciation of the service Mr. Voysey has rendered to us by what he has been saying. He has initiated the discussion of a matter of great interest. He has condemned all that is mean or vulgar, sordid or dishonest; he has held up to us an ideal of the highest kind—an ideal that I believe myself to be incapable of realisation by reason of the conditions that now control us, but an ideal that he has put forward with sincerity and conviction; an ideal that we may always keep before us to correct our judgment, to form our character, and improve our aims. If we do not perhaps see eye to eye with him in the method of its attainment, we all share his hope that the architecture of our future shall be noble, pure, and inspired, worthy of its past, and in the highest sense national and expressive of national aspirations.

DISCUSSION.

Mr. Harrison Townsend, seconding the vote of thanks, asked whether Mr. Voysey's paper would not have been improved by a definition of patriotism. The dictionary sense was: "One whose ruling passion is the love of his country"; but a patriot, although a lover of his country, was not necessarily the neglecter of another country. Johnson, in one of his essays, said: "That man is little to be envied who would not gain force upon the Plain of Marathon." There was a wider patriotism which did not exclude other countries, but hoped to gain by their teachings. If architecture was to be confined to a country, why not make it parochial and limit it to districts? Mr. Voysey, he continued, could not have put a worse witness in the box than Shakespeare. Shakespeare wrote thirty-nine plays, not one of which dealt with an English subject. He went to Italy, Greece, and Rome, and transmuted their thought into English thought; and in the same way an architect would not be less an Englishman, but rather more an Englishman, by having a wider and more fully charged mind.

Mr. Arthur T. Bolton said it would be well to remember what an enormous influence Mr. Voysey's work had had upon other people. Much as he admired his (Mr. Voysey's) buildings, however, he could not accept his gospel. That men were doing work in the Middle Ages without caring for what had gone before, as Mr. Voysey seemed to believe, was, he thought, historically untrue. He seriously believed that those who had travelled most found out the local attitude in a country; and when they returned they were better able to discover what the local character was at home. With regard to climate, Mr. Bolton took France as an example, where the range was enormous; and in different parts of England climate was subject to immense variations. It was impossible to classify the climate of a country, as Mr. Voysey would do, for this reason. When, he continued, one honestly tried to design a building which merely met the needs of the case, people would say it was dull, and that they wanted something more. The arcades, for instance, in Romanesque and mediæval cathedrals did not arise out of the construction, but were put there simply because people liked them. It was the same with the Orders; if they were liked, there was some human necessity for them. St. Paul's Cathedral, it should be remembered, derived its plan from Ely. Wren was a remarkable man who had a knowledge of Gothic for which he was not generally credited; and he thought that in St. Paul's they had a clever interpretation of English ideals with Renaissance details. There was nothing like St. Paul's; which, in its way, was a very English design. With regard to the Orders, the reason they were retained was because they taught the student a great deal about proportion. By studying them, the student gained the sense of designing detail in accordance with a certain standard. As to teaching ethics in relation to architecture, where Ruskin had failed he did not think we should do much good.

Mr. Allan Potter said he had a great deal of sympathy with Mr. Voysey in his objection to foreign travel when it only resulted in the production here of some contemporary foreign style. With respect to the Orders, surely they should be taught as Latin and Greek were taught in schools. Latin was not taught so that a student should write dog Latin,

EGYPT AND GREECE. DRAWN BY A. C. CONRADE

but that he should be able to write good English. We did not want merely to copy the buildings of the past. Because Westminster Abbey and St. Paul's were suitable to the periods at which they were built, they were not necessarily suited to the needs of the day.

Mr. H. W. Brittan suggested that it was really the spirit of the times to which Mr. Voysey objected.

Mr. A. E. Bullock said that Mr. Voysey objected to the Classic style and sash-windows because we had abandoned our old love. Nevertheless, we had gained thereby our Georgian style—a style as lasting as any other.

Mr. C. G. Boutcher and Mr. Alex. Smithers having spoken, Mr. Gerald Horsley, in putting the vote of thanks, said that Mr. Voysey, in the expression of his strong individuality, had quite overridden the facts of history. What they had learnt from Mr. Voysey was the very high ideal he had put before them.

Mr. Voysey, in reply, said he was surprised at the amount of courtesy he had received. They had been shooting all round him, but he felt not the least bit killed. The point he had wanted to make was that we should get our architecture from within, and not apply it from without. We did not want an imported style. The Gothic Revival, of course, was not a revival of spirit, but a revival of form. He agreed that things changed, but the moral sentiments never changed. It was out of those moral sentiments—love and truth—that the finest things had come or would come. He had introduced Shakespeare because he wrote of the salient points in our national character.

IN PARLIAMENT.

(By our Press Gallery Representative.)

The University of London.

In the House of Commons, Sir Philip Magnus, the member for London University, asked whether the Government had appointed a trustee or trustees in connection with the proposal for providing a site in Bloomsbury for the headquarters of the University of London, and whether the Senate of the University had been informed of the proposal and had expressed any opinion thereon.

Mr. Asquith, in reply, said: The Government have not appointed a trustee or trustees for the purposes described. A body of trustees is, however, being constituted, one of whom is a member of the Government, to receive gifts offered in connection with the recommendations of the fourth report of the Royal Commission on University Education in London. A generous gift has been made on condition that a particular site is acquired. The question of its suitability is one affecting the future organisation of the University, a matter on which the Senate has found itself unable to offer any evidence to the Royal Commission.

Sir Philip Magnus asked if he might take it that the Senate had not been consulted.

Mr. Asquith replied that the hon. gentleman must draw his own conclusions.

Sub-letting of Government Contracts.

Mr. Tyson Wilson asked Mr. Benn, as representing the First Commissioner of Works, whether the present policy of the Office of Works was not to permit any sub-letting of contracts or parts of contracts, unless good and sufficient reason

was shown; whether when tenders were being considered it was considered to be a point in favour of a firm if it was in a position to execute the whole of the work itself, or whether the question of sub-letting was not raised at the time; and whether the department would in the future restrict sub-letting as much as possible.

Mr. W. Benn, in reply, said: No sub-letting is allowed without the consent in writing of the Department, and that consent is only given when the Department is satisfied that the sub-letting is in accordance with the custom of the trade. In inviting tenders for building work, the Department informs tenderers that sub-letting is only allowed where unavoidable, and asks them to state on their tender which trades, if any, they would find it necessary to seek permission to sub-let. The Department will, as heretofore, restrict sub-letting as far as possible.

School of Architecture.

In the report of the Board of Education for the year 1910-11 it is stated that in the School of Architecture connected with the Royal College of Art there were during the first term twelve students in the Upper Division and fifty-eight in the Lower Division. The Lower Division students followed the introductory course of measured studies of historic examples from the Museum and other sources, followed by a series of subjects in design. The advanced students afforded assistance in superintending the work of the several groups into which the large class of 58 was subdivided, thus gaining experience in tuition work. The Upper Division students during the first term dealt with subjects in groups and individually. Five advanced students prepared designs for the façade of a royal palace in the modern Renaissance manner. During the second term all the students undertook the same subject. Preparatory studies were made in the Department of Drawings, and of examples of Italian colour decoration in the Museum, followed by a fully worked out design for a small domed church decorated in colour. Eighteen students of the Lower Division continued their studies for a second term.

School of Decorative Painting.

In the School of Decorative Painting there were during the first term 22 students in the Upper Division and 17 in the Lower Division. In the second term there were 24 in the Upper Division and 26 in the Lower Division. The great interest of the year has been the opportunity of actually working *in situ*. The Upper Division has been principally engaged in designing, preparing, and carrying out wall and ceiling panels in the lower corridor. The impetus and interest afforded to the students by actually working for a definite site has materially benefited and improved the work. The subjects for the monthly competitions in connection with Mr. B. A. Spencer's lectures have been incidents in the history of London.

The King Edward Memorial.

In the House of Commons, on March 27th, during the debate on the second reading of the Consolidated Fund Bill, Captain Murray introduced the subject of the proposed King Edward Memorial in Green Park. He defended the right of the House of Commons to discuss the question of placing statues in royal parks. He held that in a large city like

London every tree, every leaf, and every blade of grass was worth untold gold. People did not sit in the parks to feast their eyes on statues and memorials. While admitting that the Green Park site was better than the one originally selected by the Memorial Committee, he thought there were few who would say that it was a good site. He hesitated to express an opinion about the memorial itself. He did not think it was artistic, and he did not think it was sufficiently well chosen for the particular site. He had hoped that there would have been a simple equestrian statue. If Mr. Wedgwood Benn, representing the First Commissioner of Works, could assure him that the Shadwell Park scheme could not be proceeded with unless the Green Park site was finally selected, and if, further, he would take into account the considerable feeling that existed against placing memorials and statues in the parks, and if he would be further prepared to give an undertaking to the effect that in future no more statues or memorials should be placed in the royal parks, then he (Captain Murray) would use any little influence he had to restrain any further opposition to the Green Park site, and would do everything to ensure the two schemes going through as soon as possible.

Mr. Whitehouse thought it would be unfortunate if they indefinitely extended this principle of putting large memorials involving a great amount of building in the public parks. He maintained that the Office of Works must not be free from the restraints imposed upon it by the canons of art. He had carefully studied the miniature model of the proposed King Edward Memorial with profound disappointment. He had nothing to say regarding the eminent sculptor and the eminent architect who had been associated in this matter, but he thought it would have been of very great advantage to the artistic merits of the memorial if the Office of Works had thrown open the design for competition. He thought it would have been desirable to have exhibited the alternative design of the sculptor who was responsible for the accepted design, a design which showed an open colonnade which would give from Piccadilly a long view of the grass and trees behind. He suggested that the height of the memorial was a very serious drawback to its merits. It was fair to state that the height could only be justified on the assumption that the memorial was to be studied from a great distance, but people who desired to see the statue were likely to be near it. He pleaded for the most careful guardianship not only of open spaces as open spaces but of their artistic amenities. He hoped for an undertaking that the public parks would not be regarded as the dumping ground for memorials.

Mr. Noel Buxton also spoke against the encroachment upon public parks. He hoped it was not too late to withdraw the proposal for the Green Park Memorial, and bring forward another for a much greater memorial at Hyde Park Corner.

Mr. Ormsby-Gore, though agreeing with the view that the Green Park was a most undesirable place for a large architectural and sculptured monument, said that when a committee had chosen an architect and a sculptor, it was of no use that House crabbing the design. They might quarrel about old masters as much as they liked. They did not suffer. But that was not the place for criticism of living artists, and of the work they had executed. He thought there were a great many merits in the design. The

chief fault was the place in which it was to be put. The setting would not give it a fair chance, but the actual model seemed to him to have some very striking merits. At any rate it was simple. It was not overburdened with sculpture, and the main lines of the architecture were not weak. It was a good strong architectural elevation, with columns. The criticism that the St. George and the Dragon emblem would not be seen was an absolutely unfounded criticism, and he thought that that small group was by far the best sculpture in the whole design. It followed one of the finest designs that had ever been made, and that was the design we had on our coin. One suggestion he had to offer was that the architectural part of the design should not be executed in white marble. Anything more unsatisfactory than the appearance of the Marble Arch it would be difficult to find. White marble was effective, but in process of years it was affected by the atmosphere and the acids of London, and they might scrub it with spirits of salt and other things, but they seemed to drive a sort of smokiness into the surface of the stone. He suggested Portland stone. To put white marble in the Green Park, against the background of the Naval and Military Club, would cause considerable ugliness, and would not add to the merits of the project. They did not want an imitation of the Thiergarten at Berlin.

Mr. Wm. Pearce thought that if there was further delay it might interfere with the success of the other part of the King Edward Memorial scheme—namely, the provision of Shadwell Park for the residents of the East End.

Mr. Wedgwood Benn, replying on behalf of the First Commissioner of Works, said he was not called upon to defend the artistic merits of the memorial, although, were it necessary, he was thankful to think he had such an ally as Mr. Ormsby-Gore. The House had to consider whether they would permit the First Commissioner of Works to grant permission for the memorial to be placed in Green Park. He did not think the plan would bear out the contention that there was any real encroachment on the rural amenities of the Green Park. As to the Shadwell Park scheme, he would say that the two parts of the memorial scheme were independent. With regard to the material for the architectural part of the memorial he stated that it was not intended to use marble, but Portland stone. The memorial would be 43 ft. high, 21 ft. broad, and 16 ft. deep. The statue of the late King would be 8 ft. 10 in. in height. By putting in the masonry they got over the very great difficulty of having the statue facing the Queen Victoria Memorial, and turning its back to Piccadilly, or *vice versa*. The site for the memorial would be given by the First Commissioner of Works, and consequently would cost the Memorial Committee nothing at all. At present £112,000 was available for the Committee, and Sir Vezey Strong and the other members hoped to raise that to £130,000. It was proposed to spend on the memorial in the West End £20,000, and £110,000 on the Shadwell Park scheme. The Committee proposed to buy the Shadwell Fish Market and convert it into a park. The area was about eight acres, and the cost was estimated at £110,000. They proposed to reclaim three-quarters of an acre of the foreshore for the park. It was to save money for this purpose that it had been necessary to reject the other schemes which had been submitted before the Green Park scheme was adopted. He thought the Committee had succeeded in

putting forward a plan for erecting a worthy memorial in a suitable place near the Victoria Memorial, but not in competition with it, and they had attained another object with which the late King would have warmly sympathised. They had secured a park which would be for ever a source of well-being and delight to thousands of his poorest subjects.

Lord Balcarras said it was obvious from the plan in the Tea Room that the design finally accepted was a compromise brought about either by pressure of public opinion or the criticism of the Committee. He afterwards deplored the encroachments made upon public parks for the purpose of erecting statues.

The subject then dropped.

CASEMENTS.

An excellent catalogue dealing with casements and steel sashes has recently been issued by Messrs. George Wragge, Ltd., Wardry Metal Works, Salford, Manchester (London office: 209, Shaftesbury Avenue, W.C.). Like other catalogues now issued by leading firms for the building trade, this is admirably produced, being illustrated by sections of the numerous varieties of casements and sashes obtainable, and by photographic views of buildings in which these have been fitted. The sections are specially useful, for they show exactly, and to a large scale, how the parts come together. Sections through the head and sill are given, as well as plans of the jambs, and in this way all the essential particulars are presented, so that there is complete material for making a choice. Messrs. Wragge have had many years of experience in the making of casements and steel

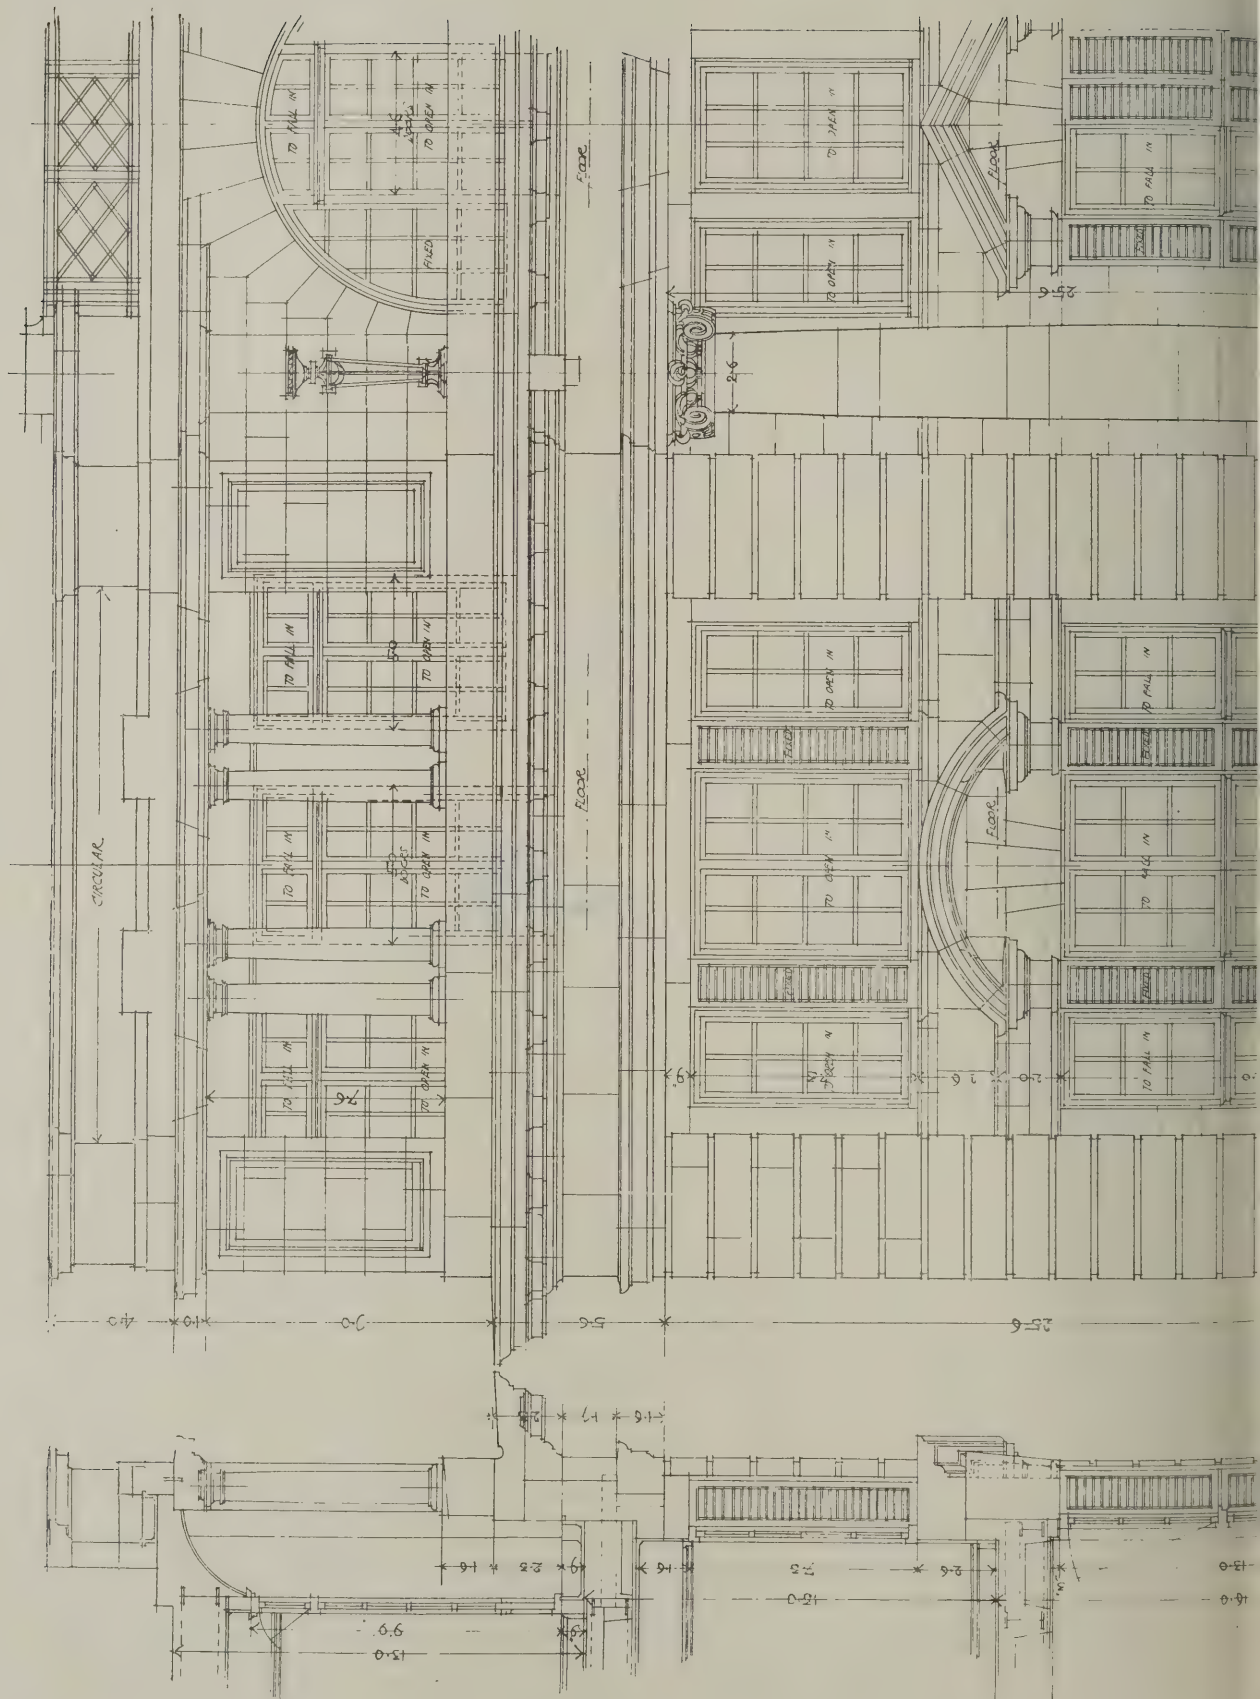

sashes, and, as a result, they have determined certain sections which, after test in the firm's workshops and in actual use, are proved to be thoroughly efficient and satisfactory. With a casement, of course, efficiency means weather-tightness, but there are also the additional requirements of ease of opening and fixing, as well as means for holding the casement at any point. Suitable fasteners and stays have been devised for this purpose, and in the catalogue before us we see a large number of good patterns. The modern casement is free from the defects which were formerly too noticeable, and its use is to be recommended both for private and public buildings, where abundance of light and neatness of effect are desired.

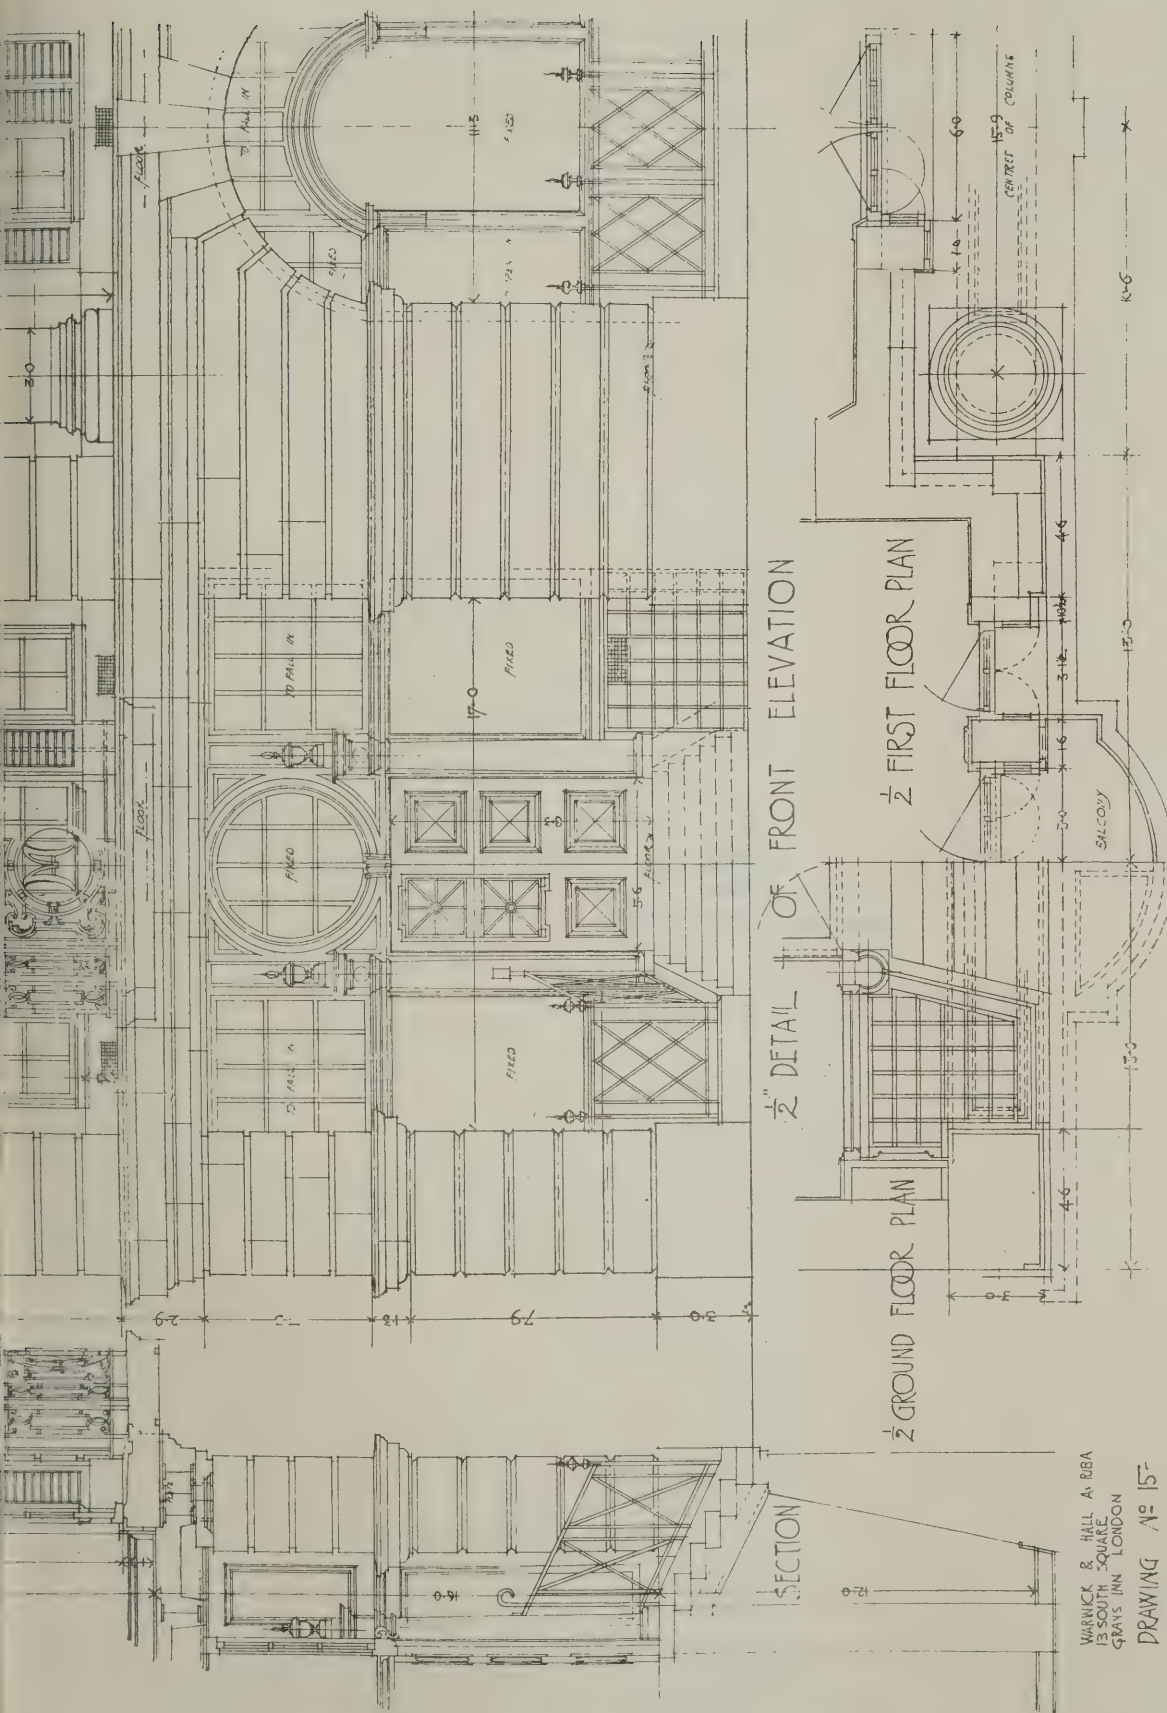

Houses by Mr. Edgar Wood and Mr. Walter Cave, among others illustrated in Messrs. Wragge's catalogue, serve as good examples of the employment of modern casements, while buildings like the Mersey Docks and Harbour Board Offices at Liverpool; the new G.P.O., London; the Royal Infirmary, Manchester; and the Glasgow Parcel Post Office are among some in which Messrs. Wragge's sashes have been employed; these, and others, are ample evidence that the modern steel sash window is excellently adapted to modern needs, while at the same time affording considerable scope for architectural treatment.

Messrs. Wragge guarantee weather-tightness, provided that the rebates are approved by taem, and that the fixing and glazing have been satisfactorily carried out. An example of a window fitted with their casements is shown on this page. Its merits are self-declared.

WARWICK AND HALL, ARCHT.

NOTES ON THE L.C.C. DRAFT REGULATIONS FOR REIN- FORCED CONCRETE,

BY PERCY J. WALDRAM, F.S.I., LIC.R.I.B.A.

The following notes are those to which attention is drawn in an editorial note on an earlier page :

Compulsory Calculation by the Straight-line Theory.

Instead of stating that the permissible stresses are calculated by the straight-line theory, it is stipulated in Clause A that reinforced concrete *shall* be calculated on that theory—namely, on the assumption that cross-sections of a member which are plane when that member is straight remain plane after it deflects under load. In other words, that the stress-strain curve of reinforced concrete is a straight line. Although this assumption is a very convenient one, and although it is probably very nearly true of concrete reinforced with efficient shear members, it is *not* true of plain concrete in compression. It would appear to account for a marked difference between theoretical and actual deflections, and it may possibly serve to modify theoretical assumptions in the near future.

Any such modification may or may not have material results upon practical construction, but the fact of its being even remotely possible is a most cogent reason why the Local Government Board should insist upon the regulations being subject to automatic periodical revision by the Council and the four Institutions concerned, say, every two or three years. Such revision could do no harm, and, what is more important, it would secure to the public the results of further research. There is little inducement for any busy practical man to endeavour to evolve new and better theory or practice when he knows that if his results do not exactly square with the regulations they will stand very small chance of being even listened to.

Scope of the Regulations.

According to Clause 23 of the 1909 Act, the regulations were intended to refer to buildings "wholly or partly of reinforced concrete." It is by no means clear which, *if any*, of the clauses refer to reinforced concrete used in any position in a building, and whether all must be complied with in order to justify the relaxations of the Building Act in favour of thinner walls scheduled in Part V. No hardship would be involved by making at least the majority of the clauses applicable to all reinforced work, and authority to do so appears to exist in the wording of the parent Act. If they are necessary for special buildings they are desirable for all.

Wind-Pressures.

It is noticeable that Clauses 18a and 18b specify wind-pressures which are more in accordance with known facts than those specified in the parent Act. This has been objected to on the ground of want of uniformity; but it shows a healthy desire to conform with the advance of knowledge even at the expense of consistency, and should be retained. At the same time it affords a striking example of the difficulties likely to be involved by attempting to give theory a legal status without providing automatic machinery for its revision. We have been studying wind-pressure for 100 years. For some fifty years past we

have accepted the view that a pressure of 56 lb. per foot super. was a proper and reasonable measure of its effect. Only three years ago an Act was passed recognising that 30 lb. over large surfaces was all that could be insisted upon, but already this has had to be reduced *under the same Act* to 20 lb. Is our present theory of an almost new subject likely to be any more infallible?

It is obviously impossible to attempt to review the whole of the 160 clauses in detail; but a few brief examples may be given of points which would certainly appear to need further consideration.

Depth of Beams.

Clause 23 limits the depth of beams to $\frac{1}{24}$ of the span, but removes that restriction on beams whose *calculated* deflection is less than $\frac{1}{800}$ of the span. It does not state what load this deflection is to be calculated for, neither does it state the method of calculation nor whether allowance is to be made for the concrete in tension, which seriously affects the actual deflection. It further ignores the fact that a deflection of $\frac{1}{800}$ is a most serious deformation, indicating stresses of about 700 to 900 lb. on the concrete even on beams $\frac{1}{24}$ of the span in depth, and, of course, more on beams of greater relative depth. Later on, in Part IX. (Testing), the same deflection is made the criterion of strength. If ever it becomes customary to test beams as at present constructed until deflections of much more than $\frac{1}{800}$ are registered, it is to be hoped that district surveyors will be content to view such tests at a safe distance.

The restriction of depth by means of a calculated deflection of $\frac{1}{800}$ will not even effect its object, because the calculated deflection on *all* beams over $\frac{1}{24}$ of the span in depth and stressed up to 600 lb. on the concrete would necessarily be less than $\frac{1}{800}$ even if the effect of concrete in tension be neglected.

Bending Moments.

The stipulated bending moments on supported slabs (Clauses 28 to 29a) are apparently those derived from the theoretical deductions of Rankine and Grashof, who can hardly be considered as authorities on reinforced concrete. The latest American code of regulations (see "Architects' and Builders' Journal," February 28th, page 234) require such slabs to be calculated for bending moments 300 per cent. to 400 per cent. greater.

Working Load.

The use of steel stressed up to 20,000 lb. per square inch working load (namely, nearly 30,000 lb. test load), Clauses 135 and 136, for slabs without compulsory shear members, is certainly open to question. Under such stresses the concrete in tension is certain to crack, and thus offer a direct invitation to failure by the most common cause of all—namely, diagonal shear tension.

This is all the more important in that the latter is not recognised at all, and the limit of stress in concrete in pure shear (60 lb. per square inch) would be accompanied by diagonal tensions which could hardly have a factor of safety of A. The New York Regulations limit the permissible stress to 16,000.

Wanted—A Few Definitions.

The Regulations would be decidedly improved by a few definitions, especially as in many instances one finds what is apparently the same thing referred to in different ways.

Thus, in Clauses 42 and 50 the terms "ends bent into the form of a hook," and "ends bent to a J form," may or may

not mean the same thing. But neither is defined, although the minimum inner diameter of hooked ends is by no means an unimportant matter. The same clause leaves the reader in complete doubt as to whether the length of bar necessary to form the hook is part of the stipulated grip length or not.

Again, in the space of only 5 clauses (Nos. 86, 87, 99, 101, and 102), determining the permissible load on columns, we find no fewer than ten expressions—stress, full stress, working stress, stress on the concrete in the area bounded by lateral reinforcement, working compression stress on the concrete of the hooped core; load, safe load, and working load, maximum permissible pressure, and total permissible pressure. The ordinary designer would prefer a little frank tautology.

Strengths of Columns.

Clause 87 states the relative strengths of various columns as follows:—

Both ends fixed	1
One end fixed and one end hinged	$\frac{1}{2}$
Both ends hinged	$\frac{1}{4}$
One end fixed and one free end	$\frac{1}{8}$

These are the crippling factors in Euler's formula, which is true only for columns so slender that their strength varies inversely as the *square* of their length. For all ordinary columns the respective ratios of strength would be approximately 1, $\frac{3}{4}$, $\frac{1}{2}$, and $\frac{1}{4}$; and in all columns the relative strengths would be those of columns whose relative lengths were approximately as 1, $1\frac{1}{2}$, 2, and 4. It would appear that this clause might be re-drafted with advantage.

It is, of course, quite possible that these points may have been already raised by the four Institutes, who, under the 1909 Act, have to be notified of the Council's intention to apply for the L.C.B. sanction. If so, it would be very desirable for the final draft to be published before it is formally sanctioned, in order to allow the professional public and the technical press an opportunity of offering suggestions.

THE BUILDING TRADE IN NEW SOUTH WALES.

We are in receipt of copies of the annual report of the Master Builders' Association of New South Wales for the year ending January 23rd, 1912, from which it should be possible to glean facts and inferences that may afford a means of useful comparison with present conditions in our own country.

The opening sentence is jubilant: "The year now closing has been one of record progress in the building trade of the State of New South Wales." It is further recorded that, as far as the City of Sydney is concerned, the process of adding further storeys to existing buildings has almost entirely ceased, the work carried out having mainly consisted of filling up the few vacant spaces and pulling down and entirely rebuilding on modern up-to-date lines. The increasing value of land has caused owners to erect much higher buildings than were customary a few years ago. One building, the contract for which has been let during the latter part of this year, will reach when completed a height of 165 ft. above the footpath, or 192 ft. from basement floor to roof, and will contain fourteen storeys, constituting a record for high buildings in Sydney. The City Council has continued its policy of erecting new markets and demolishing some of the

old slum areas for the purpose of widening existing streets or forming new ones. This policy has no doubt been an important factor in the increased demand for buildings of a small residential character which have been erected by speculators, thus assisting to accentuate the shortage of labour. The general prosperity of the country shows no sign of declining, and its effect is of course felt by the building trades; and there seems to be no diminution—in fact, there has been apparently an increase—in the number of buildings erected for the purposes of amusement, such as picture shows, theatres, skating rinks, etc. The capital cost of the buildings actually completed in Sydney during 1911 is returned by the Board of Water Supply and Sewage at £3,825,182, as compared with £2,569,529 for 1910. Bricks cannot be turned out fast enough to meet the demand. All the yards are producing all the bricks they possibly can with their present plant and labour, and they are selling every brick they make. In fact, builders are compelled to wait for supplies for at least six weeks from the time of ordering.

If only there were an adequate supply of labour and materials, the prospects of the near future for the building trade would be in every respect brighter than they have ever been in the history of the State. There is a large amount of work waiting to be started, the difficulties of obtaining sufficient men and material having caused the architects in many instances to wait a little longer before building. The demand for residential houses and cottages is greater at the present moment than it has ever been before in Sydney and the suburbs.

The shortage of labour has become more marked than it was during the preceding year. Of course it was not confined to the building industry; and a Royal Commission of Enquiry was appointed; and representatives of the Association gave evidence of their actual need of 587 men of different trades. The various trade unions had contended that the "alleged" shortage was imaginary; but the stonemasons admitted a shortage, although they contended that it was only temporary; while the bricklayers' society preferred not to give evidence. In the

experience of the Association, the shortage in the early part of the year was felt most keenly in regard to masons, and during the latter part of the year there was more need of plasterers and bricklayers. The only results of the enquiry, so far as Government action is concerned, are "a few well-considered platitudes from the Premier." Immigration, assisted by the Government with reduced passages, is thought to be the only remedy.

The Labour Government has started carrying out works by the day-labour system. The present Minister of Works has gone a great deal further even than the preceding Minister, the late Mr. O'Sullivan, in this policy, and has started State brickworks, a State blue metal quarry, a State timber yard, and a State lime-kiln, and proposes also to start a State cement works. In carrying out the day-labour policy, the Government thought fit to retire Colonel W. L. Vernon, who had been Government Architect for more than twenty years, and had earned the respect and admiration of everyone who had had any business relations with him. On his retirement he received presentations from different bodies, and the Association "could not let such an event take place without showing their appreciation of his many years' services to the State, and his great ability and fair dealing."

During the year under notice, the relations between the Institute of Architects and the Association have continued upon an excellent footing. The demand for the Association's Conditions of Contract has still further increased, and no disputes between architects and members have been brought before the committee. The Institute, however, has put forward revised conditions of contract proposed in substitution for those now in use.

For some cause not exactly known, the Government appointed a Royal Commission to enquire into the practices that existed in relation to prime cost items in Government contracts, and in spite of the strongest evidence that the practice of builders receiving trade discounts from merchants in connection with these items was universal and world-wide, and should be openly recognised, the Commission stigmatised these discounts as "illegal commissions." The Association has taken the matter into consideration, and has decided that the new Committee shall take early steps to confer with the Institute of Architects with a view to obtaining an amendment of the P. C. Sums Agreement, if possible on similar lines to that arrived at recently by the Melbourne Association with the Victorian Institute of Architects. This agreement, arrived at after some years of very serious trouble, appears to be a very satisfactory one, and an improvement on the agreement entered into some years ago in this State.

Industrial disputes during the year included a demand by the slaters for an increase of 1s. per day, which they got after a strike, the master slaters weakening owing to a lack of unanimity among themselves; a settlement with the carpenters, whose demand was for an increase of wages to 1s. 9d. per hour; an award to the quarrymen of an increase of wages and a reduction of hours to forty-four per week on the ground of the unhealthy character of the occupation; a slight increase of wages to the painters and decorators; and a variation of the award to sawmill and timber-yard employees. The continual variation of awards, and the frequent alteration of the laws regulating labour, cause considerable vexa-

LEAD-COVERED BAY TO BUSINESS PREMISES IN LEICESTER. EVERARD, SON & PICK, ARCHITECTS.

tion and harassment to employers, and constant ferment among employees.

The Workmen's Compensation Act, which came into operation on January 1st, 1911, while it has imposed on the employers a considerable increase in the cost of insurance, does not appear to be at all satisfactory to the employees; and already an amendment of the Act has been brought forward, but, owing to Cabinet changes, has been shelved.

The apprenticeship question is being dealt with by the Royal Commission on the shortage of labour, and its report is awaited with interest.

The report is signed by Mr. A. E. Boroughs, president, and Mr. N. Phelps-Richards, secretary.

INSTITUTE OF BUILDERS.

The twenty-eighth annual general meeting of the Institute of Builders was held at the offices, Koh-i-Noor House, Kingsway, W.C., on March 20th.

The minutes of the last annual general meeting were read and confirmed, and the audited accounts of the Institute and of the Institute Benevolent Fund were submitted by the treasurer (Mr. J. Carmichael, J.P.), and were adopted.

The following officers were elected for the ensuing year: 1. President, Mr. H. Arthur Bartlett (Messrs. Perry and Co. (Bow), Ltd.); 2. Vice-presidents (1) Mr. Ernest J. Brown; (2) Mr. F. G. Rice (Messrs. Rice and Son); (3) Mr. E. J. Strange (Tunbridge Wells); (4) Mr. Leonard Horner (Messrs. Ashby and Horner). 3. Treasurer, Mr. F. L. Dove L.C.C. 4. To fill vacancies on the Executive Council: (1) Mr. A. B. H. Colls (Messrs. Trollope and Colls, Ltd.); (2) Mr. Walter Lawrence, jun. (Messrs. Walter Lawrence and Son); (3) Mr. F. M. May (Messrs. Holland and Hannen and Cubitts, Ltd.); (4) Mr. James F. Parker (Messrs. Patman and Fotheringham, Ltd.); (5) Mr. E. S. Rider (Messrs. T. Rider and Son); (6) Mr. William Willett. 5. hon. auditors: (1) Mr. Eric M. May (Messrs. Holland and Hannen and Cubitts, Ltd.) (2) Mr. G. C. Hudson (Messrs. Hudson Bros.).

A hearty vote of thanks was given to Mr. James S. Holliday (Messrs. Holliday and Greenwood, Ltd.) for his services during the past year.

The annual report from the Council (from which extracts are given below) was approved.

Twenty-eighth Annual Report.

"The Council, in presenting the annual report, regrets that although the building trade has to a certain extent improved, it still continues to be in a very unsatisfactory condition. For some years past the competition has been particularly acute, and this, coupled with the general unrest in the country and the prospective heavy burdens about to be imposed on employers by the Legislature, render the prospects of a desirable change anything but promising.

"Attention has been given to Parliamentary matters affecting the building trade: steps have been taken to try to effect such changes as are desirable in existing Acts, and to judiciously modify Bills of importance before the House of Commons. In these matters the Council has been glad to co-operate with other bodies.

"The Council has given much time and care to the formulation of an Agreement for Sub-Contractors who are specified by architects, and to the alterations

which this document entails in the Agreed Form of Contract. The proposed Form of Sub-Contractor's Agreement was submitted to the National Federation, being one of the signatories of the Agreed Form, and was practically approved. It was then brought informally before the R.I.B.A. at a Conference on the subject, and it is now under the consideration of that body.

"The President, Colonel Geo. Haward Trollope, and Mr. J. Styles kindly gave evidence before the Home Office Departmental Committee, which Committee was appointed to investigate the dangers attending the use of white lead in the preparation of paints. Having considered the matter most closely, the Council came to the conclusion that, in the interests of the trade, it would be preferable to endeavour to exclude altogether the use of white lead than to have exacting regulations introduced by the legislature which would be very irksome to employers.

"Mr. F. G. Rice is the representative of this Institute on the Home Office Committee, and the Building Trade is under great obligations to him for his close and valuable assistance in the matter.

"The movement to re-establish a system of apprenticeship has occupied the attention of the Council, and suggestions have been submitted to the London County Council which are now under consideration.

"The existence and utility of technical schools, proper discipline, payment of premiums, etc., are matters which affect this question and need careful consideration.

"Your Council and the Council of the London Master Builders' Association jointly took part in the consideration of Suggestions made by the Quantity Surveyors' Association on the question of Items to be Embodied in all Preliminary Bills. The results of the Councils' comments on the suggestions were forwarded to the Q.S.A. in due course, and it is to be hoped that good will be derived in consequence.

"The Council awarded the following prizes and rewards to successful students at the recent theoretical and practical examinations held by the City and Guilds of London Institute:—

1st Prize for Carpentry & Joinery, Silver Medal & 30s.	
2nd " " " " " " " " " " " " " " " "	Bronze " " 20s.
1st " " " " " " " " " " " " " " " "	Silver " " 30s.
2nd " " " " " " " " " " " " " " " "	Bronze " " 20s.

"The following grants were made from the Institute Benevolent Fund: Builders' Benevolent Fund, £100; Builders' Clerks' Benevolent Institution, £10 10s.; Provident Institution of Builders' Foremen and Clerks of Works, £10 10s."

LONDON MASTER BUILDERS' ASSOCIATION.

The Council of the London Master Builders' Association met on March 21st, when Mr. James S. Holliday (president) was in the chair.

The report of the Bricklayers' Conciliation Board meeting held on March 14th was read, and the Finance Committee's report was read and approved.

The rate of subscription to the Association for the year 1912 was determined upon.

Certain legal cases were reported, and were referred to a special committee for consideration and report.

The various committees and representatives in other bodies were chosen.

Matters were considered connected with a petition to the Prime Minister against the Trade Disputes Act (1906). The petition was presented by Mr. Basil Peto, M.P.

Applications for proposed alterations in working rule agreements with the Amalgamated Society of Carpenters and Joiners and Stonemasons were received together with an application for the formulation of a working rule agreement with the labourers. They were referred to a Special Committee for consideration and report.

Various other trade matters of interest and importance were discussed.

New members of the Association were elected: (1) Ordinary Member, Messrs. Allen Fairhead and Son, Enfield; (2) Associate Member, Messrs. John Daymond and Son, Westminster. New member nominated: (1) Associate Member Messrs. Messers, Ltd.

BUILDERS' CLERKS' BENEVOLENT INSTITUTION DINNER.

The thirty-fourth annual dinner of the above Institution was held on Tuesday March 26th, at the Holborn Restaurant.

Mr. R. Dudley Bartlett, the president proposing the toast of "The Builders Clerks' Benevolent Institution," said that when he looked down the long list of past-presidents and saw the names of practically all the great men of the building trade, he felt very much like a Skipper sardine in a school of whales. The list included the names of Mr. Rider, and, no less important to him, that of H. H. Bartlett, his father, who occupied the chair twenty-one years ago. Last year he continued, the Institution had paid £760 to thirty-one pensioners, out of an income of £790 all told. Their total expenditure amounted to £870. The ordinary income, together with dividends fell short of this amount, which had to be collected. The Institution had paid altogether £15,000 in pensions and nearly £1,000 in presentations to orphan working schools.

Mr. H. A. Bartlett, president of the Institute of Builders, proposing the toast of "The Architects and Surveyors," said that the modern architect was a compendium of useful knowledge. He had to be artist, lawyer, engineer, sanitarian, expert, financier, and diplomatist; but he (the speaker) objected to the architect taking on the business of building. At the present rate, the builder would soon cease to exist, becoming merely the agent for sub-contractors. He hoped it would some day be realised that a builder could do a bit of joinery and dig a hole without the intervention of an expert. With respect to the surveyors, it was really extraordinary how those gentlemen managed to satisfy all parties.

Mr. Chas. Frankiss having replied for the architects,

Mr. Walter Lawrence, responding for the surveyors, said, with reference to industrial unrest, that if there were no piecework there would be fewer strikes. With regard to the Institution, he believed that a more direct appeal to architects and surveyors would meet with generous response. Speaking for the surveyor, he was only too glad to testify to the fine feeling which always existed between surveyors and builders' clerks.

Mr. F. S. Oldham, proposing the toast of "The Builders and Builders' Merchants," mentioned that Mr. Rider who would reply to the toast, was President of the Institution during 1878-9.

Mr. Thomas F. Rider replied for the builders, recalling the first dinner of the Institution in the Guildhall Tavern, Cheapside.

Mr. Alexander Ritchie, responding for the builders' merchants, said that the builders' clerks were getting as bad as the architects and surveyors. He entreated them to forsake the little ro in. by 12 in. window and the notices saying that no one could be seen except by appointment.

Mr. John Austin, the secretary, then announced that, including a gift of twenty guineas from the president, the subscriptions amounted to a total of £414 2s. 6d.

Mr. Leonard Horner then proposed the toast of "The President," to which Mr. Bartlett replied.

SMOKE ABATEMENT CONFERENCE.

At the conference on Smoke Abatement, held in connection with the Smoke Abatement Exhibition at the Agricultural Hall, Islington, seventy-one public authorities, including nine foreign municipalities, were represented, and the Swedish Government and the Dutch Ministry of Commerce sent delegates.

Sir Arthur Church said that, whatever the injurious effects of the carbon and mineral matters in smoke, it was not to these constituents that the damage done by coal smoke to building stones, to mural paintings, and to objects of metal could be attributed. The offending constituents of soot were those associated with, and absorbed by, the carbon which formed its basis, notably sulphur compounds. Many instances of decayed stonework in cities might be cited to prove this point. The outer face of the Sheldonian Theatre at Oxford contained 19 per cent. of gypsum, all, save the veriest trace, formed from carbonate of lime by the attack of atmospheric sulphuric acid; and Magdalen College Tower gave more than 11 per cent. The interior walling of Westminster Chapter House contained just 18 per cent. of the same product, while in St. Paul's Cathedral the black stalactitic incrustation hanging to the underside of the cornice above the colonnade and below the dome, which was some inches deep in places, contained nearly 74 per cent. of gypsum. The abatement of the smoke nuisance, or even its entire abolition, however great the advantages to health and comfort, would not get rid of the injury and pollution caused by sulphuric acid.

Mr. Noel Heaton contended that it was scarcely too much to say that the smoke nuisance had in towns rendered the execution of a satisfactory and permanent work of decorative painting one of the most difficult problems of applied chemistry.

The effect of town air on metal work was the subject of a paper by Dr. S. Rideal; and Mr. Harry Redfern, on behalf of the Society for the Protection of Ancient Buildings, dealt with the effect of smoke on buildings.

Mr. R. G. K. Lempfert, superintendent of the Forecast Division of the Meteorological Society, by a comparison of the sunshine statistics of urban and rural stations, showed that the general impression as to the diminution of fog in London during recent years was confirmed by official figures, and that the ratio of town to country sunshine had no tendency to return to the low values recorded in former years. While it was

impossible to attribute the differences in the duration of bright sunshine entirely to the effect of smoke, it was not unreasonable, he thought, to attribute regular and progressive changes in the ratio of town to country sunshine to that cause.

Smoke and fog was the subject of a paper by the Hon. Rollo Russell, who pointed out that the last ten years had been remarkably free from dense fogs, not only in London, but in the South of England generally. The worst offender was the domestic fire, as was proved by the fact that the darkest fogs had been on Sundays and Christmas Day.

At the concluding meeting of the Smoke Abatement Conference Dr. H. A. Des Vœux read a paper in which he urged that the Government should appoint a Royal Commission to inquire into the whole subject of smoke abatement. The Act passed in 1878, he said, had been a failure, and the time had come when the cause of that failure should be inquired into by an impartial tribunal. He concluded by moving a resolution recommending that the offer of Mr. Gordon Harvey, M.P., to introduce into Parliament the Smoke Abatement Bill prepared by the Smoke Abatement League, be accepted, and that, failing any prospect of the Bill being passed next year, steps should be taken to organise a deputation to the Government to urge the appointment of a Royal Commission. The resolution was carried.

Other resolutions were passed advising that steps should be taken to study the economic phases of smoke pollution, and impressing on local authorities the importance of establishing classes for the training of stokers and the granting of certificates of competency.

LEGAL.

Who Pays the Quantity Surveyor?

At Leicester County Court, R. E. Carpenter and Son, quantity surveyors, sued Edward Baxter, for £28 14s. 10d., for professional services, etc. On behalf of the plaintiffs it was stated that the defendant had contemplated erecting a house, and plaintiff claimed 2½ per cent. on the lowest tender sent in for the erection of this house, and £4 10s. in respect of payments for printing. Mr. Carpenter received his instructions from the architect for the defendant. The plan was sent to M. Carpenter, and quantities were submitted to the architect. Subsequently when the tenders were sent in the cost was far over £500 (the lowest being £880), and Mr. Baxter then decided not to build.—For the defence it was contended that there was no case against the defendant. If a debt had been incurred it should be recovered from the architect, because the architect had no authority to pledge the credit of the defendant.—His Honour said it seemed to him to be merely a question of who should pay. There was no question about the work being well done.—Defendant said he gave the architect instructions to get out plans for a house not to cost more than £550, and repeatedly told him not to go beyond that figure.—Mr. J. B. Withers, president of the Sheffield Society of Architects, said it was not the custom among Sheffield architects to employ quantity surveyors to take out quantities. He only knew two such cases, including the present.—His Honour, in giving judgment, said this was not a question whether Mr. Carpenter

had done his work; the question was who was to pay him? The plaintiff had not, in his opinion, made out that the architect in this case had the authority to pledge the credit of the building owner by employing the quantity surveyor. The architect set Mr. Carpenter to work, but had no authority to pledge the credit of his client beyond £550. He therefore found for the defendant.—A stay of execution for 21 days was granted, notice of appeal being given.

NORTHERN COUNTIES FEDERATION OF BUILDING TRADE EMPLOYERS.

A quarterly meeting of the board of representatives of this Federation was held at the Corporation Hotel, Middlesbrough, on March 14th, Mr. John Proud (West Hartlepool), president, in the chair, when 34 representatives were present.

The Executive Council had sent a resolution to the Government requesting an extension of the date at which the National Insurance Act should come into operation; but the Secretary reported that the Act would come into force on the 15th July next, an authoritative pronouncement having been given that the date would not be extended. The Insurance Commissioners had been approached with respect to their issuing explanatory instructions respecting the working of the Act, and had replied that the same had been under consideration, and would be issued shortly.

The Executive Council recommended support of the principle of the Trade Dispute Reform League's Bill to explain and amend the law relating to trade unions and trades disputes.

The secretary presented a tabulated statement of the stonemasons' working rules within the Federation area, together with the proposed alterations.

It was resolved that the Federation should invite the operative stonemasons to meet the representatives of this Federation to discuss the question of having a uniform worked stone rule for the whole of the Federation area.

The Executive Council reported that the secretary, at the request of the Darlington Association, had visited Darlington, and with a deputation of the Darlington Association had waited upon the Streets Committee and discussed with them the conditions of contract with the Darlington Corporation. The points at issue were the arbitration clause and the question of payments. The interview was considered very satisfactory, and it is believed that the Darlington Association will obtain the amendments sought. A request for the adoption of the National Form of Contract by the Streets Committee and the Corporation was preferred, and would be further considered by the Corporation. Correspondence with H.M. Office of Works upon the conditions of contract in connection with the Darlington new Post Office was read. The form used by H.M. Office was in accordance with the general requirements of the Federation.

A letter was read from the National Federation covering a letter from the Institution of Municipal and County Engineers with respect to priced schedules. The Institution's letter was to the effect that the Council of the Institution are of opinion that it is not necessary or desirable that Priced Bills of Quantities and Schedules should be sent in openly with tenders, but that it is

essential that the prices in the bills of quantities and schedule should be approved by the engineer before a tender is recommended for acceptance, and that the Council of the Institution will be prepared to recommend the members to adopt this principle in future contracts.

The letter was received with satisfaction, and it was resolved that the letter should be circulated among the members.

The Secretary reported that the Leeds Association had received notice from the joiners for an increase of wages from 9d. to 10d., and that at Bristol a strike exists, the men having refused an offer of $\frac{1}{2}$ d. advance and demanding 1d.

It was agreed to hold the next quarterly meeting at North Shields in June next.—*Condensed from Report by W. H. HOPE, Solicitor, Secretary.*

NEWS ITEMS.

Rebuilding of Chelsea Hospital for Women.

At the annual meeting of the Chelsea Hospital for Women, which was held last week, Lord Castlereagh announced that a site of an acre and a quarter had been presented by Lord Cadogan for the purpose of rebuilding the hospital.

Institute of Sanitary Engineers.

The examination board of this Institute recently submitted to the Council of the Institute a report recommending the reorganisation of their examinations upon a broader basis. The Council has now adopted the report, a new syllabus has been drawn up, and the Board of examiners has been augmented. The new scheme will be in working order for the next examinations to be held in May.

London Master Builders and "Peaceful Picketing."

In the House of Commons, on March 25th, Mr. Peto presented a petition from members of the London Master Builders' Association praying the House to pass legislation without delay providing that the number of men constituting a picket during trade disputes should be limited to two—(derisive Labour cheers)—and should be permitted only to attend a place where a person works and carries on business, and making all unions, whether of masters or of men, responsible for their acts the same as ordinary citizens.

Business Development.

Messrs. William Firth, Ltd., iron and steel merchants, Water Lane and Wilson Street, Leeds, announce that they are opening a branch office at Corn Exchange Chambers, Sheffield, under the management of Mr. G. Clifford Whitaker, who was formerly associated with Messrs. Whitaker Brothers, railway contractors, Horsforth. Mr. Whitaker will principally devote his attention to dealing in new and second-hand contractors' plant, etc., whilst the firm's old-established business in rails, girders, iron and steel bars, plates, etc., will be continued as before at the head office, Water Lane, Leeds.

The Iron and Steel Institute: Carnegie Gold Medal.

The Council of the Iron and Steel Institute have this year decided to award the Andrew Carnegie Gold Medal of the Institute to Dr. Paul Goerens, of Aachen. Dr. Goerens is a distinguished metallurgist, and is a member of the staff of the

Royal Technical College of that city. He has made many contributions to scientific metallurgy, and in 1910 he was awarded one of the Carnegie Scholarships of the Iron and Steel Institute, to enable him to pursue his investigations on the influence of cold-working on the properties of iron and steel. The Gold Medal is now awarded to him in recognition of the highly meritorious character of his research work on this subject, which was published last year in Vol. III. of the Carnegie Scholarship Memoirs of the Iron and Steel Institute.

Changes of Address.

Mr. Alfred Saxon Snell, F.R.I.B.A., announces that his address is now 9, Bentinck Street, Manchester Square, W.

Messrs. Gale, Durlacher and Emmett, architects and surveyors, have removed their offices from No. 33, New Bridge Street, Ludgate Circus, to No. 15, New Bridge Street (opposite). Their telephone number will in future be—City 6888, and their telegraphic address—"Galdono, London," as hitherto.

Mr. Alfred Cox, F.R.I.B.A., has moved his offices from 4, Adam Street, Adelphi, to 34, Henrietta Street, Covent Garden, W.C.

Mr. R. W. Collier, F.R.I.B.A., has removed to 5, Lancaster Place, Strand, London, W.C. (Telephone, 10427 Central.)

Glasgow Institute of Architects.

A meeting of the newly elected Council of the Institute was held last week, when the following office-bearers were elected:—President, Mr. Alexander N. Paterson, M.A., A.R.S.A., F.R.I.B.A.; vice-presidents—Messrs. J. K. Hunter, F.R.I.B.A., Charles R. Mackintosh, F.R.I.B.A., and John Watson; auditor of professional accounts, Mr. John B. Wilson, F.R.I.B.A.; secretary and treasurer, Mr. C. J. MacLean, writer, 115, St. Vincent Street. The committees for the ensuing year were also appointed. A communication received from the R.I.B.A. as to "Professional Practice and Schedule of Charges of Architects" was remitted to the Practice Committee for consideration. A letter was read from the secretary of the National Housing and Town Planning Council stating that in view of the dispute in the coal-mining industry it had been decided to postpone the conference to be held in Glasgow until April 29th and 30th next.

CORRESPONDENCE.

Street Name-plates.

To the Editor of THE ARCHITECTS' AND BUILDERS' JOURNAL.

SIR,—I have read with interest your editorial note on "Street Name-plates" in your issue of March 20th. It is certainly a matter that demands serious attention, as regards legibility, design, uniformity, and the proper place and height at the corner of a street or thoroughfare.

One point I have not seen mentioned, but which I think is of great importance, is the inability to make out a sign in the dark. If some kind of luminous name-plate or paint could be provided it would prove a boon to the public. The best name-plate I have noticed is in the form of a white tile with the name in bold black letters, burnt in. They are distinct, clean, and require no attention.

JNO. A. BARRETT.

COMPETITIONS.

LIST OF COMPETITIONS OPEN

APRIL 20TH. ADDITIONS TO SCHOOL DALBEATTIE.—The School Board of the Parish of Urr invite competitive plans of a proposed addition to Dalbeattie Higher Grade School of 3 class-rooms to accommodate 50 pupils each, and technical rooms for wood work, cooking and laboratory. Plans, with estimates of each of the works, to be lodged with James Little, solicitor, Dalbeattie, Clevenston, to the Board, not later than April 20th.

APRIL 20TH. BIRMINGHAM BLUE COAT SCHOOL.—Competition strictly limited to Birmingham architects. In a preliminary competition, three designs will be selected, and the authors will be paid £50 each to develop and redraw their plans to a larger scale, showing further details. In the event of the Government failing to proceed with the second competition, the authors of the three designs will be paid £25 each. Assessors, Mr. G. H. Hunt, F.R.I.B.A., of London, and Mr. Charles E. Bateman, F.R.I.B.A., hon. consulting architect to the Government. Drawings to be delivered by midnight of April 20th to Mr. William Bolton, Secretary, The Blue Coat School, Birmingham.

MAY 1ST. PUBLIC BATHS, WOMBWELL, YORKS.—Wombwell U.D.C. invite designs for swimming-baths to be erected on Hough Lane. Premiums, £40, £30, and £20. Stamped and addressed in a foolscap envelope to W. Quest, surveyor to the Council, Town Hall, Wombwell.

MAY 15TH. COUNCIL OFFICES, PORTLAND.—Portland U.D.C. offer premiums of £50 and £10 respectively for first and second designs. Particulars (deposit 10s. 6d., returnable) from R. A. Connatt, Clerk to the Council, Offices, New Road, Portland. [The date has been extended from that formerly announced.]

JUNE 1ST. INSTITUTE, NETHERTON, DUNFERMLINE.—Cost not to exceed £70. Premiums, £20, £15, and £10. Assessors, Mr. E. A. Jamieson. Apply, Secretary, Carnegie Trust, Abbot Street, Dunfermline.

JUNE 28TH. TOWN PLANNING, HALE.—Premiums of £50 and £25 are offered for a town-planning scheme.—Address, Council Offices, Hale, Cheshire.

JUNE 30TH. MUNICIPAL BUILDING, PADIHAM.—Designs for town hall, bath, etc., are invited. Premiums of £40 and £20 are offered. Address, J. Greggs, A.M.Inst.C.E., Surveyor's Office, Padiham.

AUGUST 30TH. THE HENRY SAXON SNELL ESSAY.—The Henry Saxon Snell prize of fifty guineas and silver medal of the Royal Sanitary Institute is offered for an essay on "Suggestions for Improvement in the Ventilating, Lighting, Heating, and Water Supply Appliances and Fittings for an Operating Room and its accessory rooms for a General Hospital of 20 Beds (no Students)." Essays (in which two competitors of different professions or crafts may join) to be delivered before 4 p.m., August 30th, to the Secretary, Royal Sanitary Institute, 90, Buckingham Palace Road, London, S.W., from whom full particulars may be obtained.

THE ARCHITECTS' & BUILDERS' JOURNAL.

WEDNESDAY
APRIL 10th, 1912.

Volume XXXV.

No. 899.

ENTRANCE LODGE TO "DERRY'S WOOD," WONERSH, SURREY
GEORGE ALEXANDER, ARCHITECT.

BANK PREMISES, NUNEATON. BATEMAN AND BATEMAN, ARCHITECTS.

These premises were erected for the Union of London and Smith's Bank and for Wm. Cawthorne and Sons, printers and stationers, in the Market Square, Nuneaton. The ground floor is occupied by the banking room, manager's room, and staircase to offices over; at the rear is the retail shop, with stores above it. The bank strong-room is in the basement, which required very careful treatment owing to flood water rising from the river a short distance away. Clipsham is the stone used for the elevations.

THE ARCHITECTS' & BUILDERS' JOURNAL.

CAXTON HOUSE, WESTMINSTER.

VOLUME 35. No. 899.

NOTE : The List of Contents will be found on page IV. of the front advertisements.

A Book on French Romanesque Architecture.

It is remarkable how much attention has been given of late years, in various important works, to the history and development of architecture during the Romanesque period. The great interest of this period of architectural history lies in the fact that in it we trace the influences which led up to the development of the

great mediæval style of architecture. Throughout the whole of this phase of architectural history we see the principles which were to govern mediæval architecture gradually struggling into existence, mainly under the influence of the experiments in roofing-in a great church in an effective and monumental manner; as Mr. Prior put it in a remarkable lecture delivered last year at University College, the business of the early mediæval architects was mainly to cover in a church in the best manner; that problem achieved, all the rest followed. A further interest in connection with the Romanesque period is that, if we trace it to its commencement, it takes us back to the first development of the plan of the Christian Church, which, as a plan, was settled in its main features before the question of its architectural treatment assumed so much importance. The early Christian churches were covered with timber roofs, which were liable to destruction, by fire. The general form of three-aisled plan being accepted, how could this be roofed-in so as to be permanent and monumental, to preserve the section with the high centre and lower side-aisles, and at the same time provide for efficient lighting of the interior? The struggle to solve this problem was what made Gothic architecture.

The latest book on this subject, by M. de Lasteyrie*, is one of the finest books on a chapter in architectural history which have been produced. It deals only, it is true, with the development of Romanesque architecture in France, which however is by far the most important, since it is out of French Romanesque that Gothic architecture arose. But the author treats his subject from the commencement, starting from the Latin basilica, out of which the mediæval cathedral arose; and on this part of the subject he has much to say that is of interest and something that is new. The book is crowded with illustrations (731 in all), and is admirably written; the author is no propounder of novel and startling theories; he treats his great subject in a thoroughly sane and logical manner, giving full reasons for all his conclusions; and has produced a work which no good architectural library can afford to be without. At present only the French edition has appeared; a translation of the book into English would be an undertaking worth considering.

In the space we can afford to it here our object will be mainly to suggest what lessons or hints for modern church architecture may be derived from the study of the subject; the interests of this journal lying more with architecture than archæology; though no architect who takes real interest in architecture as an art and not as a mere business can afford, or will be content, to overlook its past history.

But we may say a word, in the first instance, on the part of the book which deals with the evolution of the Basilica Church, a subject which M. de Lasteyrie goes into very fully. He considers that the origin of the basilica church is not so simple a question as it has sometimes been considered. The old idea that the early Christians possessed themselves of some of the Pagan basilicas and made use of them as churches has of course long ago been given up; the basilica was a business building, and was commonly open along one side, and the interior ranges of columns were returned across the ends, which would not have rendered them suitable for a church; besides which, the use of basilicas for business did not come to an end with the official adoption of Christianity; they must have been still wanted for their original purposes. The idea that the form of plan was taken from apartments in private houses, in which Christian services were first held, is opposed to the fact that such apartments can only have been found in houses on a palatial scale, and that there is no evidence of their existence except the one plan (Fig. 1) which has been, as the author says, "disengaged" from the ruins of the palace of the Cæsars on the Palatine; nor would Christians at the early period have been likely to find accommodation for their services in the houses of the wealthy. As to the apse terminating the orthodox Christian basilica church, the author points out that the apse was not so general or so necessary an adjunct to the judicial basilica as is commonly supposed; that on the other hand the apse was a very common feature in Roman buildings of various kinds; and, furthermore, that the altar, in the earliest Christian period, was commonly the tomb of a saint as well as the communion table, and the apse was a form in use already in funeral chapels. He sums up the argument thus:—

"I am convinced therefore that the origin of the Christian basilica is more complex than is usually supposed. From the basilica of the forum, the Christians took the oblong form,

FIG. 2—THE ABBEY OF RIQUIER (AFTER AN OLD MINIATURE).

the division into parallel galleries, and above all the higher elevation of the centre gallery, which allowed of the interior being lighted from above. From various public places of gathering, and also from certain funeral monuments, they took the idea of the apse. From private houses they took the atrium forecourt, and also the habit, which long prevailed, of adding to their churches subsidiary buildings, without consideration of the external disfigurement of the building by these additions."

Among the illustrations of interest in the book is that which we give as Fig. 2; a reproduction of a miniature in a manuscript dated 1088, giving a view of the Abbey of Saint-Riquier. M. Durand, in a monograph on the subject of this abbey, states that he has found proof that it was founded by the Abbot Angilbert in the year 800, and as this church was not demolished till the close of the eleventh century, we may presume that the illustration is an endeavour to represent the original church. The towers are no doubt of wood, and their prominence possibly throws some light on what may have been the appearance of some of the early Saxon cathedrals of England, a mediæval description of one of which conveys the impression of its having a large wooden tower with gilt ornaments. That some peculiarities of Saxon architecture find their counterparts, or perhaps their origin, on the Continent, is apparent from the design of the porch at Lorsch (Fig. 3), where we find the same straight-lined triangular wall-arches as are found in Saxon work in England. The original foundation of Lorsch dates from the end of the eighth century; M. de Lasteyrie gives reasons for doubting whether the porch as it stands is really part of the original building, which was almost entirely burned in 1090, but he thinks it probable that it is at any rate a re-erection of the original design. The interest of the illustration in Fig. 2, however, is not only that it gives an idea of a church of early date with a tower at each end of the nave, but it is a suggestion which might be carried out in a modern church design and produce a very fine and effective building; and if people of conservative ideas criticised such a treatment, in view of this ancient

illustration the architect might reply, in the words of Malvolio—"There's example for it."

The possibility of making more use of the square, or approximately square, plan in churches is suggested by the plans of some of the Romanesque churches of the Carolingian era, of which a curious and little-known example is given in the plan of the church of St. Satyrus at Milan (Fig. 4). In reference to this one cannot but regret that none of the plans given in the book have any scale attached to them; but that is unfortunately a common defect with French architectural publications. The plan has some resemblance to that of St. Mary Woolnoth, except that in the latter the columns are proportionately rather closer to the angles, and there are of course no side apses. But a fine modern church plan might be based on this idea, with the choir in the right and left spaces, and the organ in the apses behind them. A beautiful and most effective interior might be made out of this plan, of a Classic, Byzantine, or Renaissance type; it would not lend itself to Gothic treatment.

The possibility of roofing churches with a solid roof, both external and internal, instead of the stone vault with a timber covering over it, is constantly thrust upon one's attention in studying the sections of many of the early Romanesque churches. A cross-vault must necessarily have a timber roof over it (unless in these days we prefer a steel one), for its outer form is not such as could be made watertight, nor could it in any case be agreeable in appearance; the cross vault is essentially a roofing for internal effect only. Such a section as that of the church of St. Martial at Limoges (Fig. 5) is somewhat tantalising to look at; it seems so easy on such a section to render a church entirely monumental in structure; fill up over the arches with concrete and cover the whole with stone slates. Of course, in a sense, that might be said to be going back to an imperfect and primitive form of design. With the cross vault we have got the pressure of the vault confined to the salient points where the wall can be buttressed, and we can have as large windows as we like between. On the barrel vault principle, as used in the Romanesque period, the interior treatment is as shown in the view in St. Sernin Toulouse (Fig. 6), where the roof is apparently carried by a series of heavy transverse arches, one over each pier, with lighter shell between; but it is difficult to understand what structural motive the builders had in these separate heavy arches, as they do not take the weight of the intermediate parts of the barrel vault off the walls. They may, however, have had a structural use in this way, that they may have been the only portions built on a specially constructed strong centering, and a light centering of boards could then have been laid from one arch to the other, on which to build the intermediate portions of the vault. Beyond this, their structural function must have been an illusion; they made the roof look stronger, and carried up into it the main lines of the architectural substructure, that was all.

FIG. 3.—LORSCH ABBEY PORCH.

FIG. 4.—PLAN OF THE CHURCH OF ST. SATYRUS.
MILAN.

but the Romanesque builders nevertheless were so devoted to the heavy transverse arch that they persevered with it for some time after the quadripartite vault had come into use, when it was not only useless, but added an extra pressure upon the buttresses. It would be quite possible, however, with the assistance of ferro-concrete, or of steel joists, to make these transverse arches concentrate all the weight of the vault on the buttressed points, just as completely as with the quadripartite vault, by carrying the intermediate portions on steel joists bearing at each end on the main arches. But then there comes in the difficulty of lighting. In the section in Fig. 5, it is obvious that the upper part of the church must be very dark. It would be quite possible, however, to get over that by small lights under the eaves of the nave, and some larger ones in the upper storey of the aisles, without endangering the structure. There is the basis in that for a new attempt at a church with solid roofing

We have reproduced, as Fig. 7, the view of the interior of St. Georges de Boscherville, as one of the finest examples of the grand masonic style of the French Romanesque, with its solidly designed piers and round arches. Here the barrel vault has just been abandoned, and the quadripartite vault springs from the heavy wall-shafts. It does not quite look as if it belonged to the substructure; indeed, it is quite possible that there may have been some interval between the finish of the arcade and triforium and the

FIG. 5.—CHURCH OF ST. MARTIAL, LIMOGES: SECTION
THROUGH NAVE.

FIG. 6.—ST. SERVIN, TOULOUSE: NAVE ARCADE.

building of the vault; but the whole forms a grand and impressive piece of Transitional architecture.

The influence of the remains of Roman architecture on many of the details of the French Romanesque is most remarkable. At the very time that they were struggling with their new problem of vaulting, the builders seem to have been so strongly impressed with the remains of Roman architecture, which no doubt existed at that time in France in much greater profusion than at present, that they would introduce on the exterior of a tenth or eleventh century church a piece of almost pure Classic work. A remarkable instance of this is given in the illustration of part of the details of the porch of Notre-Dame-des-Doms at Avignon, on page 419 of M. de Lasteyrie's book. Here we have the Corinthian capital, the Classic cornice with carved modillions and egg-and-dart ornament, and the architrave with its three receding fascias, almost exactly reproduced, to decorate the entrance to a building which in its main design has nothing in common with Classic architecture. The doorway seems not infrequently, in architectural history, to have been made the opportunity for experiments not extended to the remainder of the building; thus we find so often in Elizabethan buildings the doorway framed within Classic columns and an entablature, though all the rest of the building is more Gothic than Classic. The difference is that in the Elizabethan building the Classic doorway is a move in advance, the taking up of what was regarded as the new style, while in the case of the French Romanesque churches it is a harking back to the remains of an earlier period.

M. de Lasteyrie's treatise includes a separate chapter on mural paintings of the Romanesque period, and another on the capitals. These latter, numbers of which are illustrated, form a most extraordinary collection in their variety of adaptations and variations from Classic and Byzantine forms, together with eccentricities of design which can be referred to no precedent, and seem merely the result of the desire for novel experiment. Many of the capitals of this class, it must be admitted, are more curious than beautiful—not an uncommon result, even in our own day, of the search after novelty merely for the sake of novelty.

At the close of his preface, the author expresses his hope to be able to produce a similar study of the churches of the complete Gothic period in France. We hope he will; his book could not fail to be of value. In the meantime, he adds, "I shall be satisfied if I have been able to interest my readers in our Romanesque architecture, to inspire them with the admiration for it which it merits, and thus to contribute in my modest way to protect these dear old stones from the dangers which threaten them." What exactly these dangers are the author does not say; but we are very much afraid that the chief danger to the ancient churches of France lies in the organised restorations carried on under the department of "Monuments Historiques."

The Roman Soldier and Roman Architecture.

MR. HALSEY RICARDO has something interesting to say on this subject in the April issue of THE ARCHITECTURAL REVIEW. He recalls the fact that, according to the Commentaries, war in the time of Cæsar was essentially a summer affair: when the days grew short both sides agreed to hibernate, and there was to be no resumption of hostilities until the spring should be well under way. The number of soldiers thus left in Gaul may, at an easy estimate, be put at 50,000, and the question was—what did they do with themselves during their enforced respite from fighting? It is clear that they must have been kept pretty actively employed, else they would have got out of hand, and we are not allowed to hear of any mutinies during the Emperor's absence. The principles of Roman construction supply the answer. The two salient and primary characteristics of Roman building are (a) that it can be done by unskilled labour under skilled direction, and (b) a kind of agonised ingenuity to be quit of the carpenter with his wood scaffoldings and timber centerings. In cantonments, then, building was done by

the soldier, with forced labour from the captives, and possibly also from impressed natives. It had to be done by men who were mainly stupid, largely unwilling, and to some degree malicious. These disabilities were kept in check and mastered by the superintendence of the officers and higher ranks of the soldiery, who plotted out the work to be done and supervised its execution. And the standard so set by the Roman army became the standard of construction at home as well as in the provinces, in the capital as well as in the military headquarters. The Roman centurion and master-builder could draw upon the artisans, the soldiers, the slaves, and the prisoners, to take part in the raising of stupendous walls, piers, and vaults; a few skilled men were needed to supervise the digging of the *pozzuolana*, to turn out the necessary large and small tiles, that played their various functions in the construction of these masses; to see that the army of hodmen deposited the stones, sherds, and brickbats evenly on the beds of cement mortar, that the mixers of this mortar tempered it with the proper quantity of water, and that the second army of hodmen carried this on to the building and properly grouted it in to the first army's deposit of stones. The thousands who composed these armies had only to do what they were told; the work was purely mechanical. We achieve the same result by machinery.

In the same issue of the REVIEW, Mr. W. H. Ward has an excellent article on "Rome under the Renaissance Popes," while Professor Lethaby and Mr. Harry Sirr both write about Inigo Jones. Other articles include "Jerusalem Doorways," by Mr. William Harvey; "Rock Gardens," by Mr. William Fitzherbert; and "The Planning of Delhi." Current architecture is represented by the International Bureau of American Republics, Washington (Messrs. Albert Kelsey and Paul P. Crét, architects), the Royal Academy of Music, Marylebone Road, London (Sir Ernest George and Alfred B. Yeates, architects), St. Wilfrid's Church, Kirkby-in-Ashfield (Mr. Louis Ambler, archi-

fect), and a three-light window for Bucklebury Church, near Reading (cartoon by Mr. Frank Brangwyn, glass by Mr. Silvester Sparrow).

Sir W. Richmond's Landscapes.

AT the Society of Fine Arts Gallery, there is a collection of small oil-paintings by Sir Wm. Richmond, of subjects in Italy, Greece, and Egypt, which are of considerable interest as presenting a new side of this artist's very varied talents. We have not hitherto known Sir W. Richmond as a landscape-painter, nor are these the kind of landscapes which are usually painted for exhibition; they are small oil studies of scenes which took the fancy of the artist, painted in the first instance, we may suppose, mainly to please himself and to carry away a record of an effective scene. There is a great deal of powerful originality about many of these small paintings; always there is the endeavour to convey the special character of the scene, as in "The Libyan Desert"; "Sunset, Girgenti"; "The Tiber," not in Rome, but out in the country; "The Convent Garden, Serpiolle," an especially good example. Architectural remains come into the programme, too; among others, a very effective view of the little temple of Niké Apteros seen between two of the large columns of the Propylæa which stand up on the foreground; and there are illustrations of the temple at Girgenti and of several Saracenic buildings in Cairo, Algiers, and Seville. It was quite worth while to exhibit these travelling studies in a collective form; they make an exhibition of more than usual interest.

Mr. Ralph Adams Cram.

MR. RALPH ADAMS CRAM, whose portrait we reproduce on this page, is a member of the firm of Cram, Goodhue, and Ferguson, now one of the leading combinations of architectural talent in America. Mr. Cram, who was born in 1863, is known principally as an architect; but he has also gained a considerable literary reputation by his writings on general and architectural subjects. He is a Fellow of the Boston Society of Architects and of the American Institute of Architects, of which he is chairman of the Committee on Education. He began to practise as an architect in 1889, and has since been jointly responsible with his partners for the production in the United States of a large amount of architectural work—ecclesiastical, secular, and miscellaneous, including the much-discussed Military Academy at West Point. Mr. Cram's literary work includes "Church Building" (1901), "The Ruined Abbeys of Great Britain" (1906), "Impressions of Japanese Architecture and the Allied Arts" (1906), and "The Gothic Quest" (1907).

The Awakening of London.

IN the "Report of the University College [London] Committee," which has just been issued, particulars are given of the recent developments in connection with the School of Architecture. It appears that the need for better accommodation for the School of Architecture has been prominently before the college authorities for many years, and that in view of this need, and also of the limited accommodation for architecture at King's College, the Senate appointed a committee to consider the organisation of architectural teaching. After receiving the report of the committee, the Senate decided, if and when funds were forthcoming for the provision of an adequate building, to combine the Schools of Architecture of University and King's Colleges in a building to be erected at the north-east end of the college site. In December, 1911, the money difficulty came to an end with the receipt of a letter from the Chancellor of the University (Lord Sebery) enclosing a "noble offer," from an anonymous donor, of £30,000 for the erection of buildings for a combined school of architecture, together with studios for the

MR RALPH ADAMS CRAM.

teaching of sculpture, the rearrangement of the School of Fine Art, and to accommodate the Department of Applied Statistics, including the Laboratory of Eugenics. This handsome gift, taken in conjunction with the more recently announced benefactions of more than £300,000 for London University, and of, we believe, about £40,000 for the new building for Bedford College for Women, would seem to indicate that London is at length wide awake to its responsibilities with regard to higher education; and it only remains to make the most of the magnificent architectural opportunities thus munificently provided.

New Buildings for Edinburgh.

THE example of London, or, perhaps, a correlative need for expansion, seems to have inspired Edinburgh with a desire for larger and more stately Government buildings. The Inland Revenue Offices in Waterloo Place are to be abandoned by that department, which will probably be accommodated in a large new block to be erected on some central site in the city. Provision must also be made for the new bodies set up by recent legislation—the National Insurance Act Commissioners, the Scottish Board of Agriculture, and the Scottish Land Court. It is said—with how much or how little authority we do not know—that a scheme is under consideration for the erection of "practically all the Government departments" in one vast building, and no doubt much could be said in favour of this idea. With respect to the internal economy, concentration is certainly a very commendable object; and, on an external view, it may be better to have one large and imposing building rather than several small ones. Yet the architect who should endeavour to carry out the principle or ideal of rendering a building expressive of its purpose would have some difficulty in reconciling such diverse functions. The Post Office authorities are to take over the Inland Revenue building, and they will also make large additions to the Telephone Exchange, extending the existing block in Rose Street by about one-third of its present size, at a cost of about £10,000. Building activity in Edinburgh in the near future will

receive a further much-needed impetus by the erection of five new schools, and by the extension of existing schools; upon which work the School Board contemplate an expenditure of £180,000. Moreover, as we have already announced in some detail in a recent issue, the Town Council are about to erect, in the Grassmarket, new headquarters for the City Police and for the Weights and Measures Departments—surely another problem in the hybridisation of buildings; while it seems quite likely that the scheme for laying-out the Calton Hill, and of building little or much upon or about it, will yet materialise. Altogether, the builders of Edinburgh, who know how to work nobly in a noble material, have in prospect an almost unexampled period of prosperity, which it is to be hoped may amply atone to them for the excessively lean years of recent experience; the Usher Hall, which is now assuming shape, being the only considerable building of public importance—except of course, Sir Robert Lorimer's beautiful Thistle Chapel at St. Giles's Cathedral—that has redeemed the industry from absolute stagnation.

Port of London Authority Preliminary Competition.

IN response to the competition announced in November last inviting the submission of preliminary sketch designs for new head offices for the Port of London Authority 170 designs were received. It was announced last Thursday that the Authority, on the advice of their assessor (Sir Aston Webb, R.A.), have selected the six designs sent in by the following architects, whose names are placed in alphabetical order:—

Mr. Robert Atkinson, A.R.I.B.A.

Messrs. J. A. Bowden and T. Wallis.

Mr. Edwin Cooper, F.R.I.B.A.

Messrs. Lanchester and Rickards, FF.R.I.B.A.

Mr. J. Reginald Truelove.

Mr. Ernest W. Wray.

The authors of these designs will be invited to take part in the final competition at an honorarium of 200 guineas each. The Authority do not propose to exercise the right they reserved to themselves of inviting designs from architects other than those who took part in the preliminary competition.

LIVERPOOL CATHEDRAL: DOORWAY FROM LADY CHAPEL TO VESTRIES. G. GILBERT SCOTT, ARCHITECT.

AN ADVERSE CRITICISM OF "NEO-GREC."*

BY ALAN L. SNOW, A.R.I.B.A.

The author contends that a purely Greek style is unfitted for modern requirements, and that the so-called "Neo-Grec" is not Greek in spirit or in form.

I SHALL endeavour to give you the arguments upon which I base two contentions. These are that a purely Greek style, with colonnades, pediments, etc., is absolutely unfitted for our uses and requirements, and that the manner of building at present known as "Neo-Grec" is not Greek at all, neither in the spirit of its design nor in the actuality of its appearance.

Most past styles, as they have been left to us, are in themselves unsuited to modern conditions in England, but of them all it seems to me that Greek is the most unsuitable. The charm of Greek buildings is in their shape as much as in their detail—in their long and low proportion. How can we transplant this into the tall modern building? We may maintain the same general proportion in the building, although its size is greatly increased. But it is too much to imagine that, by adopting in our larger edifices a similar treatment in detail to that which the Greeks gave to their smaller ones, we are perpetuating Greek architecture. We are doing nothing of the sort. Sometimes, perhaps, we may fitly use Greek forms for details, unless we can think of better; but even then they can only be used as a basis to work upon, not as a copy. We are doing quite wrong in increasing the size of the details as we increase that of the building; in enlarging things that were only meant to be small; in using them as our professed models the Greeks never used them, and in combining them with features which they either did not know or did not use. This reads like a summing up of the architectural fronts which the Romans applied to their buildings, and the case is indeed an exactly similar one. The attempt to adapt them leads to their entirely losing their Greek character. These new buildings of which we are so proud are Roman.

Greek architecture in England is joyless and cold—as cold as the Greek costume would be, and for the same reason. It was designed for a warmer, sunnier land. That this is felt even by those who attempt to practise it seems to be indicated by the way in which it becomes embellished. I was going to say enriched, but "embellished" seems somehow better to express the result that we see. In this embellishment, and in the increase of scale already referred to, its Greek character disappears. The simplicity of Greek is gone, and in its place is richness and extravagance; the architecture has become Romanised. We are doing just what the Romans did; we have turned our Philistine minds to Greek architecture, and produced a manner as far in spirit, proportion, and character from its beautiful inspiration as it could be.

Modern requirements of speed in erection have brought about a certain adaptability of one pattern to all positions quite unlike Greek, in which each small part received separate careful consideration. The Florentine Palaces, thirteenth-century Gothic, or a Cotswold cottage are more truly Greek than these modern street buildings.

Something very like these examples would have been produced by the Greek architects, given the same conditions and the same materials. Something of what they would do when faced by new needs and circumstances Byzantine architecture shows. With a new religion and a new social system, requiring different planning, and a new material—brick—they evolved a new architecture, from which the column and pediment, the console and the cornice, and many other features considered indispensable by Neo-Grecs, were conspicuous by their absence.

The complete absence externally of such features as these, in the imposing mosques which are but a development of the Byzantine style, shows how inessential they really are to architectural beauty, the secret of which lies in something higher than the mere manipulation and adaptation of such forms. Is not the Taj Mahal acknowledged to be one of the most beautiful buildings in the world? Yet none more opposed to Neo-Grec tenets can be imagined! In India, if anywhere, Greek would look its best; but there is at least one building there as beautiful as the Parthenon itself, and yet absolutely opposed to it, in its construction and in every detail. Cannot we attain to some such measure of architectural independence?

What is the distinguishing characteristic of this great Greek style? Is it not simplicity—a simplicity possible only because of the small size of even their greatest buildings? It is simple, too, because they adhered to one method only of building, and developed that until it could go no farther. This they were only enabled to do by a corresponding simplicity in their life and the problems of their architecture. Indeed, there were no problems in those days compared to those which face a modern architect. Their architecture goes but a very little way in helping to solve these, for it was so simple that we can use it in connection with only one feature—the pier. The Greeks evolved two forms of pier—circular and square, always used separately and each with its own distinct function. One of the most prominent characteristics of the Neo-Grec manner is the use of the circular pier stuck on to the square, the reasonableness of which proceeding will not bear examination. Neither will an enquiry into its beauty, to my mind. Whatever may be urged in its favour, it is not Greek; nothing further from the straightforward, logical architecture of the Greeks can be imagined. It is all of a piece with broken entablatures, curved pediments, and "suchlike contraptions."

Not only is it not Greek in form, but neither is it in spirit. No modern building, carried out in a purely academic Greek manner, using only Greek details and features, is so. Greek art itself would have been different in a different environment. Had we learnt truly the lessons of their architecture, we should never indulge in this literal, uncomprehending transcription of their style. We should not ignore all that has happened since—they did not. They did not invent an original architecture all their own. They too studied the past, and their understanding of study was the correct one—

the selection and perfection of certain features. Study means selection. They selected one method of construction—not one *manner of design*—and throughout all the variations of it which they used, it is never obscured; and the refinement and ornamentation which the crude essentials of this method underwent were all directed to the emphasising of the functions of the various parts—the vertical lines of the columns, the horizontal ones of the architrave, and the projections of the cornice. They evolved an *order* of building, and only by a strict adherence to this was possible the perfection they achieved.

By a close and never-ceasing study of construction they developed their beautiful architecture, as perfect a style as the world has seen, but not so perfect as to be universally applicable.

The Greeks were able to pursue the study of one particular manner of building, and bring it to its very simple perfection, only by the comparative isolation of their land and the extreme simplicity of their life.

We can never return to the old Greek dependence on the most elementary of all forms of building construction. We cannot get away from the fact that we know more than did the Greeks, in every department of human knowledge. We may not be wiser, but we know more, and we might attain to equal wisdom by study and understanding of what we know.

For the modern man, Greek is the beginning of architecture, and it is absurd to ask him to go back now to the beginning, to ignore all that has been achieved in the past 2,000 years. It is true that we must study the past; thus was produced Greek itself; from the study of Greek and Roman was evolved Byzantine, and from the latter Gothic—buildings which, in their time, were absolutely new and modern—but rooted deep in the past, for all that. They came into being by the application of past lessons to present needs and materials; they were the result of experimental design. What could we not produce by the critical study of past problems and their solutions, of the triumphs and failures of the past, with a concurrent study of engineering in steel and concrete—the study of our modern needs and modern materials? Have not all great arts and sciences developed along the lines of critical research, comparison, and experiment? What stimulus is there to equal that derived from the knowledge that one has mastered the secrets of the manipulation of the vast forces at one's disposal? What is more likely to lead the keen modern mind to fresh discoveries, to achievements worthy to rank with the great architectural inventions of the Romans, the Byzantines, and the Middle Ages?

The greatest legacy that the Greeks have left us is their recognition of the æsthetic element in construction, and since their days the great successes of architecture have been due to great engineering. The Romans were great architects entirely because they were great engineers; there is little of real beauty in their buildings, but they are supremely wonderful, and wonder is one of the elements of fine architecture. We wonder at Greek perfection and at Roman engineering, and at that combination of the two that we call Byzantine. The men of the Middle Ages were great architects, too, by virtue of their skill and daring in building; in the successful engineering of their materials.

*Extracts from a paper read at the Architectural Association. Camera, Sketch, and Debating Club, on March 14th.

It is most important to note that all of these great styles of architecture arose through continual *experiment*; therein lay their life. Renaissance itself was a living art so long as it remained true to experimental construction. Immediately it was assumed that this had reached its final stage, that the last word had been spoken, architecture then became academic, and merely a matter of adaptation. All life and joy departed from it.

In Greek and Roman, in Gothic and Byzantine, supreme art accompanied supreme construction. We shall see that this must be so, as the perfect craftsmanship and clear vision that are necessary to achieve greatness in art are the very qualities also necessary to achieve greatness in construction. All great architects have been great constructors right down to our own times. Perhaps our apparent unwillingness to recognise this fact, and appreciate its great significance, is due to the suggestion of platitude that there is about it. If it is platitude, however, it is because it is truth, and therefore precious, so few are the determinable truths of architectural ethics. To it is due the feeling that comes to us when contemplating the great monuments of the past, a feeling that they are inevitably what they are—that they took the shapes they did, not through the conscious caprice of their builders, but through the force of circumstances beyond their control. They were as much the product of their age and circumstance as were the feudal system, party politics, or the steam locomotive of theirs. It is from this feeling—that as they are so *must* they have been—that we derive the satisfaction and

contentment that is ours in their contemplation. We view with equal pleasure the Parthenon, the Pantheon, or Notre Dame, unless we are architectural bigots, and to these I may add the Forth Bridge and the Gare d'Orléans—classic instances by now.

In short, these great buildings are not merely beautiful—they are significant. They have a meaning and a beauty apart from the decorative forms in which they are clothed, forms in themselves accidental. It is this significance that raises them to the highest plane as artistic achievements.

It was by the arrangement of their essential constructive forms to secure the greatest convenience, economy, and strength that they obtained their splendid results—by what we understand as planning, and the adherence, in the design, to an *orderly* and logical arrangement of the constructive parts never departed from, and never allowed to become obscured by the ornament. Through it the buildings assumed their external beauty more or less unconsciously; certainly it was not deliberately regarded as the principal consideration.

It is here that the present Neo-Grec style fails completely, and can therefore never be regarded as being the best that we can do, and can never attain the same plane as the great architectures of the past.

External beauty is dependent upon many other things than mere form. Something that has been self-consciously designed, something that we feel to have arisen because its author considered it would look "nice" carried out in that

manner, we somehow are not completely satisfied with. In the case of a city hall or a parish church masquerading as a Greek temple, it is its insincerity that repels. As we cannot be Greek in our lives by wearing Greek dress and adopting Greek furniture, so we cannot have Greek architecture. It is *nothing* here; it has no meaning, and is neither Greek nor English.

Is architecture going to stand alone? Is our modern style to be the first of all to separate itself from the intellectual life of the age? Or are we going to be Neo-Grec in all our arts? An art that has anything in it should permeate the whole artistic life of the nation.

Art is thus reflected in all the life of ancient Greece, and in Roman, Gothic, and even Renaissance. Cannot we all identify the smallest thing dating from any of these periods? Are we to mount even higher on our pedestals, from which Mr. Burns, recently and quite justifiably, besought us to descend?

St. George's Hall, a unique building, was brought into being by a unique problem, and it, and other similar buildings, are no argument either for or against a general adoption of the style, any more than that other unique building, the new Liverpool Cathedral, is in itself a justification for the condemnation or universal adoption of Gothic.

The only real argument for the adoption of Greek would be that its forms could be arranged so as to obtain qualities otherwise impossible of achievement. Apart from the fact that argument of this character places architecture no higher than scene-painting or mural decoration, it is certainly not the case; it could not be so in an art such as architecture.

THE CATHEDRAL, HAARLEM, HOLLAND: VIEW FROM THE SOUTHEAST.

THE GREAT STATE MUSEUM, AMSTERDAM.

any more than in music. With the fundamental principles of design, and their application, as a basis for criticism, the same abstract qualities can be traced in any style of architecture, quite independent of the particular forms in which it may be clothed. But fine architecture has another set of principles to which it *must* adhere—fitness to purpose, climate, and other conditions peculiar to each country. With these as our guide, all that can be urged for Greek in England can be urged for any other style—it becomes merely a matter of personal predilection, and not of principles at all.

There is no more reason for using Greek than English Gothic; not as much, indeed, for the latter, which was many centuries in coming to perfection, is distinctly English, is suited to the climate, is supremely beautiful, and can be absolutely fitted to modern conditions. Any arguments against it are equally applicable to Greek, and many of those for it are not. I am not arguing that Gothic is *the* style for us, but to my mind if it can be made to meet modern requirements as well as the Greek, the argument that in it we have a carefully developed national style of our own is the one that turns the scale in its favour.

We may feel, from the study of Greek, that all other architecture is incompletely worked out; but why not work it out? Why not attempt something? Might we not find that we too had produced something worth while? Or are we just to take the easy road—to quiet our architectural conscience (there *is* such a thing), and steal and borrow our architectural forms; stifle our architectural intellect, and kill originality of thought? "There is no substitute for thought."

Every reference to the past should increase the mental labour of the enquirer, not serve as another modern labour-saving device, as it so generally does. He must endeavour to find out why each feature that he examines is as he finds it; discover its purpose, and determine its suitability both for that and the one that he proposes to put it to. By such methods it should be possible to build up a satisfactory philosophy or *order* of architectural design. By so doing we should arrive at a method of building beautifully that would be truly Greek in spirit—of which the plans and constructive forms would be absolutely modern, but nevertheless profoundly influenced by past achievements. In it we

might well find that many of the details were based on Greek forms, simply because certain features were so well studied by the Greeks, and brought by them to such perfection, that we are hardly likely to be able to improve them. Such a modern style would include not only the post-and-lintel system of building, which is all that the Greeks bequeathed to us, and which alone is far too small an equipment for our requirements, but also the round and pointed arch, the vault, and the dome. In it would be found no place for such incongruities as the circular pier sunk into a square one, or a colonnade standing a few inches only from the real wall of the building, carrying nothing but a balustrade and a few urns! Nor should we find a huge order, with its own entablature, surmounted by a low attic with a very much larger one, itself concealing a range of windows or merely forming a parapet wall, 10 ft. or more in height! Circular columns would be used only when detached, and only then when actually supporting something, under which circumstance alone do they find their true beauty. We may be certain that abundant opportunity would be found for the use of so lovely a feature.

Steel would come into its own, and its

possibilities be recognised—the qualities of the square wall pier be seen, and taken advantage of.

To me the most exasperating thing about these buildings of the latest Greek revival is the almost complete neglect of the splendid opportunities that await the truly modern architect. Can we do *nothing* with these? Must we fall back on engineers for our construction and the Romans for our clothing of it? Have we no wit or imagination?

It is the great fault of the average architect that he does not take advantage of his opportunities as an artist. That is, he does not set out to *create* something, but at the first opportunity harks back to what someone else has done. How can his art improve if he accepts the conclusion that the best has been done, that there is nothing left for him to do but adopt and adapt the ideas of other men? If I really thought this, I would never have become an architect. To be so hide-bound and fettered would be intolerable. We are not free to do as we like—far from it—but there is no need to so imprison our intellects. That is what seems to me most missing in modern English architecture—intellect—the mental grappling with and overcoming of our problems.

CHURCHES AT HAARLEM AND THE HAGUE.

These churches are notable examples of the work of Dr. Cuypers and his firm, whose name has so long been prominent in the annals of the Gothic Revival in Holland. The interior of St. James's Church at the Hague, though not ranking among the largest, is, in its forms and decoration, typical of the many parochial churches designed by Dr. Cuypers. The still incomplete Cathedral of Haarlem is the architect's most important church work, and one of the more recent. It shows something of an experimental quality, although to a large extent the Romanesque strain disappears in the interior, which is of an early and severe type of Gothic, yet not free from novelties. Like the generality of Dutch churches, ancient and modern, both these examples are built mainly of brick, as also is the great State Museum at Amsterdam, shown on this page.

W. R.

ST. JAMES'S CHURCH, THE HAGUE: GENERAL VIEW OF INTERIOR.

PLANNING ART MUSEUMS AND PICTURE GALLERIES.*

BY EDWIN T. HALL, F.R.I.B.A.

THE conception of museums in general is too wide for discussion here. Let us consider the main lines and general principles on which an art museum should be designed. First of all, its entrances and exits. It is not desirable to have more than one door (or group of adjacent doors) both for the ingress and egress of people in normal circumstances, so that all may be under observation by the same attendants. Fire-escape exits in a large building may be necessary, but these should be safeguarded. The common ingress and egress facilitates the placing of cloak-rooms. A spacious vestibule or hall will of course be necessary, and should be consonant with the dignity of the place.

Assuming a large building on more than one floor, the main staircase should be conveniently near the entrance, so that visitors to departments upstairs may at once be separated from those to the lower departments, thus reducing or disseminating the volume of people. I have seen designs where the main staircase is at the end, opposite to and far distant from the entrance, so that visitors who come especially to visit the upper floor have to pass through the lower, to their own inconvenience and that of those in contemplation of the ground-floor exhibits.

Details of Planning.

In a relatively small building a very usual plan is a rectangle with a central court, the staircase being in the centre or at the entrance, and this arrangement is commended by most authorities. At Cologne we get a central court, the stairs being right and left of the hall. In medium-sized buildings, such as at Münster, the Kunst Gewerbe at Berlin, and at Brunswick, we have an expansion of the same idea. The administration offices should, again, be placed in a position convenient for those who have merely business relations with the museum, so that these may not interfere with the art visitors. Such necessities as refreshment-rooms, etc., may be placed where convenient for general access, but it must be remembered that the supplies and staff should have access without having to pass through the galleries.

Top-lighted galleries may be placed in internal courts with rooms around them, or they may be on the top floor. The latter position is preferable for many reasons, one of which is that if the central gallery has a roof at the height of the surrounding building, this will be quite unsuitable for anything but sculpture or architecture; and if the roof be kept down the shadow from adjacent buildings will be objectionable.

Courtyards.

There is a widespread view among directors that there should be internal open courtyards to museums, and Dr. Gustaav E. Pazaurek, the director of the museum at Reichenberg, in 1903 said: "The internal courtyards of a museum should be laid out as gardens in which should be sculpture meant for outdoors." You will, of course, call to mind many sculpture gardens in Rome, Florence, and many other parts of Italy. In the Welsh National Museum at Cardiff, Messrs. Smith and Brewer have this feature with

a central fountain, and below the courtyard is an aquarium. They have also, in the external garden, an open pavilion for the display of national dances, for open-air concerts, etc., a feature highly to be commended. It is objected by some that our climate does not suit open courtyards for sculpture, etc., but the objection could be met by a plain glass roof with open sides, converting the courtyard into a covered garden. This courtyard feature is one to be encouraged and developed, and although we cannot have such large spaces as the Italian courts and gardens, or even the Grand Cour du Louvre at Paris, we could frequently have them of areas larger than the Octagon Court of the Vatican, which is but twenty metres across. In any case, these open courtyards enable excellent light to be obtained for lower galleries and basement rooms. The exigencies of the exhibits may require the windows of one room to be varied from those of its neighbour, or may demand, perhaps, a different architectural style for the window. This, in an internal area, can be done, but if the same were desired on the external facade of the building, it would be difficult to do it without damaging the architectural unity of the composition.

Sculpture Galleries.

This suggestion of sculpture in gardens brings us to the consideration of sculpture galleries themselves. There is considerable difference of opinion as to the best means of displaying sculpture. Some authorities favour large courts or galleries with plain glass roofs all over the area—in fact, the nearest approach to the open air; others say sculpture is best displayed by light coming from windows placed high up near the ceiling, the sculpture being placed near the opposite wall, so that light may come diagonally to it. There is much to be said for both views, but the open court view is more on all fours with the covered garden, and should be only for large groups such as Italians would put into their gardens. The latter view is more applicable for cabinet sculpture. If the area be large and the sculpture-groups well placed, the open top light is perhaps best on the whole. A well-known example is the Luxembourg Gallery, 130 ft. by 40 ft., which is top lighted for nearly its whole length. There, no marked light or shade is noticeable, except that in the central parts the vertical light is too great. If the area be small and in the nature of a long gallery there is danger of the shadows from brows, nose, ears, and chin being too much accentuated. All will call to mind the excellent light from high lunettes and windows in the Vatican corridors, and notably in the alcoves of the octagon court of the Belvedere. I think one of the finest architectural schemes for the display of sculpture is a wide colonnade (either straight or segmental on plan) at the ends of the central courtyard.

Alcoves.

Another important feature is to form alcoves in the gallery so that statues or groups may be isolated and attention concentrated. Of course, in considering sculpture galleries, regard must be had to the ready accessibility for heavy masses to be brought in from outside, and a basement road access is necessary for carts. Then important works and inferior works

must be separated, but the latter may be in near rooms for contrast or comparison. This is a point which has to be settled before an architect can mature a plan for sculpture galleries.

Laying out New Galleries.

We now come to the general disposition of other galleries in a museum. What is to be the principle on which they are to be laid out? Are galleries for all the different exhibits on a floor to be in one range; that is, to open into one another so that a visitor shall pass through all and make a circular tour back to his starting place? Are galleries to be in groups so that each group shall take one branch of art and illustrate it through all time? Should art work of all kinds of each period or era be illustrated together in the same room or gallery? For the convenience of administration and supervision only, the one continuous range is better. Large numbers of people are passing in only one direction, and do not interfere with those following them. On the other hand, if a visitor wants to contemplate one period of art—be it painting or any other manifestation—he has to make the other rooms mere passages.

In small museums or galleries the question we are considering settles itself. The floor area is limited, and the galleries on any one floor become a manageable unit which, if well arranged, meets with general acceptance. It would appear to be possible to apply this small unit principle to a museum of any dimensions, however large.

With respect to the ordinary galleries the general feeling in respect of all except picture galleries is that side-lighted rooms are best. Show cases having shelves will be better lighted from the side than from the top. In the former case the light passes between the shelves; in the latter one shelf casts a shadow on that beneath. For efficient lighting in our northern clime, cases should not be placed more than, say, 20 ft. to 25 ft. from a window. Windows in our climate should be kept as close to the ceiling as possible so as to get the highest possible angle of light, and in order to get the valuable reflected or diffused light from the ceiling surface. Show-cases should be placed with the long axis perpendicular to the window.

A good height for the window-sill of side-lighted rooms is 7 ft. 6 in. above the floor.

Colour of Walls.

As to the colour of walls there is a great difference of opinion. Nearly all agree that the background for pictures should be dark. I think it may be safely said that a background is successful in inverse proportion to its obtrusiveness. At the Royal Museum of old paintings at Brussels some backgrounds are of plush. some of velvet, the colours of different rooms being sage-green, Indian-red, and old-gold. In the Musée Moderne of the same city plush and cloth are used of Indian-red colour. In the new rooms of the London National Gallery the colours vary; some are green, some golden bronze, others red. Many artists favour red, but probably the colour scheme of every room in any permanent gallery can only be settled by adapting it to the pictures which are to be hung. One artist of great experience in hanging is of opinion that a bright background suits an Old Master better than it would a modern picture.

Reserve Galleries.

An important feature of a museum is the reserve galleries. They are not mere

*Extracts from a paper read before the Royal Institute of British Architects on April 1st.

THE MAYNARD ARMS HOTEL, BOGWORTH, LEICESTER, EVERARD, SON, AND PICK, ARCHITECTS.

This hotel is constructed with cement-faced brickwork, the roofs being of old Leicestershire Swithland slates.

warehouses or store-rooms. Some may be so used, and these should be near the goods entrance, but the main purpose, according to modern ideas, is that they shall be accessory to the exhibition galleries, and that from time to time the exhibits proper in the galleries shall be changed so as to keep up public interest. For this purpose the reserve galleries should be adjacent to the other galleries to facilitate ready exchange of objects. There should be students' research and copying rooms off each department, where students may be quiet. Each department should have for its keeper a room, well lighted and quiet, and convenient of access for visitors and students. This gentleman is an important official, an expert responsible for his department, a referee and lecturer, although I have seen designs in which the authors appear to have thought he was a porter.

The children's room is a modern adjunct, and it should be near the entrance.

A department should be set aside to illustrate by sketches, drawings, and models—in some cases actual size—the archaeology of the district, the demolished streets and old-world buildings.

Lecture Theatre.

Last of all the public rooms is a lecture theatre, and this should be so arranged that, while it is accessible from the museum, it may be separately entered from the outside so that it may be used when the museum is closed. It requires its separate cloak-rooms, lavatories, exits, etc. Its form depends on circumstances. In some cases its use may be restricted to lectures, in which case a semicircular form is convenient, with tiers of seats. In other cases it may be adapted for other uses as well, as, for example, for photographic or microscopic exhibitions, in which case it is better to make it rectangular with a level floor.

Last of a long series of slides, Mr. Hall showed the British Museum as it is proposed to be when completed. The old part was erected in 1855. The northern block of galleries is approaching completion, and it was seen that the ultimate extension will reach to Bedford Square on the west and to Montague Street on the east. The well-known reading-room is in the centre. The new galleries on the ground floor and first floors will be 48 ft. wide, lighted from both sides. Those on the top floor are skylighted. They are 19 ft. high to the base of the coves, and 30 ft. high to the lowest edge of the glass in skylight. This building, when finished, will, the lecturer said, form the noblest architectural monument of the Metropolis.

DISCUSSION.

Dr. Evans Hoyle, of the Welsh National Museum, proposing a vote of thanks, emphasised the necessity for the division of museum collections into two separate parts—namely, for the general public and for the student and specialist, for whom reserved galleries should be provided. With respect to pictures, no one background had been found to be better than another; backgrounds should be selected to suit the objects placed upon them. The speaker then referred at some length to the museum at Munich, which had been specially designed to contain a collection representing the art history of the city up to the middle of the nineteenth century. Every room was definitely constructed for the particular class of object it was to contain. To adopt this principle generally would of course

prove fatal. Its great disadvantage was that the museum was complete, and if it was desired to record any subsequent period a new museum would have to be built. At the National Museum of Wales, he continued, they had avoided the mistakes of their predecessors. For instance, the administration rooms had been put on the second floor. The director's room should not be too accessible to the public, and for obvious reasons it should be provided with two doors. With respect to lighting, for gallery pictures, the top-light was the most satisfactory if not too vertical. If a gallery were side-lighted, the walls that join with those containing the windows should be splayed and not at right-angles.

Sir W. Goscombe John, R.A., seconding the vote of thanks, said it seemed to him that the difficulty was to bring into line the interests of the dilettante person and those of the student. Referring to museums, he thought they should be kept as small as possible, otherwise, to avoid the distraction of a multiplicity of objects, one would have to be led with blinkers on to whatever one wanted to see.

Mr. Frank Dicksee, R.A., agreed with Mr. Hall that top-lighting was most satisfactory for picture galleries. With regard to backgrounds, if it were necessary to choose only one colour, he thought that grey was most desirable—at any rate for modern pictures. Architects, he thought, in designing picture galleries, concerned themselves more with the architecture than with making adequate provision for the exhibition of pictures, although this really was the purpose which the building had to serve. Galleries should not be too lofty; and pictures should be kept reasonably low on the wall. Mr. Dicksee concluded by criticising the hanging of the portraits of past-presidents of the Institute. The pictures, he said, were much too high.

Mr. William Woodward said it was curious that the architect, when designing a picture gallery, seemed to delight in making merely an architectural building, without any consideration for the purposes to which it had to be put. No reference had been made to the Tate Gallery, which, in his opinion, was one of the best-lighted galleries in Europe.

Mr. H. H. Statham said it appeared that the best method of lighting a gallery was by a lantern with vertical lights, the centre part being opaque. The Palais des Beaux-Arts was a good example, the quality of the light obtained being almost equal to daylight. This building was also admirable for the exhibition of sculpture, there being plenty of space for setting-out and ample room to get round the exhibits. Mr. Statham then suggested the roofing-over of the courtyard of the Royal Academy and the exhibition of the sculpture there. With regard to the hanging of pictures, to which a member of the Royal Academy had referred, he knew of painters who complained that at a certain place their pictures were hung too high.

Mr. Arthur T. Bolton protested against the planning of galleries in a series of small rooms. Before we allowed the specialist to run away with our public galleries, it should be pointed out that architectural effect was just as desirable as accommodation for students. He disagreed with Mr. Woodward; the Tate Gallery, he thought, was the worst-lighted gallery he knew. His personal

preference in the lighting of galleries was for flat glass roofs, of which he had recently seen a remarkably good example at Birmingham.

Mr. Matt Garbutt said that glazed pictures were often nothing more than a looking-glass. He suggested the placing of screens at the back of spectators.

Mr. Ernest Newton, who occupied the chair, in putting the vote of thanks, said that as architects they could only have one view—that fine art must be finely housed. Practical purposes must, of course, be considered; if a building failed in its practical objects it failed as a piece of architecture.

Mr. Edwin T. Hall then briefly replied. He could not assent to Mr. Garbutt's suggestion with reference to the provision of screens, which, he thought, would spoil the appearance of the room, as well as an obstruction to visitors.

LEGAL.

Builder's "Third Party" Liability.

In the Court of Appeal on Monday of last week, Lords Justices Vaughan Williams, Farwell, and Kennedy heard the application by the defendants in *Jackson v. London County Council and Chappell*, for judgment or a new trial in an action tried before Mr. Justice Bray and a common jury, in which plaintiff, who was a boy between 13 and 14 years of age, claimed to recover damages for personal injuries sustained owing to the alleged negligence of the defendants or their servants. Mr. Chappell was a builder and contractor, who was employed in January, 1911, by the London County Council to carry out certain repairs to a school in Middle Row, Kensal Road, London. On January 7th Mr. Chappell sent a truck containing the materials necessary to do the repairs to the school. The materials consisted mainly of rough stuff, composed of four parts of sand and one part of lime with a little hair. The truck and its contents were left, at the suggestion of the caretaker of the school, in the corner of the boys' playground. The school reopened on Monday, January 9th, and the headmaster of the school on his arrival noticed the truck and gave instructions to the caretaker to have it removed, as he considered it was dangerous, and the caretaker telephoned to Mr. Chappell asking him to remove it. He sent a man, who, however, did not do anything. At the close of the afternoon school, as the boys were leaving, the truck was tipped up and the contents emptied out, and some boys played a game of "snowball" with the rough stuff, making it into balls for that purpose. One of the boys threw a ball and hit the plaintiff in the eye, injuring the sight of the eye. The jury found £50 damages against both defendants, of which they apportioned £25 against each defendant. The defendants then appealed. The Court, without calling upon counsel for the plaintiff, dismissed the appeal, Lord Justice Vaughan Williams, in the course of his judgment, saying that the evidence had shown that the schoolmaster had recognised this barrow as a source of danger, while with regard to the contractor it was clear from the evidence that he was told to take some steps to remove the barrow, but that he had not acted sufficiently. In his judgment, this appeal failed and ought to be dismissed. Lords Justices Farwell and Kennedy agreed in the judgment of Lord Justice Vaughan Williams.

MR. DONN BARBER ON THE
ETHICS OF COMPETITIONS.

In America, as in this country, discussion of the competition question is perennial. From Mr. Barber's observations, which were delivered at the forty-fifth annual convention of the American Institute of Architects, it would appear that the practice of inviting competitive designs for private work is much more common in America than, happily, it is in this country, and that it is in the case of the private owner that the system is most gravely abused.

Competitions in one form or other, says Mr. Barber, are as old as the practice of architecture itself, and history teaches us that the resulting heart-burnings and disappointments, the strife and argument, the petty jealousies, the very important doubt as to whether after all the best man and the best plan have really won, obtained as much in the competition for St. Peter's at Rome as it has perhaps in our lesser competitions for a building of negligible importance.

It would be improper and unfair, indeed, to condemn competitions as a whole and indiscriminately, for from some points of view they seem to be a necessary evil. We can, I think, admit that competitions in themselves are not necessarily evil. The evil arises from the abuse and mismanagement of competitions, the unbusinesslike, undignified, inadvised, desperate sort of struggles that ever carry in their train disappointment, prejudice, criticism, and hard feelings of many and varied kinds. All this is responsible for a condition that has become a most serious consideration in contemplation of the inter-relation of architects, and bearing upon the actual work that we as a profession are doing and standing for. The architectural profession has for years been kept in a state of commotion, while the real solution of the difficulty seems as yet unfound.

It seems to have become a very generally accepted and recognised tradition in certain cases, notably where proposed structures of a public or semi-public nature are involved, that architectural competitions still prove to be desirable or necessary as furnishing, perhaps, the best available means for selecting an architect. Just at the present time in America, however, architectural competitions seem to be declining in popularity. Where only a comparatively few years ago competitions were sufficiently numerous to provide almost continuous employment for some firms who were fortunate enough to acquire the major part of their work in that manner, to-day we find an immense quantity of important work being given out by direct selection and appointment, and competitions comparatively infrequent. It would be difficult to assign any real reason for the change which seems just now to be taking place. Can it be that the owner is gradually coming to see that competitions are at best very slow, and, if properly conducted, are a most expensive method of choosing an architect? Is it possible that the owner realises that an occasional good preliminary scheme is, after all, the real limit of the competition method, and that being the case, competitions are in the main of no advantage to him? Does the owner begin to appreciate the extreme difficulty of devising a scheme of competition that will afford him conclusive assurance and evidence of the winner's ability to secure for him the final and practical execution of the design selected,

without committing him to unnecessary, if not inordinate, expense?

Notable instances exist where architects who have proved adepts in the preparation of competitive designs, men of extraordinarily developed imagination and possessing marvellous dexterity in draughtsmanship, have been awarded the prize, and later the work, as a result of competition, and have during the prosecution of the work shown themselves to be devoid of practical experience, and even lacking in the ability to discriminate in the selection of competent assistants or superintendents? The ultimate results in such cases have probably had the very, natural effect of somewhat impairing confidence in the competition method of selecting an architect. It is only fair to say, on the other hand, that there also exist many instances where notably satisfactory results have been obtained through the method of competition; but have these not ordinarily followed as a result of choosing the competitors from the ranks of competent and thoroughly experienced practitioners, and paying the competitors so selected an adequate or reasonable sum for their sketches? Exceptions to this latter rule might be noted in the cases of government and municipal work, and perhaps, possibly, in some private work of sufficient size and importance to induce the experienced architect to enter an unpaid contest; but even under such circumstances the competitors have usually been limited in number and carefully selected.

It must of necessity be prejudicial to the interests of the owner that any architect should be allowed to enter a competition who cannot in advance establish his ability and competence properly to design and satisfactorily execute the work involved. It is sometimes urged that to open an unlimited competition may disclose some unknown but brilliant designer. This reasoning might be valid if the sole object of a competition were to secure a brilliant set of sketches. But unfortunately sketches in themselves give no real evidence that their author has the technical knowledge or matured ability to fulfil the promise of his sketches through proper and adequate control of the work itself in execution.

The general influence of competitions can for present purposes be broadly divided as regards the influence on the architect. Theory presupposes competitions to be instituted with the sole purpose of advancing the interests of the owner, and practice proves that these interests are best served where a fair, clean-cut, and equitable agreement has been entered into between the owner and the architect before the competition takes place.

The American Institute of Architects, after years of untiring study and labour, has finally issued a circular of advice relative to the conduct of architectural competitions, as a statement of the principles which it believes should underlie such agreements. Serious difficulty with the system prescribed, however, has been found in some cases where it has proved inexpedient, not to say impossible, to carry on important competitions along the lines of what is conceded and believed to be the best practice, owing to the general and natural desire on the part of the owner to get free advice in the form of the greatest possible number of competition sketches, and also on account of the surprising willingness on the part of the architect to rush into competitions where no prearranged agreement or

understanding exists with the owner. The owner often regards what he believes to be the information contained and given in his particular competition in the light of a consensus of expert opinion on the subject of the problem before him, and therefore is pleased or disappointed, as the case may be, with what he regards to be the possibilities of his project. On account of the quality and character of the information so given, the real satisfactory solution of the problem is often complicated, and confusion rather than lucidity results. We have all seen the results of what have been termed "unregulated scrambles," and how many times this inconsistent, unbusinesslike, undignified, and certainly inartistic mode of procedure has carried with it its own disappointments, prejudices, and sins.

Why an owner, even when he has taste and judgment and is besides a good business man possessing ordinarily sound common sense, continues to persist in this method of obtaining a design for a building, is a question which architects must answer. It is certainly a most discouraging situation, looking at it entirely unselfishly and from a directly professional standpoint.

Architects are not paid enough for the work they actually do to be able to afford to waste their earnings on the whims and fancies of an owner who is willing to take without compensation from them, in one form or another, professional advice which may be the result of years of technical preparation and experience. The public should be made to feel that he who bears the title of architect has the knowledge and ability needed for the proper invention, illustration, and supervision of all building operations which may be entrusted to him, and that his services, when desired or sought, are entitled to commensurate remuneration. An architect should have a better standing in the community; he should be more prominent before the public and its public enterprises, in the courts and in all matters of good and helpful citizenship. To just how much of the lack of all this can we trace the influence and practice of unlimited and irregular competitions obtaining throughout the past is a question well worth considering.

The influence of competitions on the architect, aside from the undoubted educational advantage which they have furnished at unjustifiable and exorbitant expense to the profession, has been to create unreasonable jealousy and unfair prejudice, misunderstandings, disappointments, and in many cases undeserved criticism. It must be remembered in competitions that the resulting joy, if there is any, is of necessity confined to the winner, while the burden of disappointment is left to be shared by all the others who have competed through labour and expense. It has been proved over and over again, as an economic argument in the case of competitions for smaller buildings, that the unsuccessful competitors have often expended collectively in the cost of preparing competitive designs, a sum equal to, if not exceeding, the gross fee that the successful architect has finally received for his complete services rendered in connection with the execution of the work involved. This is, of course, a serious situation for the profession, and one which thus far has not been properly met or handled. It cannot be justified either as a good public policy or a sound professional policy. The query is, How long can the profession be expected to afford to continue the practice?

The ethics of competitions would seem to be inseparable from the ethics obtaining in the general practice of architecture. The written circular of advice relative to the principles of professional practice, the canons of ethics and the conduct of competitions as prepared and circulated by the American Institute of Architects, form a very complete and helpful basis for the avoidance of the usual pitfalls and temptations due to an over-anxiety to get work at any cost.

The application of decent methods in practice rests entirely with the individual practising architect, who, armed with these traditional principles and possessing a broad and comprehensive vision, not to speak of a healthy and sincere desire to apply in addition to all this the golden rule to all of his dealings, must look unselfishly at the part he must play as a unit force in the great work of the present, in order that his architectural progeny may occupy that undisputed place in the affairs of the world that should rightly be given to those who (we at least believe) represent the greatest of all constructive professions.

The American architect of the future must of necessity become less of a creative artist, and more of a trained manager of building enterprise. The ever-increasing pressure for speedy and adequate execution will preclude more and more exhaustive study and tentative experimentation. It will become the duty of the architect to surround himself by specialists in design, in construction, in superintendence, in technical research and engineering; men representing every department of architectural practice, and possessing a knowledge in their individual capacity, perhaps, far beyond his own. The architect himself must remain, however, the master mind that organises and directs those who strive for the common cause of the work in-

NEW GENERAL OFFICES FOR THE STEEL COMPANY OF SCOTLAND, LIMITED, BLOCHARN STEEL WORKS, GLASGOW. J. GAFF GILLESPIE, F.R.I.B.A., ARCHITECT (SALMON AND SON AND GILLESPIE).

The above building was completed at the commencement of this year, at a cost of between £6,000 and £7,000. The site was part of an old quarry, and on that account the building is founded on a reinforced concrete raft.

volved and for the office. He will deserve to exercise a greater moral influence in public affairs than heretofore; for the scope of his organised efforts will be nationwide, and his authority will be that of a broadly trained executive of varied experience, which coupled with a high sense of duty should make him a generous and true friend of public spirit and the eternal fitness of things.

BUILDING INTERESTS IN SOUTH AFRICA.

*Specially written by our South Africa
Correspondent.*

Johannesburg,
March 11th, 1912.

State of Trade.

The building trade generally in South Africa continues in a prosperous state, and it is gratifying to report that during the past year the coastal towns have been receiving a fair share of the construction work in the country. Previously it has been the custom to look upon the Transvaal, with its large Government contracts, as the focus of all building energy, but, as I have pointed out, it is a pleasing feature of trade that now it is being more distributed and that all parts are having a due proportion. I am able to quote a few figures which I have collected for the past year, and which have not yet been printed in any journal. I find that in 1911 the value of plans passed by the municipality of Johannesburg was £1,810,754, which is an increase of £470,000 on the figures of the previous year. Taking the coastal towns, the value of plans passed during the year by the Durban municipality was £224,197, as compared with £189,200 in 1910. Cape Town municipality passed plans to the value of £96,000; Port Elizabeth £44,000; and East London £46,000. In the inland colonies there appears to be also growing activity, for I find that Kimberley passed plans to the value of £68,000 in 1910, compared with £20,000 for the preceding year. In Bloemfontein, in the Orange Free State, the figures have risen from £9,215 in 1910 to £36,184 in the past year. The total amount of plans passed for the four provinces was £3,195,279, as follows: Transvaal, £2,571,611; Natal, £259,077; Cape Colony, £326,257; Orange Free State, £38,334.

Imports.

As regards the imports of building articles into this country during the twelve months of 1911, statistics show that these were valued for £2,735,013, compared with £2,734,809 in the preceding year. It will thus be seen that there is a steady import trade between Great Britain and this country. The largest importations are in cement, electrical fittings, plate glass, galvanised and corrugated iron, paints, wood of all kinds, such as flooring and ceiling, house frames and parts thereof, and zinc and zincware, which individually are represented by six figures.

The Federation Congress.

It is now about a year ago since the South African National Federation of Master Builders met at Bloemfontein, and the next Congress will be held at Port Elizabeth on April 15th. I understand that a large number of most important subjects affecting the building trade are to be deliberated upon. The subject of universal conditions of contract is one that will loom largely in the proceedings, as well as that of the con-

stant menace of coloured skilled labour, as it affects white labour in this country. Both of these subjects are of the utmost interest to all builders, and will receive their due meed of attention. Amongst other matters to be brought forward will be an Architects' Registration Bill. The points with regard to this have been raised by the quantity surveyors, and are supported by the executive of the National Federation. These are—that quantities, if they are to be referred to in the Architects' Registration Act, should be guaranteed; that they should be taken out by a duly qualified surveyor; and that it should be an offence under the Act if this is not carried out. The Federation, it is understood, will have its attention directed to the proposed Bill, and endeavour to assist in securing a clause in it which will give effect to the above.

Johannesburg New Town Hall.

The new town hall of Johannesburg will take about three years to build. The contractor is Mr. M. C. A. Meischke, whose tender was accepted for £293,938. The foundations have all been laid, and building was started on the 1st of this month. The site is on the Market Square, opposite the General Post Office.

Construction Work in Johannesburg.

One is much impressed with the amount of construction work just started in the central parts of the town near to Park Station. The new Young Men's Christian Association building at the corner of Joubert and Bree Streets is being erected, and opposite that the ground is being cleared away for a magnificent building to be erected for the Union Club. Not far from this a very handsome building of offices and residential chambers is being erected for the African City Properties Trust, Ltd., while in the same neighbourhood the New Lyceum Theatre is in course of construction. Messrs. Chudleigh Bros.' building, which will cost, when completed, some £80,000, is also in course of erection in Eloff Street, and is a grand structure from every point of view. Such huge buildings as these, and also the one recently completed for Messrs. Anstey and Co. in Kerk Street, go to prove the great amount of confidence that merchants have in the stability and future of Johannesburg. All the buildings I have mentioned are within a short distance of each other, and the tendency seems to be towards this becoming the real mercantile centre of the city.

Building in Pretoria.

The new Union Government Building in Pretoria is making rapid progress, and one is already beginning to notice how much architectural effect and character it will exhibit when the plans are fully carried out. Situated on Meintjes Kop, the building will rest mainly on a rock, the strata running in the opposite direction to the slope of the hill. The building is designed to meet the needs of the southern climate, and it is interesting to note that the buildings are constructed as far as possible by local material and local labour. The architect is Mr. Herbert Baker, F.R.I.B.A., and the work is being carried out under the supervision of the Public Works Department. The contractor for the eastern and western blocks is Mr. M. C. A. Meischke, the contract amount being £622,500. For the amphitheatre block, which will cost £256,224, Messrs. Prentice and Mackie are the contractors. The total outlay for the blocks is £878,724.

CORRESPONDENCE.

Cheap Cottages.

To the Editor of THE ARCHITECTS' AND BUILDERS' JOURNAL.

SIR,—“I licentiate R.I.B.A.” in your issue of March 27th, evidently has a limited knowledge of the practical ability of the type of artisan who is usually called upon to erect a simple country cottage, if your correspondent thinks that a farm labourer can be employed as his substitute. Roadmaking, farming, thatching, and well-sinking are the daily work of agriculture; but tiling done by farm labourers means leaky roofs, to say nothing of deplorable appearance.

The writer's experience of country contracts has been that local men are only fit for rough excavating or carting. Their intelligence is limited or latent; and builders find it more economical to employ experienced builders' labourers and pay them higher wages than the local rates. It follows, therefore, that if the country labourer is unfit as a general builder's labourer, he can hardly be expected to do the work of a skilled artisan.

Respecting monastic building, it is no doubt true that in the Middle Ages the brothers did some skilled work; but in the modern monastery a Catholic layman is employed to superintend the work and to engage skilled operatives for carrying it out.

CLERK OF WORKS.

DETAILS, OLD & NEW, XXXIX.

Collin's Hospital, Nottingham.

Collin's Hospital, Nottingham is a most interesting example of early eighteenth-century work, though the name of the architect is not known. All the essential particulars of the materials and construction are given on the drawings reproduced on the following pages. To the inscription over the north entrance, given on the Centre Plate, it may be added that the hospital was founded originally for the reception of 24 poor men and women, each of whom was provided with two comfortable apartments, and 2s. per week, with a ton and a half of coals per annum. The general dimensions of this entrance correspond with those of the south entrance, of which complete details are given on pages 381 and 384. The doorway in its relation to the whole front is shown by the north elevation on page 382.

“The Year's Art.”

As a faithful record of the year's happenings in the art world, this annual is always interesting, and its value in this respect is greatly enhanced by the inclusion of many full-page plates illustrating subjects which in various ways assumed topical interest during the period covered. The editor's review of “The Past Year” is exceedingly well done, although a disproportionate amount of space is given up to a rather dithyrambic lament on the theft of the “Monna Lisa” from the Louvre. “As the years go by the horror of the loss will increase. . . . It is a world-tragedy,” and so forth. All the more noteworthy institutions in any way connected with art are succinctly described, architecture being of course included, and there are lists of fine-art dealers, as well as a directory of artists and art workers. The publishers are Messrs. Hutchinson and Co., 34, Paternoster Row, E.C., and the price 5s. net.

PHENIX FIRE INSURANCE
OFFICES, LEEDS.

This building occupies an excellent site in South Parade, Leeds, formerly in the possession of the Young Men's Christian Association, who have recently erected new premises in Albion Place. The Phoenix offices are faced with dressed stone from the Cullingworth quarries, and are roofed with Tilberthwaite slates. The staircase and floors generally are of fireproof construction. The rooms occupied by the Phoenix Company comprise a large general office 28 ft. by 23 ft. and separate offices for the manager and typewriters. The remainder of the building is devoted to suites of offices let off to various tenants. Messrs. Henry Atkinson and Sons were the contractors for the masons' and bricklayers' and carpenters' and joiners' work; Mr. William H. Thorp, F.R.I.B.A., of Phoenix Chambers, Leeds, was the architect, and Mr. William H. Tarran, of Fulford, York, the clerk of works.

FIRE PREVENTION NOTES.

The effect of climatic conditions on fires is rather strikingly shown in a tabulated record

*A Month's
Five Losses.*

which has been published of the principal fires that occurred in the United Kingdom during last March. The fires were comparatively few because March was a wet month, and because there were no extremes of cold to cause the overheating of buildings. The list shows that the total estimated loss for the month amounted to £123,200, which compares somewhat strikingly with £250,900 in March, 1911, and with £244,600 in February of the present year. These figures, however, all exclude fires in which damage to a less amount than £1,000 was claimed for in the insurance offices; and it must not be forgotten that such claims, being very numerous, amount in the aggregate to a very substantial sum, revealing still more strongly the need for precautions against fire in buildings other than the large factories, and so forth, comprised in the list, in which there is only one "private house," unless the "mansion" may be taken to be the same thing under another name. At the former, damage was done to the extent of £2,000; at the latter, to the extent of £2,500. The other buildings may be roughly described as factories of various kinds, although the three timber yards are hardly within that category. In two of these yards the losses are returned at £8,000 each, and this is the highest figure recorded, with the exception of the sweet-factory fire at Newport on March 30th, in which the loss is estimated at £15,000.

Sir William Ramsay's suggestion (after luncheon) at the opening of the Smoke Abate-

*A White
World.*

ment Exhibition, that coal-mines might be worked more economically by sending up the product in the form of gas, has set people wondering why so simple and so obvious a remedy for strikes had not been adopted years ago. Just as deposits of salt are worked, not by mining the salt, but by pumping-in water which is recovered as brine, so, thinks Sir William, "it would be ideal," instead of mining coal, to have retorts in the bowels of the earth for the production of gas. The gas might be used in gas-engines at the pit-mouth for the pro-

duction of electricity, which might be distributed by high-tension currents to any desired point. By this means it might be possible to produce electricity, to be used for heating, at a price of perhaps one-hundredth of a penny per unit. Coming from a man of science of Sir William Ramsay's eminence, the suggestion is not to be lightly disregarded; yet, to the lay mind, the making of gas in a coal-mine seems to be fraught with the most appalling possibilities of catastrophe. So also does the extreme cheapening of the cost of electric current, whether by this or by any other means. The general use of high-tension current—which seems to be pretty confidently predicted by many others besides Sir William—will, or ought to be, accompanied or preceded by a drastic revision of many of the details of building construction, with very particular reference to the problems of fire-prevention. In suggesting that the realisation of his suggestion would probably abolish miners' strikes, Sir William—no doubt from motives of delicacy—refrained from mentioning that inferentially it would also abolish smoke-abatement exhibitions; which might perhaps be superseded by fire-prevention exhibitions.

PHENIX FIRE INSURANCE OFFICES, SOUTH PARADE, LEEDS.
WILLIAM H. THORP, F.R.I.B.A., ARCHITECT.

*Cost of London
Fire Stations.* The economically minded ratepayer will be reassured to hear that the capital esti-

mates for a number of proposals relating to the L.C.C. fire brigade exceed the cost of the works or the actual price of the acquisition, as shown in the following list:—Brixton fire station—acquisition of site and erection of building: reduction by £8 14s. 9d. to £11,871 5s. 3d. Cannon Street fire station—acquisition of site and erection of building: reduction by £2,033 3s. 1d. to £60,416 16s. 11d. Waterloo Road fire station—acquisition of property: reduction by £2,980 18s. 7d. to £5,519 1s. 5d. Tooting fire station—erection of building: reduction by £1,141 4s. 7d. to £12,272 13s. 6d. Vauxhall fire station—conversion into a full station: reduction by £650 to £1,850. The aggregate of the approved estimates was £98,743 18s. 4d., and that of the reduced estimates is £91,929 17s. 4d., so that the total extent of the reductions is £6,814 1s. The working drawings and the draft specification for the new fire station to be erected on the site of the existing Hackney station and of No. 2, Bodney Road, Hackney, have been prepared, and quantities are to be taken.

PHOENIX FIRE INSURANCE OFFICES, LEEDS. WILLIAM H. THORP, F.R.I.B.A.,
ARCHITECT.

out and lithographed at an estimated cost of £200, which will be charged against the capital estimate of £14,500.

Five Brigade Competitions.

Our observations, in a recent issue, on the benefits accruing from the encouragement of fire-brigade competitions have had a gratifying sequel. In the report of the Fire Brigade Committee of the London County Council printed in last week's agenda, it is announced that, in order to encourage smartness and to promote increased efficiency among the members of the fire brigade who man the horsed escapes and motor escapes, it is proposed that an annual competition shall be held between the staffs of the various stations throughout the brigade. It is suggested that preliminary tests shall be held in each of the six brigade districts, and that the final test shall be held at the chief station between the best teams in each district. It is further proposed that, in order to increase the interest taken by members of the brigade in the competition, money prizes should be awarded, and that these should be as follows: To each member of the teams securing the first, second, and third places in each of the six brigade districts, 15s., 10s., and 5s. respectively; and to each member of the winning team in the final competition, £1. Each team will consist of four men. In these proposals there is nothing to indicate that the public will be afforded an opportunity of witnessing the competitions. For two reasons, this seems to be rather a pity—the presence of the public would afford an added stimulus to the competitors; and the public would benefit by increased interest in the brigade and in the general subject of fire-fighting. The more the public can be induced to turn their attention to such matters in their broad aspect, the greater will be the proportion who may be expected to give due regard to details of fire-prevention as well as to those of fire-suppression.

HASLAM PARK, PRESTON.

The Preston Town Council have under consideration Mr. T. H. Mawson's scheme for the laying out of Haslam Park, at Preston. The total estimate for the landscape construction, and planting amounts to £10,647. The total park area is 273.333 sq. yds., or 56½ acres.

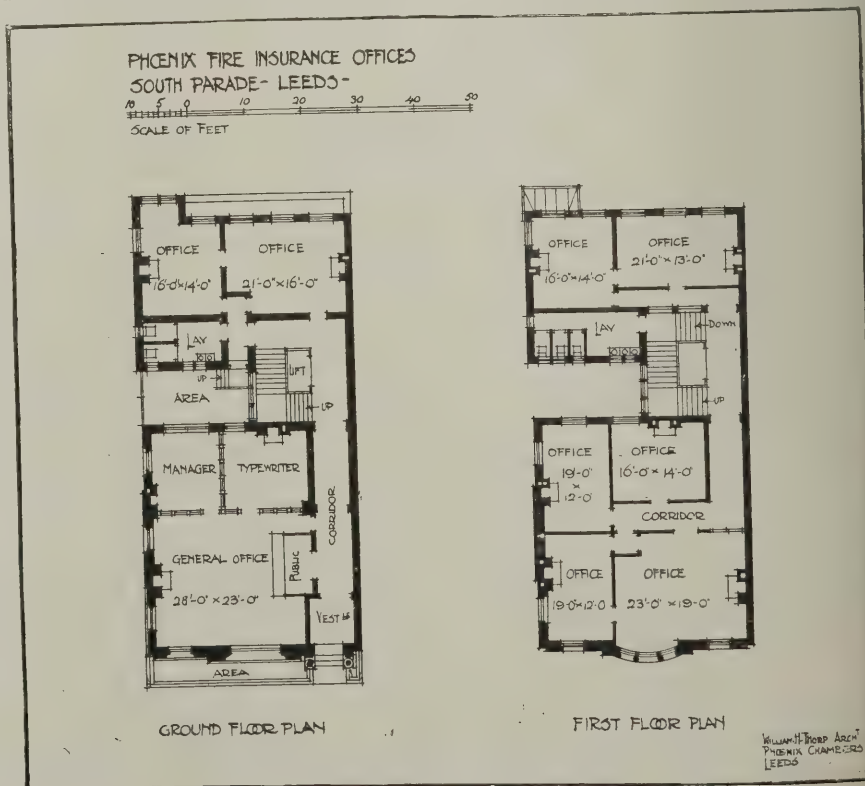

The detailed figures prepared by Mr. Mawson show that the idea of a recreational park has not been lost sight of, but there is, nevertheless, an attempt to give quiet retreats wherein to foster interests which shall appeal to the aged and lovers of nature.

More than 22,000 sq. yds. are to be utilised for a lake. "An exceptional opportunity," Mr. Mawson reports, "is provided by the stream that runs through the park, which, even during the phenomenally dry summer we have experienced, has given a constant supply of fairly clean water, sufficient to form a boating pond of considerable extent. The levels of the ground, the fall of the stream from end to end, and also the nature of the soil and subsoil, make such a lake a sound proposal, which, by the hire of boats, would probably earn interest on the outlay, or at least provide a considerable sum annually towards maintenance."

On the playing field side of the main avenue—which it is proposed to plant with a double line of limes, as in Moor Park—it is recommended that there should be erected—about equidistant between the two entrances—a shelter pavilion, simply but none the less architecturally treated, and provided with good dressing rooms and conveniences.

The avenue and playing fields are parts of the original scheme which have been retained, but much of the remainder is either opposed in principle to, or additional to, the old plan. "The most important deviation is the provision of a new roadway wide enough to be used on occasion by vehicles. Entering the park at the south-east corner, it extends by flat curves to a point opposite Bostock's Farm, crossing the lake in its course by two bridges, which it is suggested might be of a simple trestle design. The position of the south-east entrance and the drive immediately within the park gives an excellent axial line, on each side of which are arranged the children's playground, bowling greens, bandstand, and tennis lawns. There is also, on the east side of the first bend, a space large enough for an excellent hockey ground. This arrangement allows of economical working and control.

The designer has issued, with his report, a design for the lay-out of the park, which shows very graphically the woodland effects that are contemplated

IN PARLIAMENT.

ECONOMY OF GAS POWER.

(By our Press-Gallery Representative.)

Lighting of the House of Commons.

Mr. Wedgwood Benn, on behalf of the First Commissioner of Works, has stated that it is proposed, if found desirable after experimenting, to substitute electric lighting for gas in the debating chamber of the House of Commons. This, he said, would probably be more efficient, and would certainly reduce the cost of lighting. It was intended to carry out the work in sections in order to give members an opportunity of observing the effect of the change.

Mr. Bowerman suggested that the lighting of the Terrace should be improved. Mr. Benn said there was no provision on the Estimates for that, but the First Commissioner would be glad to consider the suggestion when preparing the estimates for next year.

Mr. Ormsby Gore wished an opportunity for the House to discuss the lighting arrangements, and suggested that, in the opinion of leading oculists, gas light was less harmful than electric light. He also asked whether gas assisted in the proper ventilation of the House. Mr. Benn replied that an opportunity would arise for discussion on the vote for the Houses of Parliament. The First Commissioner was not aware that leading oculists had expressed any such opinion in regard to lights placed as the lights in the House of Commons would be. Gas did not assist in the ventilation of the House, and under the proposed arrangements the House would be better ventilated than heretofore. Mr. Mildmay desired to know if the alterations would include some alteration in the methods by which cold air was pumped up from under the seats. Mr. Benn said it was not contemplated to alter the form of ventilation.

The Building Line in Edinburgh.

Mr. Hogge asked the Secretary of Scotland whether his attention had been drawn to the fact that the Government proposed to erect a new building in Inverleith Row, Edinburgh, on a frontage line which did not comply with a local by-law prohibiting the erection of any new building within a distance of 30 ft. from the centre of the street, and if he would give an undertaking that the proposed building would not be proceeded with. Mr. Benn, who replied, said the question was at present *sub judice*, and in the circumstances he was unable to give the undertaking desired. He further stated that an appeal was being taken against the decision obtained in the courts against the Government.

Government Offices in Dublin.

Questions having arisen in the House of Commons as to the provision of new offices in Dublin for the various branches of administration, and the necessity for proceeding with the new buildings in Upper Merion Street, Mr. Masterman, Secretary to the Treasury, explained that the only cost estimated in connection with the unfinished part of that scheme was that of the architects' plans—something like £2,000. There was considerable doubt whether the buildings as originally planned would be proceeded with in view of the changes which might take place in future. Several Irish members suggested that the work should be put in hand at once in view of the fact that money was being spent in Dublin for the relief of distress.

In a lecture before the Society of Engineers and Metallurgists on the economy of gas power over steam, Mr. Alan Chorlton, of Messrs. Mather and Platt, Ltd., Manchester, claimed that so completely satisfactory and reliable had the gas engine now become that every day saw its application extended to duties so difficult and onerous that only a few years ago they would have been thought impossible of achievement. The invention of the producer, its progress and improvement to date, had, of course, extended the field of the gas engine enormously. Mechanical and thermal efficiencies had steadily increased in recent years, and the reliability of the gas engine had been brought up to the standard of the one-time omnipotent steam engine. A waste gas that was at present receiving more attention even than that from blast-furnaces was that which was obtained from the by-product coke ovens. These ovens were now at work or being laid down in considerable numbers in this country, but even in this matter we were far behind the expansion that was taking place in Germany. Such was this expansion that, with the typical German ability of working together, the coke-oven owners were now selling large quantities of waste gas from these ovens for illuminating purposes in the adjacent towns. In this country the only place where such illumination was carried out was Little Hulton.

Mr. Chorlton predicted that when further progress of this nature took place in districts adjacent to coalfields, it would last of all affect Sheffield, which already compared favourably in the price of gas supplied retail (11d.) with that supplied in gross by the German concerns (8½d.).

TRADE AND CRAFT.

Carron Interior Grates.

The Carron Company, of Carron, Stirlingshire, and Phoenix Foundry, Sheffield, have issued a handsomely illustrated list of their new series of segmental interiors, the designs for which they are confident will specially appeal to the taste of architects. Whilst simplicity is the dominant note in these designs, the fourteen varieties shown admit of wide diversity in taste and circumstance; material, pattern, and finish giving a considerable range of choice. Many of these interiors are perfectly plain; but in those in which decoration has been introduced it is always chaste and dignified.

A New Joinery Catalogue.

Messrs. C. Jennings and Co., Earl's Mead Joinery Works, Pennywell Road, Bristol, have issued a 264-page catalogue containing prices for nearly every article of woodwork in use; the firm claiming to produce doors, windows, joinery, and mouldings of every description, of good quality, at competitive prices. The woodwork illustrated ranges from simple cottage doors to elaborate work in best Austrian oak, teak, mahogany, and other high-class woods; and a special feature of the list is a set of designs—some elaborate and others inexpensive—of fretwork for arches, vestibules, etc., showing clearly the excellent effects which can be obtained at small cost with this class of work. The book is obtainable in exchange for professional or trade card and 5d. in stamps.

A New Metal Filament Lamp.

In a booklet that has just been issued by the British Thomson-Houston Co., Ltd., Mazda House, 77, Upper Thames Street, E.C., the announcement is made that those users of the electric light who have continued to employ the old-fashioned carbon lamp because they consider metal filament lamps too expensive need no longer take this factor into account. The new B.T.H. Gem lamp costs only 2d. to 2½d. more than the ordinary carbon lamp, is British-made, and can be obtained in two efficiencies—2½ watts per candle, and 2.8 watts per candle. Gem lamps, for which it is claimed that, while giving a light of superior brilliancy, they effect a 25 per cent. economy in the consumption of current, saving the consumer 6s. 4d. in every 1,000 hours of service where the price per unit is 4d., or 7s. 11d. where it is 5d., are made for voltages of from 100 to 130 volts, but can be ordered and used in series on 200 to 250-volt circuits. The Gem lamp, with its improved "metalised" or "graphitised" carbon filament, represents, it is claimed, the most important development in carbon lamp manufacture that has taken place in recent years, the gain in efficiency being obtained without any sacrifice of service results. The 2.8 watt lamp has an average life of 1,500 hours, the 2.5-watt lasting 800 hours—in each case with well-maintained efficiency.

MIDDLESEX HOSPITAL EXTENSION.

Her Majesty the Queen, on March 27th, opened the Barnato-Joel Cancer section of the Middlesex Hospital, of which the foundation-stone was laid in July, 1910. Mr. E. T. Hall, the architect; Mr. James S. Holliday, the builder; and Mr. A. M. Coombs, the consulting electrical engineer, were among those who had the honour of being presented to her Majesty by Prince Alexander of Teck. The key with which the opening ceremony was performed was designed by Mr. E. T. Hall and executed by the Goldsmiths and Silversmiths' Company.

The extensions are built to the west of the hospital, to which they are connected by corridors, subways, and a garden approach. They comprise forty-three beds for patients, a home for fifty-nine nurses, bedrooms for twenty servants, an out-patients' department, an entirely new research department, an operating theatre, and an apartment for electrical treatment.

The new buildings are English Renaissance in style, that facing the street being externally of red brick and Portland stone, the others being of white brick and similar stone. All the floors and flat roofs and partitions are of fire-resisting construction. On the first floor of the Nassau Street building, which is five storeys high, there is a ward of 20 beds. On the wall of this landing, by the entrance to the ward, is a specially designed bronze tablet denoting that this is the "Queen Mary" Ward. Over the fireplace at the south end is a portrait of her Majesty presented by the architect. The second floor contains similar accommodation, the ward being dedicated to the late Prince Francis of Teck, of whom there is a portrait. In this ward, with the exception of two wards and day rooms, the old Cancer Charity has been remodelled throughout, and another storey has been added to both wings. The eastern block is six storeys in height.

NEWS ITEMS.

The London Labour Movement.

As already reported, the several sections of workers in the London building trade are asking for a common rise of 1½d. per hour, and this demand is being considered by a special committee appointed by the council of the London Master Builders' Association. Although it is hardly likely that the full demand will be conceded, a Press representative who made inquiries among officials on both sides last week learned that the possibility of a strike is regarded as being rather remote. There has been no alteration in the rate of wages paid in the building trade since 1900, when the carpenters and masons obtained an advance of ½d. per hour.

Ancient Monuments Protection Bill.

This Bill, which was introduced by Lord Southwark in the House of Lords on March 14th, acts upon the report of the Royal Commission on Ancient Monuments that valuable monuments are being lost and urgently need preservation. By the Ancient Monuments Protection Acts, 1882 to 1900, an owner of a monument may in certain conditions obtain the guardianship of the Commission of Works for a monument. The present Bill gives power to the Commission of Works, with the advice of an advisory board, to secure that historic monuments shall be preserved from destruction and decay. The great majority of owners already preserve such buildings. These will be unaffected by the Bill.

Preserving Oxford's Old Houses.

A sub-committee of the Oxford Architectural and Historical Society has been formed with the object of preserving the old houses at Oxford. They propose "first to schedule all existing houses and other antiquities that possess special architectural or historical value; (2) in the event of any buildings, etc., on this list being threatened with demolition or restoration, to do all that is possible to preserve them; and (3) to make, catalogue, or collect pictorial and descriptive records of houses, etc., in the schedule, and also of those of similar character that have disappeared."

The Shakespeare's England Exhibition.

The buildings for the exhibition to be called "Shakespeare's England" are now being erected at Earl's Court. These are formed largely of a fireproof composition which can be made to look exactly like stone or brick or wood as may be desired. Innumerable architectural details are being moulded on the spot and built into place on plans drawn largely from Messrs. Garner and Stratton's and Mr. Gotch's volumes, together with the Architectural Association's sketch-books. The exhibition is to open on May 9th.

Shakespeare National Theatre.

In May, 1911, the London County Council granted to the Shakespeare Memorial Committee an option terminable at the expiration of one year from April 1st, 1911, to purchase, subject to any necessary consents of the Local Government Board, and of lessors of any of the property affected, and on terms to be hereafter determined by the Council, the Council's interests in the county hall site upon the vacation of the premises. The committee have asked that this option may be extended for a further period of one year, and the General

Purposes Committee have recommended that the Council shall accede to this request.

The Australian Commonwealth Buildings.

Although only a few weeks have elapsed since the "island site" in the Strand was acquired by the Australian Commonwealth Government, the work of excavating for the foundations is already well advanced. It is reported—but it is to be hoped that the rumour is not true—that the Commonwealth Government have determined to establish a record for London in the rapidity of erecting this building. The balance of the purchase money—£370,000—is about to be paid, and the Government consider that, as they will be losing interest on that sum at the rate of between three and four per cent., until the new building is ready for occupation, and as they are paying rent for the present offices in Victoria Street, the greater the expedition the greater the economy. It is expected that the foundations will be finished, and the tenders for the superstructure let, by August next, and that the building will be ready for occupation with in two years.

SOME USEFUL YEAR BOOKS.

The City of London Year-Book.

No higher praise can be given to this Year-Book than to say that it is quite worthy of the city whose name it bears and whose interests it serves in every way conceivable or possible in such a relation. Commerce, education, religion, and very especially civics, are dealt with concisely and informatively; and besides the past year's record of transactions of the Corporation and of the London County Council, there is a general history of each of the City Companies. The directory portion is well arranged and classified; and altogether the book is an invaluable guide to City interests, actualities, and activities. It is published, price 5s. net., by Messrs. W. H. and L. Collingridge, 148 and 149, Aldersgate Street, E.C.

Northern Counties Federation Year-Book.

That a carefully compiled special year-book is of value and importance in bringing together a collection of facts and data relative to particular interests is quite beyond question, and the Northern Counties Federation of Building Trades Employers are therefore wise in continuing their annual, and in endeavouring to enhance with each issue its utility to those for whom it is especially prepared. It is at once a record and, in a limited sense, a directory for the building industry of the North of England, as it contains as well as the twelfth annual report of the Northern Counties Federation, and a digest of recent legal decisions, lists of trade members and sub-traders, of local authority officials, rates of wages, conditions of contract, and other useful information. The book, of which this is the third annual issue, is edited by Mr. W. H. Hope, of 14, Norfolk Street, Sunderland.

Year-Book and Directory of the Midland Centre.

Similar to the Northern Counties Year-Book in contents and arrangement is the "Year-Book and Directory of the Midland Centre." To the membership

lists, local directories of traders, rates of wages, contract forms, etc., are appended many pages of useful memoranda and tables. The secretary of the Federation, from whom presumably the book is obtainable, is Mr. Fred W. Amphlet, 58, New Street, Birmingham.

OBITER DICTA.

Art Judicially Defined.

MR. JUSTICE DARLING (to Mr. Jellicoe).—If you know anything of art, as I dare say you do, you would know that anything that is pretty is not artistic; if it is ugly it is artistic, and if it is absolutely nauseous it is very artistic indeed. (Laughter.)—*High Court of Justice, March 21st, 1912.*

Expectant Genius.

There is no reason why our cities, towns, and villages, especially London, should not have things dignified and beautiful and well placed; for many of our architects, sculptors, painters, and designers, who are the joy and envy of other nations, are anxiously waiting to give the best of their genius, if called upon to do so.—*Sir George Frampton, R.A., in the "Journal of the Imperial Arts League."*

Too Many Critics.

I am a little sceptical about the new "London Society." It is to make every Londoner a critic, but it cannot insure that any two critics will agree. As things are now the learned are content to dispute about Renaissance architecture, but with all London interested in the matter there would be a movement to pull down St. Paul's Cathedral, a counter-movement to defend it, and consequent riots on Ludgate Hill.—*"The World."*

Egg and Dart (Parthian).

A candid American architect, when pressed to tell how our buildings struck him, said: "Why, I guess they look like scrambled eggs."—*Mr. C. C. Brewer at the Architectural Association.* [In the ensuing discussion, Mr. J. M. Whitelaw said that, in view of the avidity with which American architects "conveyed" or copied details, it would be fair to retort that American architecture reminds us of poached eggs.]

Architectural Study.

One deplores the falling-off of the acquisition of archaeological knowledge and interest amongst younger architects. The great impulse given to the study of our ancient buildings, more especially churches, during the wave of church restoration in the latter half of the last century, acted in the most impelling manner in producing amongst architects many scholarly exponents of mediæval art throughout the country. The decline of this wave of restoration, and the revive appreciation of Classic and Renaissance traditions, had decreased the flow of study amongst architects as well as among the clergy who had done so much in the past to instil a love for the study of the beautiful buildings under their care. It may be hoped, however, that the newer interest may widen the whole sphere of art, and produce even more enthusiastic exponents of the historical study of architecture. To advance the training of our young brethren, one would suggest, in addition to classes, lectures and visits to buildings under trained guides.—*From president address by Mr. James Jerman, F.R.I.B., to Devon and Exeter Architectural Society.*

What Might be Done with the Crystal Palace.

Ordinary days, when there is no special attraction, such as a Good Friday concert, or a cat show, the Crystal Palace and grounds are now rather a melancholy waste, haunted only by a few sparsely scattered visitors. Even the large population of the neighbourhood, who used to regard it as a daily pleasure haunt, seem to have got tired of it. The reason seems to be, or at all events the excuse might be, that there is no central principle about it; the place has become a medley of things, nearly all of them advertisements of some kind, and the glory of the gardens has departed. The fame of the old Saturday concerts used to draw crowds there once a week, which kept up the prestige of the place; but now there are as good concerts to be heard in town, without a railway journey to them; and the Crystal Palace has dropped more and more out of notice.

But the Palace and grounds represent a great opportunity, which it would be a thousand pities to lose. The most definite proposal before the public now is that it should be made into a great "Folk Museum," illustrating the history of the nation in its architecture, art, industries, and amusements. In regard to the architecture of daily life in the past, it is proposed by the Committee concerned in recommending this idea, that this would be an opportunity for purchasing old and picturesque houses that would otherwise be unavoidably destroyed, and re-erecting them in the grounds. For the remainder of the scheme we may quote from the article which appeared in the "Museums Journal" in February, and which has been since reprinted and circulated as a statement of the case:—

"The Crystal Palace itself would serve for the display of a developmental series of furniture, pottery, glass, ironwork, textiles, etc., and for collections illustrating the customs, distinctive beliefs, amusements, personal ornaments, inventions, etc., of the English peoples. The ample dimensions of the building would enable some of the collections to be arranged as interiors; thus there might be a 'Chippendale' room, a 'Hepplewhite' room, a 'William Morris' room; also a room devoted to the apparatus and methods of producing fire in past times, a room for children's toys and games, a Folk-lore room, and so on. It would be especially appropriate if a part of the Crystal Palace could be assigned to collections—ceremonial robes, portraits, personal relics, and the like—relating to the past and present members of our Royal house. If precedent were needed, one can be found in the Royal collections preserved in the Rosenborg Castle at Copenhagen."

There is a good deal to be said for this latter part of the programme, and a very interesting permanent exhibition might be made in that way; but we doubt whether that will revive the Palace as a public resort. A good many people will go to see it once, but they will not keep going for any other inducement than the study of a Folk-lore museum. There is something more to be done with the place than that; what it is we will try to indicate.

To begin with, it seems to be overlooked that a considerable space is now occupied within the Palace by illustrations of phases of architecture of the past—not national,

but of a wider significance. There are an Egyptian Court; a Greek Court; a Saracenic Court (representing part of the Alhambra architecture); a Florentine or Renaissance Court, containing very fine casts of Michelangelo's four great recumbent figures; and a Gothic Court. Some of these are very well done; the Alhambra Court, carried out by Owen Jones, especially so; and in the Egyptian and Greek Courts, though the small scale to which the Egyptian architecture is reduced may seem rather absurd, the details are quite correct and were carried out under competent supervision. The Gothic Court is the poorest, and is, in fact, worth very little as an illustration of mediæval work, which was not properly understood at the time. But the greater part of this work is good and useful illustration of great styles of architecture; to destroy it would be a mere piece of vandalism; and it does not fall into the English Folk-lore scheme.

Our advice is that this series of architectural courts should not only be preserved but extended. The existing ones now occupy the outer portions of the nave in the half of the Palace north of the centre transept. Similar courts, under competent architectural authority, should be formed in the corresponding portion of the southern half of the Palace, illustrating other main phases of the architectural styles of the world—Byzantine, Romanesque, phases of Gothic in different countries, etc.; there are plenty of styles worth illustrating, and they should be accompanied by representations of the decorative and applied art which belonged to each period. Thus a feature which is at present incomplete, and has been fairly well begun, would be completed on the same plan. These side-courts would then represent the world's architecture, and the wide central space of the nave could be devoted to what is especially illustrative of English history, art, and industries, for which it ought to afford ample space. This would fortunately involve the destruction of that Early Victorian absurdity, the "Crystal Fountain," which stands under the smaller transept—the central transept of the 1851 Exhibition building; unless indeed that should be thought worth preserving as a piece of Folk-lore! It certainly is a curious landmark of how taste has progressed in the last half-century in this country, to reflect that this preposterous piece of glass gimcrack was solemnly erected in 1851 as the central ornament of an exhibition of arts and industries, and was not only tolerated but admired.

And out in the grounds, no doubt, might go the proposed rebuilt specimens of ancient domestic architecture, guarding, as it is said, "against the incongruous effect that would result from placing in close proximity buildings out of keeping with one another." Also let us note that "much could be done by screening neighbouring buildings with trees, and by taking advantage of inequalities of surface. Some of the houses might have associated with them old-fashioned gardens with appropriate flowers and herbs." That might be made into a tolerably decorative scheme, if only one could get a sufficient number of old houses that are worth having, to rebuild. That is a point on which we should feel rather doubtful.

The scheme as a whole might answer, but it would not make the Crystal Palace what it has been and might be again: a pleasure resort. It would be a museum, to which

people would go to study the subject illustrated, when they wanted to study it. But in fact museums are rather things for towns; places where people may go to find matter of interest when the weather is uninviting for outdoor enjoyment. Is there nothing better to be done with the Crystal Palace than that?

In England we are so beset with the idea of providing instruction for the people that benevolent persons never seem to think of providing them with pure enjoyment. Yet there could hardly be a place better fitted than the Crystal Palace to make a palace of pleasure out of; a place simply desirable for its beauty and for the beautiful things in it. Look at that view from the terrace, how beautiful it is; look at that sloping ground, how admirably suited for making a beautiful garden out of; "taking advantage"—in the words already quoted—"of the inequalities of the ground." There is the possibility of making there one of the most beautiful gardens in the world, with avenues, fountains, sculpture, parterres of flowers, and so on. With better arranged and speedier access by rail and tram (which is certainly needed), such a garden would attract people, without any Folk-lore houses; which might, however, be added in some part of the ground set apart for it, so as not to interfere with its general proposed character as a pleasure-ground. Why were there crowds of people in Hampton Court Gardens on the Saturday afternoon between Good Friday and Easter Sunday? Because it is a beautiful place. The galleries of the Palace were closed that day—we know not why; but people did not want them particularly; they came in crowds to be in a beautiful garden. Make the Crystal Palace grounds a beautiful garden, and they will come there in crowds too. It would be a large operation, but it might pay in the long run; and even if it did not pay in money return, it would be worth doing with public funds. We have few enough beautiful places; here is a chance of making another.

And one of the principal things to be seen to in such a case, both for the Palace and its grounds, would be to decree against the whole tribe of advertising erections. At present every erection in the grounds is merely a blatant advertisement of something or other; and the interior, except for the architectural courts, is a mere bazaar. It is all very well to provide that any erection of the kind must be decorative; the public soon see through that, and do not want kiosks which are advertisements. For the interior of the Palace what we would wish to see, after the completion of the series of architectural courts (which would be really worth doing if done well), would be a winter garden, with concerts, and with a whole range of sculpture. It was remarked by a writer on art a good many years ago that the series of sculpture casts then in the Palace made one of the best representative collections of sculpture within reach of London. The collection seems to have been somewhat depleted since then, and there are casts there that are not worth much; but a fine collection might be made both of English and of French sculpture; casts when originals cannot be had. And as there is such a want of encouragement to sculptors in England, let the Government in that case do what the French Government in a similar situation would undoubtedly do—purchase a selection of sculpture every year from the Royal Academy exhibitions, to add to the Crystal Palace collection.

The Folk-lore Museum idea would no doubt be far better than letting the Crystal Palace be demolished. But we do not regard it as the best idea. Museums are places for towns. We want to see the Crystal Palace and its grounds made into a place of beauty; purely for the sake of beauty and not for instruction. And if private enterprise cannot undertake this, the Chancellor of the Exchequer has a large surplus this year, and does not clearly know what to do with it. A small proportion of it, wisely laid out, would suffice to make the Crystal Palace a garden of delight; and the expenditure would be well worth the occasion.

Regent Street Architecture.

WE observe from letters in the papers that an agitation is again being got up to endeavour to condemn Mr. Norman Shaw's grand piece of street architecture in Regent's Quadrant, and set up the theory that London street architecture is to be controlled by the shopkeepers and their imaginary notions about their own interests. We say imaginary because the notion that shops cannot be prosperous or remunerative unless the whole front is made of plate-glass, with concealed supports behind or above it, is an entire delusion. It is simply the notion of ignorant people that because a fashion has lasted for a certain time it must be right, and that nothing else can be. Possibly there may be something in it in a case where one shop had a window space limited by architectural piers, and the next door one had unlimited plate-glass; but we are not sure even of that. The times are coming, and have to some extent come, when a good architectural treatment of a shop front will be an asset in a commercial sense, giving the shop a superior aspect. This, of course, the average shopkeeper cannot understand; he cares nothing about street architecture, and thinks that the show of his own goods through a gaping opening covered by plate-glass must be more attractive to his customers than any architectural superiority in his "front." Those who think so may live to find themselves mistaken. There seem to be a few who know better already. Near the top of the Haymarket, for instance, is a well-known cigar-shop which has the old style of front with windows on a curved plan and with small panes, which was once the most usual treatment of the London shop-front. According to the ideas of the Regent Street vandals, as we may call them, this front, in the interests of business, ought to have been long since demolished, and a flat piece of plate-glass substituted. Obviously the proprietors of this shop have known better, and have had sense enough to see that the old front gives a superior appearance to their premises and is an attraction in itself.

The agitators against Regent Street architecture point to a firm of valuers who state that on the preparation of plans for the Piccadilly Hotel they were employed by the syndicate to report to them on the rental values of the shops. When, however, it was decided to adopt Mr. Norman Shaw's elevation, "with its heavy and cumbersome-looking pillars and arches on the ground floor," they withdrew their report, "considering that the rental values were affected adversely to a very large extent." Why? What does the rental value mean? It means the present opinion of the shopkeepers as to the suitability of the premises for their purposes. And suppose that the shopkeepers are all wrong; do not know their real interests; care nothing for the interests of the public in comparison with what they imagine to be their own; cannot see that a great architectural street is of more value as a business frontage than a mean one? They will have to be taught better; will learn better in time; and then the value will go up again. The rental value only resides in the opinion of the proposed tenants. Let them be educated into better opinions; and in the meantime let them be told that the demand for finer architecture in our streets is one in which the public at large are concerned, and that the claims of the public at large (their customers) are superior to theirs.

For half a century all persons interested in and understanding public architecture have been lamenting the mean and wretched effect of our street fronts apparently standing on sheets of plate-glass, a state of things which renders all noble and dignified street architecture impossible. We have had in Regent's Quadrant a great example of how to do something finer; are we to be debarred from seeing this carried any further because some shopkeepers cannot understand the good of it?

The one criticism that we think, with all respect to Mr. Norman Shaw, his Quadrant design is open to, is that on

sees that the upper wall-face could not be so far set back except by means of girders; that it does not stand really upon the ground floor walling. That is rather what we should be inclined to call a sham in architecture, though not half so bad a one as many that are condoned every day. He thinks differently, we suppose, and considered the effect worth the means taken to obtain it. At all events, he has got the effect, and now it must be carried out in the completion of the Quadrant, however shopkeepers may rave. They will perhaps learn some day that it was better for them.

The International Society.

THE Grafton Galleries are occupied with the twelfth exhibition of the Society which calls itself by the high-flown title "The International Society of Sculptors, Painters, and Gravers," and the exhibition consists as usual of a few good pictures amid much that is either worthless or positively ugly. Even so, the Society seems to have difficulty in maintaining its "international" character, for it has had to fill up the French contingent with loaned pictures by several deceased French painters of eminence (even going as far back as Courbet), and those by living French painters are not such as to glorify any exhibition.

Among the pictures by living artists which are worth something is Mr. Strang's portrait of Mr. Festing Jones, painted with that hard metallic texture which this painter has now adopted; but it is really not only a good likeness, but a very harmonious piece of colour, and seems like a piece of common sense among the things by which it is surrounded. His imaginative or allegorical picture entitled "Laughter" is hardly a success, and the distant landscape beyond the group of figures is poor. Among the portraits Mr. W. Nicholson's "Portrait of a Barrister" has character and individuality; and Mr. Newbery's "The Blue Scarf," a portrait of a lady in a rather *degagé* attitude, painted in a rather *degagé* style, has a certain grace and spontaneity about it. Mr. Ricketts is serious in his attempt to portray "Job and His Comforter," a fine subject in itself, but his head of Elihu is hardly a success.

What some of the contributors are about, or what they are aiming at in their preposterous concoctions, or why such things should be hung in a public exhibition, it is impossible to imagine, unless they are produced in the idea that, beauty being out of the reach of the artists, they have determined to produce an effect by sheer ugliness and monstrosity. Some of the things exhibited are beyond description in any Parliamentary language. Among the small number of works in sculpture there is one exceedingly fine marble portrait bust by Mr. Tweed. The bad example which Rodin has set of exhibiting mutilated figures shows itself in the exhibition of a torso and two partial masks of faces; and M. Rodin seems determined to fool his admirers to the top of their bent by the exhibition of his sprawling bronze figure of a nude woman in an almost impossible attitude, and modelled in the roughest possible manner. The same tendency is seen in some of the paintings; a study of a nude figure used to mean a desire to exhibit a fine and learned modelling of the figure, but that is the last thing thought of with the exhibitors at the International, where anything called "Nu" in the catalogue is generally found to be a mere splash of colour with a distant resemblance to a figure, and no modelling whatever. This kind of thing cannot, one may hope, go on for very long.

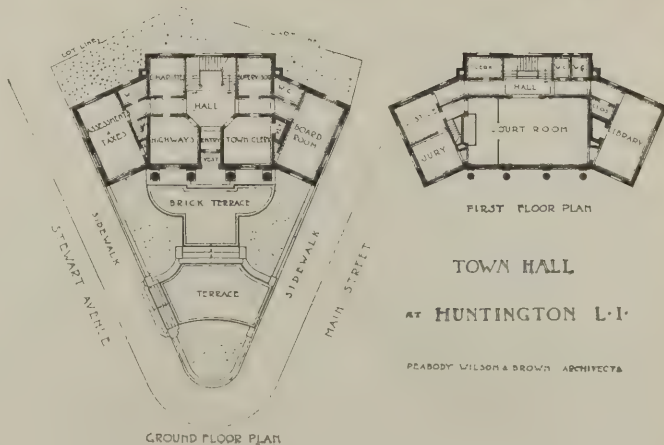

There are some good landscapes, mostly small and of rather a sketchy order. Mr. Jamieson makes an effective little picture of the octagon pavilion at the Trianon; Mr. Oliver Hall's "A Westmorland Peat Moor" is a powerful but gloomy composition; Mr. Whitelaw Hamilton's "Upland Landscape" and Mr. Peppercorn's "Near Porchester" are both good pieces of landscape composition, though the latter is no more like Nature than usual in regard to the colour and texture of trees. Mr. Cameron, in his "Badenoch," has produced a powerful effect of

evening sky behind dark mountains, but everything else in the scene is sacrificed to obtain this effect of sunset light. Both Mr. Oliver Hall and Mr. Cameron are essentially etchers, and first gained reputation as such; they are successful in dealing with landscape in black and white, but when they come to paint Nature they seem to see her mainly in black and white, and sometimes only in black.

At the end of the last room is a whole series of pen-and-ink drawings made by Mr. E. J. Sullivan in illustration of Carlyle's "French Revolution." These (something like the book itself) are not so much illustrations of fact as symbols of the state of things during the Revolution. As such they are very powerful, and quite in the spirit of the author they illustrate.

Town Hall, Huntingdon, Long Island, U.S.A.

THIS is a charming specimen, from America, of the Town Hall for a small country town. The plan is very well managed, and the placing of the side wings at an oblique angle gives a picturesque effect to the exterior without interfering with the arrangement of

the plan. The front elevation combines dignity with simple and unpretentious character. Messrs. Peabody, Wilson, and Brown are the architects. The illustrations are taken from the "Architectural Record."

Inigo Jones at Lincoln's Inn.

THE L.C.C. are securing the preservation of the façade by Inigo Jones called Lindsey House, on the west side of Lincoln's Inn Fields, in the course of any alterations that may be made on that side of the square. The front is one of Inigo Jones's quiet and dignified pieces of Classic architecture, with an order of pilasters in the upper storey; on the boundary between the forecourt and the foot-walk there are still two fine and monumental brick piers; it is stated (we know not on what authority) that there were formerly six of these piers. The idea that provision should be made for the preservation of the main internal features of the building is, we fear, rather too late; they are, we believe, all partitioned up into small offices internally; there may be some characteristic chimneypieces and ornaments left. We cannot be too careful to preserve any examples of Inigo Jones's work in London, seeing how little of it there is left.

The Architectural Association Sketchbook.

THE "First Quarterly Part, 1911," which is the official description of the last issue of the Sketchbook, starts with a rather unusual title page, the centre being occupied with a "sanguine" sketch of the profile head of Seti I., from Abydos, by Mr. W. S. George, with a marginal design symbolical of Egypt. This does not mean to imply a specially Egyptian character in the contents of the plates, as the only drawing of ancient Egyptian architecture is Mr. Palmer Jones's of the temple of Thothmes III., which closes the series, and seems an accurate but not otherwise a very remarkable sketch. The bulk of the drawings represent English work; two city churches—Christ Church, Spitalfields, and St. Lawrence Jewry—are the buildings most fully illustrated. Mr. Durnford gives a very complete and neatly executed set of drawings of Hawksmoor's church, with a note that the church and fittings have been restored to their original condition, as shown in Hawksmoor's working drawings. We should have liked to give a reproduction of the perspective drawing of the remarkable tower, which is what makes the real architectural interest of the church, but the original, in line, was too faint to make a good reproduction, nor is the plate in the sketchbook very satisfactory, as a plate. The perspective drawing is exceedingly good, but a design so powerful and unusual as this would have been done more justice to by a more powerful style of drawing. It is interesting to notice how cleverly Hawksmoor has appropriated the Gothic broach spire to a design which is altogether Classic in features, though somewhat Gothic in its freedom of treatment. The church of St. Lawrence Jewry, by Mr. Dowdeswell, is more remarkable for its detail than for its general lines, and the drawings are treated accordingly.

St. Mary's, Bottesford (Leicestershire), drawn by Mr. Cecil Sutton, has a good thin spire of a type common in Lincolnshire and Northamptonshire; the drawings are geometrical, as are those of Edington church, by Mr. Grant; both careful sets of drawings, but of a class of work which has less of interest for this generation than for the last. 14, Cavendish Square, by Mr. Hansford White, is one of the big Classic houses on the north side of the square, the façade and details of which were well worth drawing. Mr. L. M. Gotch gives a considerable number of drawings of Neville Holt, Leicestershire, including some interesting details of carpentry. The best and most effective plate in the English section of the sketchbook is that of the stairway of Waterloo Bridge, looking up, reproduced from a washed drawing by Mr. W. I. Keir; a fine drawing of a grand piece of solid masonry.

Among the foreign subjects Mr. A. G. Henderson's drawings of the Hôtel de Valois, Caen, and a view above the aisle roofs of old St. Etienne in the same town, are very good; the latter shows very effectively the curious design of the buttresses above the aisle roofs. Mr. Hepworth's large measured drawing of the west front of Rouen, double plate size, is an heroic piece of work, and must have cost much time and perseverance. Mr. Hornswell has a couple of good washed sketches of Italian bits; Mr. Prentice contributes two pen-sketches of Spanish subjects, and Mr. Palmer Jones seven drawings of subjects, chiefly Saracenic, from Egypt, besides the Thothmes drawing already mentioned; the details of plasterwork in the monastery of Surian are exceedingly interesting and unexpected in character.

"Scapa" in Japan.

WE drew attention the other day to the provisions of the new Bill for the regulation of advertisements which the Society known as "Scapa" proposes to bring before Parliament. It is interesting to learn, from a letter from Mr. Richardson Evans in the "Times" of the 9th inst., that Count Hayashi, the former Japanese Minister in London, not only returned to Japan fully imbued with "Scapa" ideas, but that the Japanese Government has lost no time, on his recommendation, in putting public advertisements under restrictions by a law which came into force early last year, and which empowers the executive to prohibit or restrict advertising display whenever it thinks such prohibition necessary for preserving the beauties of scenery, and to order the removal of any object for that reason. It has taken Japan a much shorter time to arrive at legislation on the subject than it has taken us in England; but the Japanese are an artistic nation, who are more easily aroused on such a subject than the English. And if, as we gather, there is a danger of the over-run of Japanese scenes with advertisements of the European type, we can imagine nothing more absolutely incongruous with Japanese scenes and Japanese feelings. Their Government has done wisely to take this matter in hand before it is too late.

The Glasgow Municipality and the Architects.

A LONG discussion in the Glasgow Town Council has led, we are glad to notice, to an acceptance of an amendment to throw open the additions to the Municipal buildings to public competition, by a majority of 30 to 27. It is not a large majority, but it settles the question in the right direction. In the speech of Bailie Mason, who moved that the municipal officials should be entrusted with the work, we find the usual arguments used on such occasions; an open competition would mean increased expense; the official scheme had been carefully considered by the committee; the assistant architects employed upon it had gained a premium in the London County Hall competition, and must therefore be architects of great eminence. They did not want to rival Solomon's Temple, but only to have "a good business building which would be a credit to the city." We all know what that kind of expression means; it means the production of architectural commonplace. Mr. Carlton, who moved the amendment which was ultimately carried, denied that the plans had been studied by the committee at all, and wisely urged that it was their duty to endeavour to get the very best skill they could for this work, and that in inviting competition designs they should put no restrictions on the architects, but allow them to provide their own plans as well as their own elevations; which, of course, was the only way to make the competition worth anything. One speaker said it was the duty of the Council "to countenance the ability displayed in their own office"; it does not seem to have occurred to him that the first duty of the Council was to the public, and not to their own staff. However, the amendment has been carried, and there will probably

be on that account a better chance of the new building being an architectural credit to the city. The matter is of more than local importance, for every decision of the kind tends to become a precedent in one way or another, and it is well that the tendency to have public architecture manufactured in the municipal office should be checked, for the benefit both of architects and architecture; for, as the "Glasgow Herald" pertinently observes, "the architects' protest, though no doubt embodying some perfectly legitimate professional aspirations, is fundamentally one affecting the public interest."

Factitious Rusticity.

WE notice, with rather less amusement than regret, the steady growth of a tendency to exaggerate the more primitive features of old work in reproducing them in current English domestic architecture. It is sometimes said that the acknowledged beauty of modern domestic work owes much to a return to old traditions. In a sense, this is of course true; but if it is to be interpreted as sanctioning the fashion in recent years of building interiors of houses as if they were labourers' cottages, or old-fashioned farm-houses, with crude brick grates and low ceilings carried on heavy roughly dressed beams, and furnishing them with rush-bottomed chairs and tables too heavy to be easily moved, we should reply that all this is only an affectation; it is building according to the wants and tastes of a past age, instead of according to those of the present day. If there are people who enjoy that kind of factitious rusticity in their homes, let them indulge their own tastes by all means; but it is absurd to lay it down as a rule for modern life. Rooms and furniture suitable to the refinement of a cultured society need not on that account be inartistic; they can be quite as good in that sense as cottage furniture, or better; and these drawing-rooms designed like kitchen interiors represent merely a "fad," and a rather foolish one, and we trust that architects will not yield to the temptation to encourage it. "Simple-life" architecture of this kind is, for the moment, greatly affected in America, where the slavishness with which old, crude, and inappropriate details are copied in designing modern domestic interiors is comparable to the wholesale importation into that country of Classical details for the adornment of modern or commercial public buildings.

SOME NOTABLE BUILDINGS IN BUDAPEST.

IT has been the misfortune of Austria, both architecturally and otherwise, to have been, by its situation in Central Europe, always more or less of a debatable land, where for centuries conflict constantly raged, to the detriment of the arts of peace. Consequently the country presents fewer examples of mediæval architecture than almost any other country. For many years, large portions of territory were in the possession of the Turks; and there were incessant wars, not only with Turkey, but with Hungary and Poland. Moreover, it has been remarked that, as if the ravages of war were not enough, Nature herself seems to have conspired against the stability of buildings in Austria, scarcely one of its ancient monuments having escaped earthquake, tempest, or fire.

Yet, by some extraordinary freak of good fortune, it happens that what must always have been the finest church in these dominions is the best preserved—namely, the fine cathedral of St. Stephen at Vienna, with its stately interior, magnificent spire, and graceful details; the west front, with its octagonal spire-capped towers, being a valuable example of the beautiful Danubian buildings of the thirteenth century.

Hungary was, of course, involved in the calamities of Austria, and its buildings suffered even more severely; Buda, and the greater portion of its Danubian provinces, having been, from 1541 to 1689, in the hands of the Turks, who, while they were savagely destructive of Christian buildings, left but few examples of their own architectural skill.

Austria-Hungary, however, which, next to Russia, is the largest Empire on the continent of Europe, embracing an area of 675,887 square kilometres, and containing a population of about fifty millions (the capital, Budapest, comprising about 800,000), is by no means destitute of interesting modern architecture, as the accompanying illustrations will amply demonstrate. The new city (virtually dating from 1872, when several towns were united under the present name) of Budapest, the outcome of the Constitutional Union of the two States which was first proclaimed in the Pragmatic Sanction of 1723, and was confirmed by the "Compromise" of 1867, is naturally distinguished by an atmosphere of rather extreme modernity;

for well within the last quarter of a century it has been virtually rebuilt, always with a keen eye for every detail of convenience and of comfort, which often degenerates into luxuriousness.

A peculiar item of town-planning which countries of less fortunate climatic conditions could hardly hope to emulate is the large system (inaugurated by the Hungarian Government in 1897) of planting State roads with avenues of fruit-trees—more than 800,000 fruit-trees have been planted along 6,000 miles of road, the object being to make their produce pay for the maintenance of the roads. By the same, or a similar, law it was enacted that every parish should, when possible, plant fruit-trees along its roads, and that every parish should have its orchard; and to this intent during the past ten years more than sixty million fruit-trees have been supplied from the State nurseries.

Having no architectural traditions of its own, Hungarian architecture necessarily owes much to the influences of surrounding countries; yet it possesses a strong individuality, which becomes manifest in the absorption or the adaptation rather than in the imitation of the examples to be found in Munich and Vienna. "It is," as Mr. Schuyler M. Meyer remarks in a recent article on the subject in the "Architectural Record," "precisely this conflict of traditions, of education and training, that has resulted in the most diverse and picturesquely bizarre, though often very beautiful, architectural creations."

Occasionally foreign influence has been over-strong. The Central Railway Station of Budapest, for instance, is strongly reminiscent of the former Palais des Champs-Élysées, and its environs have a distinctly Parisian atmosphere, as if they had been Haussmannised. "In Budapest one passes with prodigious rapidity from Gothic to Re-

naissance, from Italian to German, then to a Classic style intermingled with Arabic, the whole adorned with virulent colours along the borders and copings of the buildings. . . . In Vienna the houses are usually four storeys high, while in Budapest one seldom sees them over two or three; and the further one goes into the provinces from the Hungarian capital the more the height diminishes, going down to two and then to one storey. But everywhere is found the same *luxe de façade* obtained without too much dependence on foreign influence. Nor have the windows and doors in Budapest any one particular style. The variety of styles is great, but there is nothing disagreeable in the composition."

In Hungary, as in Spain, the houses are often provided with an interior court, forming a *patio*, with a balcony running round each floor. The court is sometimes covered over, and may then, upon occasion, be used as a huge dining-room. With respect to interior wall-coverings, the Hungarian is rather disposed to discard wall-paper and tapestry, and to paint his walls with simple but often very effective designs.

The park-like—almost forest-like—precinct of the Varos Liget is the most beautiful spot in the capital. It may still

THE AGRICULTURAL MUSEUM, BUDAPEST: RENAISSANCE
PAVILION.

DETAIL OF THE PALACE OF THE EMPEROR FRANCIS JOSEPH ON THE BÜRGTERASSE, BUDAPEST.

The Royal Palace was erected by Maria Theresa in 1749-71, restored in 1849 after a fire, and greatly extended during 1874-1906 by Ybl and Hauszmann. The facade towards the Danube is 1,000 ft. long, and the central part is crowned by a dome 203 ft. high, and the building contains in all 865 rooms. The equestrian statue is of Prince Eugene (Rena, Sculptor).

be described, without much exaggeration, as a "wild wood in the centre of a great city," and about its central lake are grouped the buildings of the Agricultural Museum (p. 396) by State Architect Ignac Alpár. The importance of this building is realised when one remembers that agriculture is the chief industry of Austria-Hungary, employing some fourteen millions of the people. The Museum was erected in 1902-4, and is modelled after the Romanesque, Gothic, and Renaissance buildings of the exhibition of 1896.

Among the most strikingly interesting structures of Budapest are the secular buildings in the Donauzeile, the

Calvin Platz, and the Andrássy Strasse; the Academy (1866), the National Museum, with its fine Corinthian portico, the Royal Opera House (1884), and the handsome pavilions of the Andrássy Strasse, are all in Italian Renaissance style. The Kettenbrücke (p. 395), joining Buda on the west to Pest on the east, is 1,227 ft. long and 39 ft. wide, the chains resting on pillars 160 ft. high. Two colossal lions carved in stone adorn each end. It was erected in 1849, and is one of the most successfully designed suspension bridges in Europe. It was erected by the English engineers Tiernay and Adam Clark. Three of the six bridges which cross the Danube at Budapest are suspension bridges.

The Houses of Parliament were erected in 1883-1902 from the designs of Steindl, in late Gothic style. They cover an area of 4 acres, and comprise a central block with a dome (315 ft. high), and two towers (256 ft.), two wings that are occupied respectively by the House of Representatives (south) and the House of Magnates (north). Ninety statues embellish the exterior, those on the west side representing Kings of Hungary, and those on the east Hungarian generals and statesmen. Over the chief portals are statues of Lewis I. and Matthias Corvinus. The Throne Room is a domed hall 89 ft. high, sixteen pillars supporting the dome. The Session Hall of the Representatives is 84 ft. by 77 ft. by 56 ft. high, and gives seating accommodation for 438 of the 453 members.

The National Museum (p. 396) was built in 1830-44 from designs by M. Pollak. A Corinthian portico forms the entrance on the main façade, and in front of the steps leading to it is a seated bronze figure, modelled by Strobl, of John Arany the poet.

The Royal Palace (p. 397) was erected by Maria Theresa in 1749-71, restored in 1849 after a fire, and greatly extended during 1894-1906 in the baroque style by Ybl and Hauszmann. There are 860 rooms in all. The façade towards the Danube is 1,000 ft. long, the central part being crowned by a dome 203 ft. high. To the left of the entrance to the court is the Matthias Fountain, by Strobl, erected in 1905. Of the rooms that are at present open to public inspection, the most interesting are the Large Hall and the adjoining apartments in the north wing; the Hapsburg Room under the dome; and the St. Stephen Room in the south wing, which is fitted up in the Romanesque style. In front of the central part of the palace, and facing the Danube, is a bronze equestrian statue of Prince Eugene, by Réna, erected in 1899.

THE HOUSES OF PARLIAMENT, BUDAPEST. STEINDL, ARCHITECT.

PROPOSED FLATS, UPPER BAKER STREET.

This block of flats, which the Metropolitan Railway Company are about to erect on a site at the junction of Allsop Place and Upper Baker Street, over their line, is to be a steel-framed fire-resisting building with reinforced concrete floors and 14 in. brick walls. The elevations are to be faced with purple bricks, with cherry-red rubber arches and Portland stone dressings. The flats will be decorated and finished in a substantial manner. The halls will be lined with marble and tiles. Oak joinery, automatic electric lifts, low-pressure hot-water heating to supplement the open fires, and electric lighting, will be provided.

This work is one of the many improvements now being carried out around Baker Street Station by the engineer

of the company, Mr. W. Willox, M.I.C.E. His architectural assistant is Mr. C. W. Clark, A.R.I.B.A., P.A.S.I., and the resident engineer is Mr. O. G. C. Drury, A.M.I.C.E.

COMPETITIONS.

The Weir Hospital, Balham.

From the designs submitted in the competition for the above building the trustees of the Weir Charity have selected that of Mr. R. J. Thomson, of Wimbledon.

The Federal Capital City, Australia.

The names of the adjudicators in the competition for the Australian Federal capital have been announced as follows: Chairman, Mr. J. M. Coate (surveyor); Mr. J. A. Smith, President of the Victorian

Institute of Civil Engineers; Mr. John Kirkpatrick, of Sydney (architect); and as Secretary, Mr. C. J. Clarke, of Tasmania (architect).

Miners' Federation Hall, Bolton.

Mr. Jonathan Simpson, F.R.I.B.A., the assessor in the above competition, has awarded the premiums as follows:—1st, Bradshaw, Gass, and Hope, of Bolton; 2nd, Sykes and Evans, of Manchester; 3rd, Thos. E. Smith and Sons, of Bolton. There will be no public exhibition of the designs.

LIST OF COMPETITIONS OPEN.

APRIL 20TH. ADDITIONS TO SCHOOL, DALBEATTIE.—The School Board of the Parish of Urr invite competitive plans of a proposed addition to Dalbeattie Higher Grade School of 3 class-rooms to accommodate 50 pupils each, and 3 technical rooms for wood work, cookery, and laboratory. Plans, with estimates of each of the works, to be lodged with James Little, solicitor, Dalbeattie, Clerk to the Board, not later than April 20th.

APRIL 20TH. BIRMINGHAM BLUE COAT SCHOOL.—Competition strictly limited to Birmingham architects. In a preliminary competition, three designs will be selected, and the authors will be paid £50 each to develop and redraw their plans to a larger scale, showing further details. In the event of the Governors failing to proceed with the second competition, the authors of the three designs will be paid £25 each. Assessors, Mr. C. H. Hunt, F.R.I.B.A., of London, and Mr. Charles E. Bateman, F.R.I.B.A., hon. consulting archt. to the Governors. Drawings to be delivered by mid-day of April 20th to Mr. William E. Bolton, Secretary, The Blue Coat School, Birmingham.

MAY 1ST. PAIR OF WORKMEN'S COTTAGES, RHOS RUABON.—Particulars on application to G. Meirion Griffiths, Rhos Ruabon. Raymond Unwin, F.R.I.B.A., assessor. Premiums: £10 and £5.

MAY 1ST. PUBLIC BATHS, WOMBWELL, YORKS.—Wombwell U.D.C. invite designs for swimming-baths to be erected in Hough Lane. Premiums, £40, £30, and £20. Stamped and addressed foolscap envelope to W. Quest, surveyor to the Council, Town Hall, Wombwell.

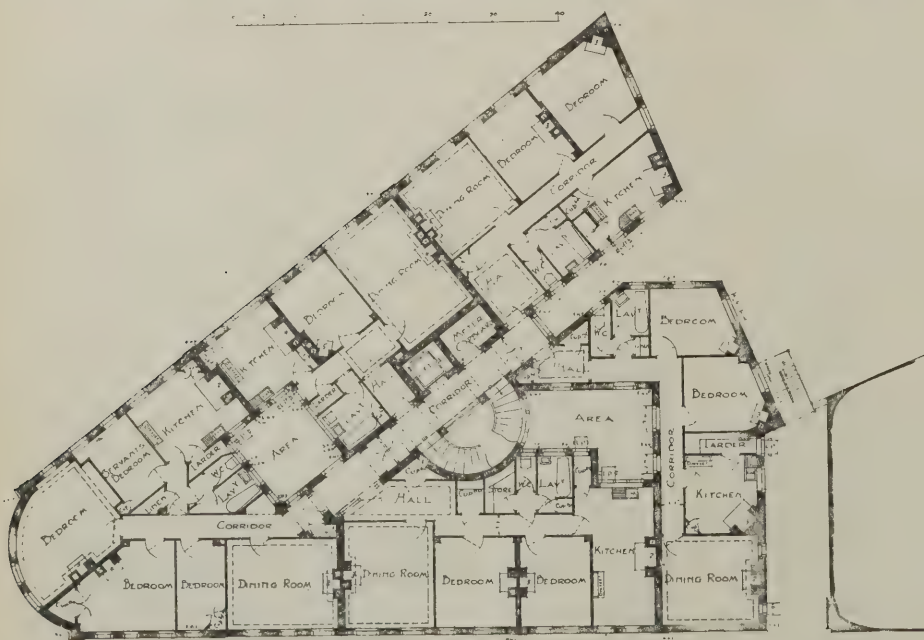

MAY 11TH. SUNK ARENA AND BAND STAND, HASTINGS.—Applications to be made to Town Clerk, Hastings. Cost limited to £4,500. Premiums: £15 15s. and £10 10s.

MAY 15TH. COUNCIL OFFICES, PORTLAND.—Portland U.D.C. offer premiums of £50 and £10 respectively for first and second designs. Particulars (deposit 10s. 6d., returnable) from R. A. Cole-nutt, Clerk to the Council, Offices, New Road, Portland. [The date has been extended from that formerly announced.]

MAY 22ND. COUNCIL SCHOOL, SOUTH-END-ON-SEA.—Local architects are invited to submit designs for above building. Conditions and plans on application to J. W. Barrow, clerk, Education Offices, Municipal Buildings. Premiums: £25, £15, and £10.

JUNE 1ST. INSTITUTE, NETHERTON, DUNFERMLINE.—Cost not to exceed £7,000. Premiums, £20, £15, and £10. Assessor, Mr. E. A. Jamieson, Apply, Secretary, Carnegie Trust, Abbot Street, Dunfermline.

JUNE 28TH. TOWN PLANNING, HALE.—Premiums of £50 and £25 are offered for a town-planning scheme.—Address Council Offices, Hale, Cheshire.

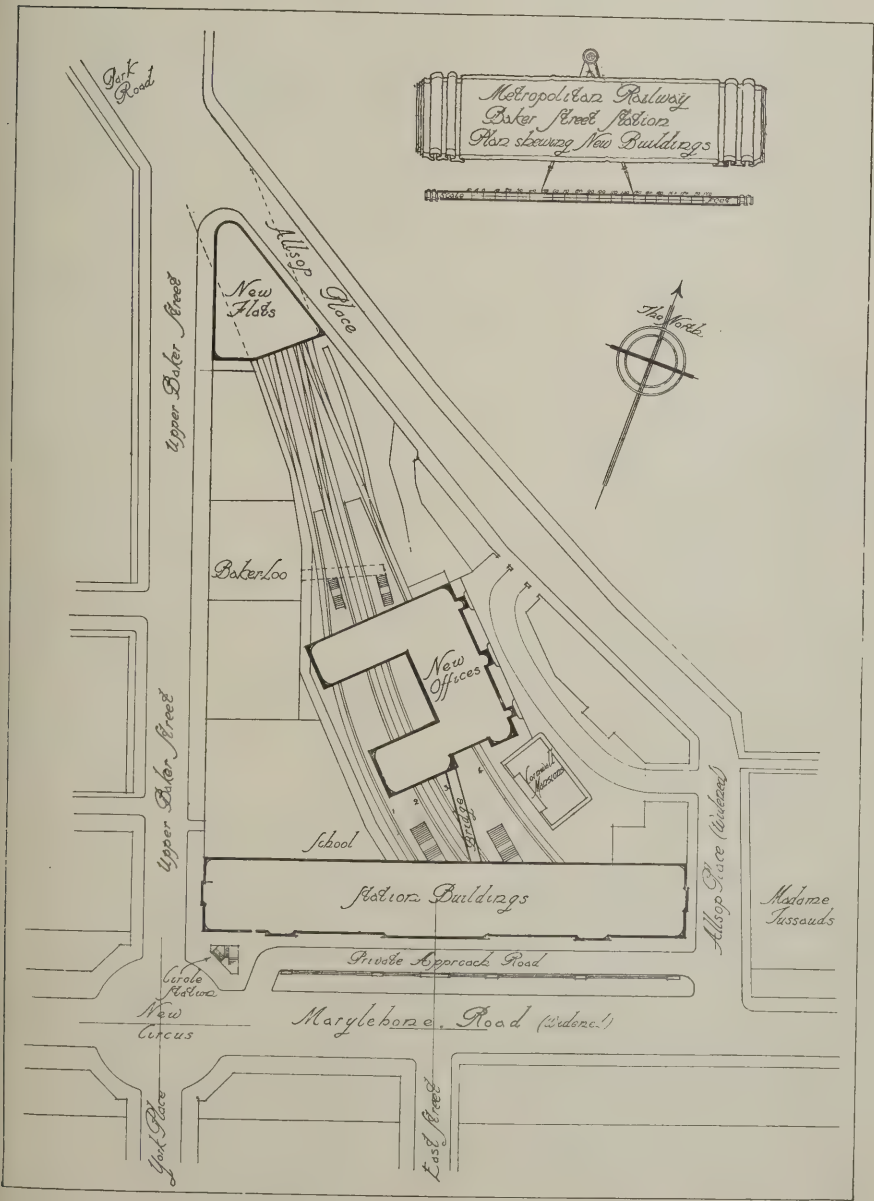

First Floor Plan

PROPOSED FLATS, UPPER BAKER STREET. W. WILLOX, M.I.C.E., CHIEF ENGINEER; CHAS. W. CLARK, A.R.I.B.A., P.A.S.I., ARCHITECT; O. G. C. DRURY, A.M.I.C.E., RESIDENT ENGINEER.

METROPOLITAN RAILWAY'S NEW OFFICES.

THE Metropolitan Railway are about to erect a large block of offices adjoining the new station at Baker Street now in course of erection, to supersede the crowded

offices at Westbourne Terrace, and to concentrate in one building those at present scattered about various parts of their system.

The chief engineer of the Metropolitan Railway, Mr. W. Willox, M.I.C.E., under whose control these various works are being carried out, has selected the system of Messrs. Edmond Coignet, of 20, Victoria Street, Westminster.

The principal dimensions of this large building, which is to be constructed entirely in reinforced concrete, are as follows: The total length of the front elevation will be 140 ft., and the height, measured from the foundations to the roof, will be approximately 90 ft. The back portion of the structure will have two wings, measuring respectively 111 ft. in length by 38 ft. in width, and 100 ft. by 43 ft. for the smaller wing, the latter being connected to the booking-hall of the new station by a footbridge 82 ft. in span, 10 ft. wide, and with a height of 15 ft.

A retaining wall in reinforced concrete and of a length of 152 ft., will run parallel to the front elevation. The total length of the retaining wall, including the returns, will be 212 ft., the height being 24 ft.

The walls of the building are to be entirely in reinforced concrete of a thickness of 6 in., and for the principal elevation the wall is to be faced with brick-work and faience.

The building will comprise a lower basement, basement, booking-hall floor, ground floor, first, second, and third floors, and a flat roof. The superloads up to the first floor included are to be 150 lb. per square foot, the second and third being 90 lb. per square foot, and the roof 40 lb. per square foot. The total superficial area of floors and roof in reinforced concrete will be approximately 65,000 square feet.

The plans here reproduced explain the arrangement. The building is to be carried on concrete stanchions over the new platforms, the lowest floor being level with the booking-hall of the new station; store and strong rooms, and the heating chamber being at a lower level and alongside a set of rails, thus facilitating the handling of the coal for heating, and the stores.

The ground floor, which is at street level, accommodates the suites of the principal officers; and the board room, which is planned between two committee-rooms and with sliding doors, can be enlarged to hold the meetings of the company. These rooms will be panelled in hardwood, with double partitions and windows to shut out any noise from the railway below. The engineer's office is placed in the north wing, so as to get the necessary light for the drawing-office.

Automatic lifts are provided in the staircase halls; the south one descending to platform level to facilitate the collection and despatch of cash, tickets, etc., the north one connecting the accountant's and other departments with the strong rooms in the basement. On the top floor are kitchens, dining-rooms, and caretaker's quarters.

The building will be heated throughout on the low-pressure hot-water system.

The architectural work has been designed by Mr. Willox's architectural assistant, Mr. C. W. Clark, A.R.I.B.A., P.A.S.I.; and Mr. O. G. C. Drury, A.M.I.C.E., is the resident engineer.

The Coignet system, which has been adopted for this work, is at present also being used for the construction of the new bridge at King's Cross Station for the same company. Messrs. Lovatt, Ltd.,

DESIGN FOR NEW OFFICES, METROPOLITAN RAILWAY, BAKER STREET, LONDON, W. CHAS. W. CLARK, A.R.I.B.A., P.A.S.I., ARCHITECT.

of Wolverhampton and London, are the contractors for the general work, and Messrs. Drew Bear, Perks and Co., for the steelwork.

The reconstruction (by Messrs. Perry and Co., of Bow) of the tunnel under Park Road, which was involved in the scheme under notice, presented considerable difficulty. Two large sewers had to be diverted without interference with their functions, and the old tunnel had to be demolished without interrupting the railway traffic. The old tunnel was of brickwork (25 ft. span), and the new covered way is being constructed with

concrete walls and steel girders with reinforced concrete between. The walls are of solid concrete from 7 ft. to 10 ft. thick, and the steel girders are of heavy section, from 35 ft. to 63 ft. span. The sequence of operations was as follows: The 6 ft. 6 in. by 4 ft. 4 in. London County Council sewer for a length of 45cft., and the 3 ft. 9 in. by 2 ft. 6 in. Marylebone Borough Council sewer for a length of 300 ft., were first diverted, and the concrete retaining walls constructed, the steel girders were erected on the retaining walls, and the old tunnel was demolished. Large gas and water mains have also had

to be diverted. The large steel girders were erected upon the site by hydraulic machinery, so as to avoid nuisance to the inhabitants by excessive hammering. For four of the illustrations (those on pages 404, 405, showing plans) we are indebted to the courtesy of the "Railway Gazette," which is published at Queen Anne's Chambers, S.W.

The elevation to the Marylebone Road is illustrated on page 403.

We hope to find an opportunity of dealing in a future issue with some of the more important features of the reinforced concrete construction.

THE MODERN HOUSE.*

BY PERCIVAL M. FRASER, A.R.I.B.A.

CERTAINLY not five per cent. of the adult population of London, the author supposed, could give a coherent statement of the essential distinctions between the architecture of Westminster Abbey, St. Paul's Cathedral, and the new Roman Catholic Cathedral. Yet it is only by general public interest in the art that architecture can make any advance. When the elegance and intrinsic beauty of design, workmanship, and finish of a structure makes a greater appeal to the general public than a mere display of ostentatious expenditure, then we can hope to obtain a more healthy co-operation between the architect and his client, to their mutual benefit.

Webb and Nesfield.

Having tabulated the factors which are essential "to the making of a complete and habitable house," and after tracing the historical development of domestic architecture, the author recalled that the remarkable efficiency and beauty of the best types of modern dwelling were first attained some 40 or 50 years ago by Philip Webb and Eden Nesfield, whose work has left a lasting impression on English domestic architecture. Then the pioneer work of Norman Shaw at Bedford Park gave the impetus to the present-day garden suburb movement.

Many others have all left their imprint on the times as having produced a series of dwellings unparalleled for their beauty and utility. Their genius has been directed also on the design of the garden, with the effect that many of these rival even the famous gardens of Italy.

What the Public Want.

With regard to the public view of modern houses, the author gave a summary of opinions which he thought might be fairly taken as voicing the general feeling on, and emphasising the striking details of, house planning.

A number of distinguished men and women were asked the following questions:—

- (1) What has struck you as the worst point about the average house?
- (2) What is the greatest improvement you have met with in building or in the fittings?

Among those who contributed replies were: Thomas Hardy, Sir Edward Poynter, Arnold Bennett, H. G. Wells, Sir Arthur Pinero, J. K. Jerome, Hall-Caine, Mrs. Despard, Israel Zangwill, Hiram Maxim, W. W. Jacobs, and others.

The opinions put forward in answer to those two questions may be summarised respectively as follows:—

- (1) Worst Points.—The large hall for a small house being unsuited to English requirements. The open heating arrangement, which makes portions of all rooms uninhabitable. Ventilation primitive. Sliding sashes (these should be superseded by casements with transoms and top lights). Basements, a great evil. Cupboard accommodation always inadequate. Windows too small and used without discrimination. Smells permeating the house from the kitchen. The continual labour entailed by stone steps and polished metal fittings. No proper accommodation in rooms for furniture.

*Extracts from a paper read before the Institute of Sanitary Engineers.

REBUILDING SCHEME FOR THE BAKER STREET STATION OF THE METROPOLITAN RAILWAY: ELEVATION TO MARYLEBONE ROAD.
W. WILLOX, M.I.C.E., CHIEF ENGINEER; CHAS. W. CLARK, A.R.I.B.A., P.A.S.I., ARCHITECT; O. G. C. DRURY, A.M.I.C.E., RESIDENT ENGINEER.

The principal dimensions of this building, which is to be constructed entirely in reinforced concrete, are as follows:—Total length of front elevation, 140 ft.; height from foundations to roof, about 80 ft.; two wings of back portion, 111 ft. by 38 ft., and 100 ft. by 43 ft., respectively; the smaller wing being connected to the booking hall of the new station by a footbridge 82 ft. in span, 10 ft. wide, and 15 ft. high. The walls of the building are to be in reinforced concrete 6 ins. thick, the principal elevation to be faced with brickwork and faience; the design being in a free classic manner suitable to the materials. The building will comprise lower basement, booking-hall floor, ground floor, first, second, and third floors, and a flat roof.

(2) Improvements.—The arrangements of a bath and lavatory basin directly available from each bedroom. The discriminate use of folding doors. The employment of double walls, affording even temperature. The centralisation of the heating system. Methods employed to conserve waste water for garden purposes. The great development in thin, light, cheap and sound-proof partitioning. The designing of details to avoid lodgement of dust.

In addition to the foregoing, the following may be quoted: Sir Arthur Pinero congratulates the sanitary engineer as being responsible for the best modern improvement in houses. Hall Caine says: "Architects are as important as doctors to the health of a nation." Mr. Robertson Scott says: "The fundamental fault is that houses which are to be lived in most of the time by women, and are wholly worked by women, are planned by men who are chiefly single men." Sir Frederick Treves says: "England's worst feature is the typical suburb, whose streets have one feature only—namely, 'ugliness.'" He comments adversely on the usual bad conditions under which domestic servants live. W. W. Jacobs says, with characteristic humour: "All I know is that the average house is hideously ugly, both inside and out, and that people, generally speaking, like them."

Mr. H. G. Wells, in his novel "Kipps," has a good deal to say with regard to the modern house. He says that "Houses to-day are built on the ground of monstrously rich and shabbily extortionate land owners by parsimonious greedy people in a mood of elbowing competition." As a consequence, there are very few nice little houses. The plans are invariably inconvenient; floor boards yawn open, and are too splintery to scrub; and there are acres of stone steps to clean.

Mr. Fraser, while giving the foregoing as the prevailing public opinion on matters of domestic architecture, desired to disassociate himself from many of the views put forward. He then summarised the acknowledged essentials of the well-planned house, and proceeded to deal with lighting, sanitation, by-law requirements, etc. Afterwards he proceeded to treat of the subjects indicated by the following headings:—

Materials of Construction.

The great modern defect of house-building is the use of a heterogeneous mixture of materials brought from great distances at considerable cost merely to obtain outward effect. There is no doubt that the hidden charm of most old buildings lies in their fitness and right to be where they are. When one meets with a house costing, say, £800 to £1,000, it is obvious that no money should have been wasted in extravagances. It therefore jars unpleasantly on the senses to find a red brick plinth with a cement skirting, a stone cap to the plinth, rough-cast walls with stone dressings, the front gable half-timbered, the side gable tiled and the back gable filled in with elmboards, window-sills of Austrian oak, the beam across the bay window a rolled steel joist covered in plaster, pitch-pine balusters, mahogany handrail, European pine for the ceiling rafters, Persian tiles for the fireplace, French enamel on the joinery, a Yankee stove in the hall, and the roof covered with stone slabs, and so forth, *ad nauseam*. This is no exaggeration; it may be met with in a more or less

marked degree in the majority of small modern houses. The extraordinarily fine effects which can be obtained from local materials he showed by means of lantern slides

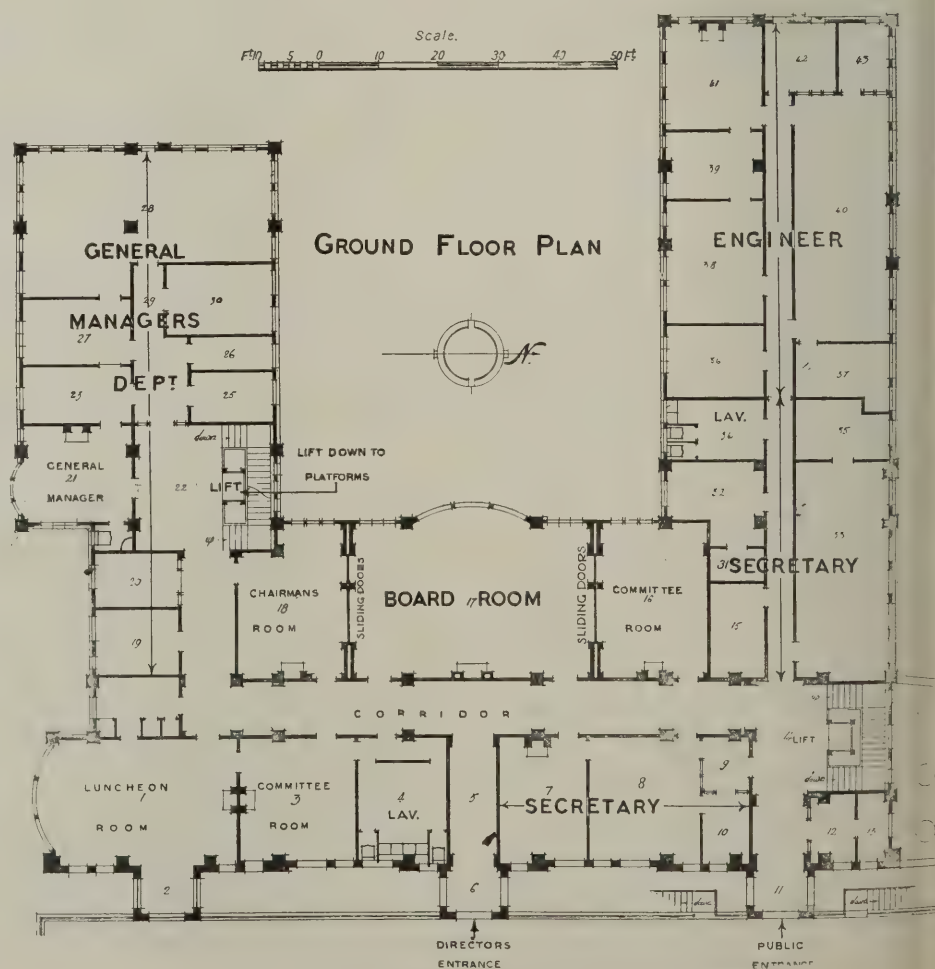

Site, Prospect, and Aspect.

The question of aspect and prospect is inseparably bound up with the selection of the site. The general public have much to learn with regard to these comparatively simple questions. It must be remembered that unless extraordinary precautions are taken, a house will draw up from the ground all gases which are near the surface, and in the many cases where no protection is afforded by covering the site with concrete or other means taken, cholera, dysentery, typhoid, and other dangerous complaints have been prevalent. Dampness is drawn from the soil by the warmth of the building. It is obvious, then, that a site should be chosen which is likely to be free from exhalations of dangerous gases, and where the ground water is at a low level or the soil light. Statistics show beyond question that the drier the soil the less prevalent is pulmonary consumption, a very common complaint. London consists in a large measure of sites which have been filled up several feet to bring to a convenient building level. Filling-up material may either be clean soil or town refuse, but in both cases will contain organic matter. The dangerous properties of such filling-up material need not be expatiated on, therefore avoid made-ground, clay soils, and low-lying or damply situated sites. The ideal site is on a gentle slope facing nearly due south-west by south, with trees a fair distance. The house should be towards the highest part of the

slope, to be away from the valley mists, but not so high as to be exposed to prevailing winds. In choosing a site which may be well wooded, do not hew down trees without careful consideration. Endeavour to find a spot which will permit of as little of this savage vandalism as possible. In theory it is bad to have trees around the house; but it is not so bad as faddists would have one believe. They protect from driving rains, and they must certainly add to one's sense of comfort, and are such a continual source of delight that the disadvantages are altogether insignificant in most cases. A north aspect is cold and damp. An east aspect is cold but dry. A south aspect is the most desirable, being warm, dry, and bright. The west is generally not cold, but wet and windy. Of two sites of equal merit, choose that which is not rectangular. Nothing gives one so unpleasant a sense of restraint as to be surrounded by four fences meeting each other at right angles, like a sheep-pen.

A beautiful house has a refining influence, and assuming that the architect is competent to turn out a sound design, his employer may rely on coming round in time to his architect's idea of what is beautiful.

The gardens should be planned at the same time as the house, so that trees can be planted as early as possible where they will protect the house and not encroach on its light and air. It is of great importance to settle the levels of the ground so that the house may not be in a hollow. If the garden is laid out in due time, prospects from the windows which are not quite happy may be ameliorated. Imagine the house in

METROPOLITAN RAILWAY OFFICES, BAKER STREET, W.

November, and do what you can to render the living rooms pleasant in outlook for the dreary months.

Planning.

The modern house is so complicated an undertaking that the very greatest and most minute consideration is required to harmonise all the elements and crystallise them into a simple and obvious plan, and the smaller the house the greater difficulty it presents. A really convenient plan is worth a vast amount of trouble. Supposing a house is so inconveniently planned that an extra maidservant is required, this means an increase on the annual expenditure of about £60, representing a capital of, say, £1,000.

Dark kitchen offices will be dirty, and you will not be able to see the dirt, which makes matters worse for everybody. Do not condemn your servants to live in underground dungeons. Your work and wage bill will suffer, for supervision becomes arduous. Remember that to walk upstairs 10 ft. from floor to floor requires as much energy as to walk 200 ft. on the flat. Working on the reasonable assumption that a housemaid living in the basement has to make thirty journeys per day to the ground floor, this is equivalent to about a mile's walk on the flat, to say nothing of the extra strain occasioned by the violent exercise.

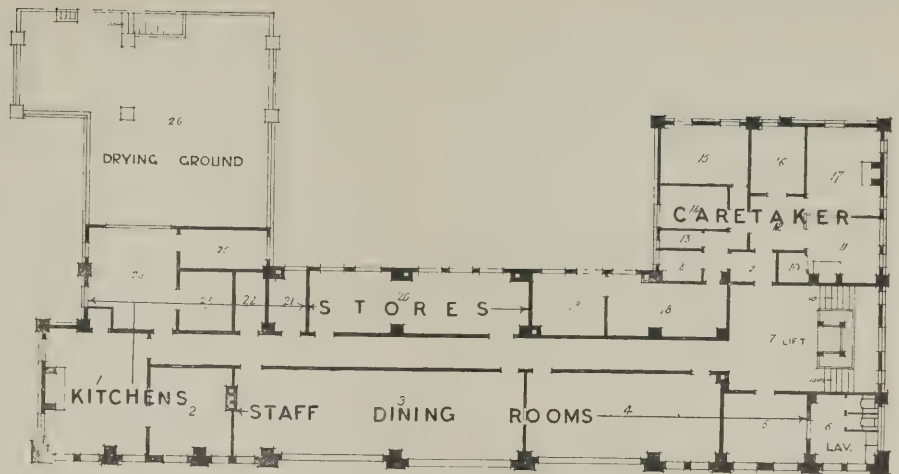

The English nation are peculiarly a home-loving people, fond of seclusion and independence. Some decent deference is due to the occupants of the adjoining site when one builds a house. Care should therefore be taken not to overlook your neighbour if this can be reasonably avoided.

A really good plan can only be evolved by the intelligent co-operation of the owner and the architect, and before this is settled on, the furniture should be imagined in position in the rooms; and it is astonishing what material alterations this will sometimes entail for a conscientious designer. An architect should be indulgent to his client's fads. It is said that all comfortable people have fads, but a sensible architect will take it for granted that his fads are entirely his own business and should not be forced on his clients.

The kitchen range and scullery fittings should in no circumstances be cheap, and they should be well arranged. The preparation of food is a most important function, and every facility should be afforded to acquire good results. It cannot be expected that foods can remain sound and healthy when stored in improper places. The cook cannot maintain a proper standard if the kitchen and scullery equipment is defective.

The building owner who prefers a lavishly decorated drawing room to well-equipped kitchen offices is vitally injuring himself, and is laying out his money to bad advantage. The kitchen and scullery should both be adequately ventilated at the ceiling level. The earthenware utensils of the kitchen are best leadless glazed. Meat dripping, for instance, will dissolve the glaze on lead-glazed utensils, and has been frequently known to set up mild forms of lead poisoning.

With regard to general construction, it seems superfluous to say that the whole of the materials throughout should be of ample strength, but it is very rarely that one finds a house which gives a com-

THIRD FLOOR PLAN

SECOND FLOOR PLAN

FIRST FLOOR PLAN

METROPOLITAN RAILWAY OFFICES, BAKER STREET, W.

fortable sense of solidity. The size of the floor joists may be sufficient to carry the superimposed weight, but unless there is an ample margin of strength such a floor will always creak and vibrate; it will be noisy, and the ceilings below will show unsightly cracks.

Thin walls are a prolific cause of coldness, dampness, and ill-health. The minimum thickness in this country should be fourteen inches, and the best arrangement is to construct the walls in two thicknesses with an air-space between. It has been demonstrated to be possible to blow out a candle through an ordinary 9-in. wall, thus proving the extreme porosity of brickwork. The cheap brick will absorb water to such an extent that the average ten-roomed house could absorb as much as 10,000 gallons of water. The application of plaster or rough-cast or plaster to the outside is not quite efficacious, although it is of considerable help. The effect of thin walls is to chill and moisten the air of the interior. This will result in the occupants blocking up the means of ventilation in order to obtain warmth.

The paper concluded with some observations on general hygiene, and on the care and upkeep of the house. The discussion which ensued did not bring out any fresh points of importance.

LABOUR UNREST IN THE BUILDING TRADE.

The dispute which arose between masters and men in the London building industry towards the close of last year still remains unsettled. The Amalgamated Society of Carpenters and Joiners, representing several branches of the trade, sent in their notices in December last. As this union has to give six months' notice of a desire to terminate an agreement with their employers, these notices will take effect on June 8th, if an arrangement is not come to before then. The matters in dispute are the rates of wages and the hours of work. Wages, the men's representatives state, were settled at 10½d. an hour in 1900, and there had been no increase since then, although the cost of living had increased enormously. Consequently the workmen are now asking that they should be paid 1s. an hour. They are also asking for a reduction of summer hours of working, and for double pay for overtime. At present the working hours were fifty a week, and they are asking that it shall be reduced to forty-seven. The men are arranging a mass meeting to take place in Trafalgar Square on May 5th.

About 15,000 carpenters in Chicago have struck for increased wages, and building operations to the value of £7,000,000 are affected. The union carpenters of Des Moines (Iowa) have also ceased work, and the movement threatens to spread.

Demands by the workmen of Cardiff are under consideration by a committee of the Master Builders' Association. The carpenters are asking for a penny an hour increase in wages, that the finishing time on Saturdays be 12 o'clock instead of 1, and that the day just before and after Christmas commence at 7.30 a.m. instead of 8 a.m., and that breakfast be taken during the work day. The masons are also asking for an increase in wages, and demands by all sections of the trade are being made on similar lines.

PROFESSIONAL PRACTICE, AND A SUGGESTED CODE OF ETHICS.*

BY C. McARTHUR BUTLER, F.C.I.S.

Mr. McArthur Butler's suggestions for a code of ethics for architects were avowedly drawn up with the object of eliciting opinion and promoting discussion on the subject, and should obviously be read in that light.

FOR some time the Council of the Society of Architects have had under consideration the question of drafting a Code of Ethics relating to matters of professional etiquette in the architectural profession, and it was thought the importance of the subject warranted its being brought before the members with the view of eliciting opinion thereon, and if possible, of formulating some basis on which further action might be taken by Council of the Society.

In going into the matter Mr. Butler found that the information then in his possession regarding the question in relation to professions generally was inadequate to enable him to deal usefully with the subject, and therefore, as a first step, he approached some fifty societies connected chiefly with architecture, engineering, and the allied professions at home and abroad, but including also a few institutions representative of other callings.

Custom in Other Professions.

I need only refer in passing to the professional etiquette prevailing in such professions as those of Law and Medicine, the code applying to the latter being probably one of the most stringent, so much so that from a perusal of letters in the public press, one is led to think that the line may sometimes be drawn to an extent which might appear to amount to an injustice in certain cases. Among the numerous institutions representing the engineering, surveying, and allied professions in the United Kingdom, the only one, so far as I am aware, which has a code of ethics as well as by-laws, is the Institution of Civil Engineers, whose procedure in this respect is being closely followed by the Institution of Electrical Engineers, and by the newly formed Association of Consulting Engineers. I understand that the American Engineering Institutes adopt similar methods.

The opinion has been expressed that in some cases, as, for instance, where an institution is called upon to act in a judicial capacity in dealing with complaints regarding professional etiquette or misconduct, a code might limit and hamper that institution in the performance of these duties, but the general feeling appears to be in favour of a code.

The Attitude of Architectural Societies.

The American Institute of Architects offers to its members advice relating to the principles of professional practice, and puts forward a canon of ethics. The architectural institutions of Australia are co-operating in compiling a code, while the one issued by the Central Society of French Architects, has been adopted by other French architectural societies. In South Africa, similar measures are being adopted by the various associations of architects, following the successful efforts which have been made in that country in regard to the registration of architects, a matter in which the Society of Architects, through its South African branch, played no inconsiderable part.

*Extracts from a paper read before the Society of Architects, April 11th.

In Canada, the Royal Architectural Institute of Canada and other associations of architects, which are rapidly springing up in that progressive dominion, have each their code of ethics, administered in most instances, I believe, under an Act of Parliament.

Suggestions for a Remedy.

In my opinion, the desirability in principle for a schedule of principles of practice, and a code of ethics, is admitted, and what is good for the societies concerned may be held to be good for the profession generally.

Here, however, we are faced at once with the difficulty of dealing with that considerable body of architects outside any architectural society, who possibly could not be expected and certainly could not be obliged to adhere to any general schedule or code, nor against whom could such a code be enforced in the absence of any controlling body representing the whole of the profession and vested with statutory powers.

A Board of Professional Control.

In the absence of, or in the anticipation of, such a controlling body as would be constituted under a Registration Act, I suggest the immediate formation, by agreement between the architectural societies, of a Board of Professional Control, representing every architectural society in the United Kingdom in such proportion as may be arranged.

This Board would have no power to interfere in the domestic policy or procedure of the societies concerned, but would act after due deliberation, with the weight of combined authority, on any questions of public or professional interests, and might also act as an appeal or advice court if required to do so by any architectural society in regard to any question affecting that particular society.

By this means pressure could be brought to bear both on public bodies and members of the profession, much more efficiently than under the present system, while it would be very difficult and highly undesirable for even the unattached architect to ignore the fiat of a body so constituted; indeed, in my opinion, one effect of the formation of such a body would be to encourage those outside to come into one or other of the societies.

SUGGESTIONS AS TO SOME MAIN PRINCIPLES TO BE OBSERVED IN ARCHITECTURAL PRACTICE.

The Architect in Relation to his Client.

(1) *Status.*—The architect's relation to his client throughout the entire course of his services is primarily that of a professional advisor, but an additional relation is created when the architect is made the interpreter of a contract between his client and a contractor, though the fact that the architect is paid by the client does not invalidate his obligation to act with impartiality.

(2) *Drawings and Estimates.*—The architect provides preliminary drawings and estimates when required, but if an unconditional limit of cost is imposed before the contract drawings are prepared, he must be free to make such variations from the preliminary plans as may be necessary. It is desirable in regard to works of any importance that a specific agreement be come to with the client before the signing of the contract, regarding the ownership of the drawings and other documents or the supply of a duplicate set, at the expiration of the work.

The architect should not by bond or otherwise guarantee an estimate or contract.

(3) *Superintendence.*—On all work except the simplest, it is to the interest of the client to employ a superintendent or clerk of the works, and in certain cases to retain also the services of experts. These persons, although paid by the client, should be selected by the architect under whose direction they are to work.

(4) *Charges.*—The schedule of charges as approved by the Board of Professional Control is to be the minimum of payment to the architect, and as circumstances may justify a higher charge it is desirable that the charges be agreed between the parties before the work is put in hand.

The architect may not compete in regard to fees, or undercut to secure work.

(5) *Payments.*—The architect shall not be the medium of payment made on behalf of his client except by special agreement, but shall only issue certificates or recommendations for payment by his client.

(6) *Expert and Honorary Services.*—The architect, when retained as an expert, should receive payment proportionate to the responsibility and difficulty involved. Experts should not knowingly name prices in competition with each other.

The architect should not perform work in an honorary capacity except for charitable purposes approved by the Board of Professional Control.

(7) *Tenders.*—In advising that none but trustworthy bidders be invited, and that the contract be given only to persons who are reliable and competent, the architect protects the interest of his client.

THE ARCHITECT IN RELATION TO THE CONTRACTOR.

(8) *Contractors and Craftsmen.*—As the architect decides whether or not the intent of his plans and specifications is properly carried out, he should see that these documents are complete and accurate, and should not call upon the contractor to make good oversights or errors in them, or attempt to shirk responsibility by permitting indefinite clauses in the contract or specifications.

While he must condemn bad work, he should commend good work, and intelligent initiative on the part of craftsmen and other workmen should be recognised and encouraged.

THE ARCHITECT IN RELATION TO THE PROFESSION.

(9) *Building Trades.*—The architect should not directly or indirectly engage in any of the building trades, nor be a party to any building contract except as owner. If he has any financial interest in any building material or device he should not specify or use it without the knowledge and approval of his client.

(10) *Offering Services.*—The seeking out of a possible client and the offering to him of professional services on approval and without compensation, unless warranted by personal or previous business relations, tends to lower the dignity and standing of the profession and is to be condemned.

(11) *Advertising.*—Advertising tends to lower the dignity of the profession, and is therefore condemned, as is the display of the architect's name upon a building under construction, but the unobtrusive signature of buildings after completion is approved by the Board of Professional Control.

The use of initials designating membership in any architectural or similar society is proper in connection with any professional service, and is to be encouraged as helping to make known the nature of the honour they imply.

(12) *Competitions.*—The Architect should not take any part in a competition unless it be conducted according to the best practice and usage of the profession as formulated by the Board of Professional Control. Except as an authorised competitor he may not attempt to secure work for which a competition has been instituted. He may not attempt to influence the award in a competition in which he has submitted drawings. He may not accept the commission to do the work for which a competition has been instituted, if he has acted in an advisory capacity either in drawing up the programme or in making the award. He shall not submit any drawings in any competitions, other than those designed and prepared under his personal supervision, nor attempt to secure any work for which a competition remains undecided.

(13) *Injuring Others.*—The architect should not falsely or maliciously injure, directly or indirectly, the professional reputation, prospects, or business of a fellow architect, nor criticise in the public Press the professional conduct or work of another architect, except over his own name.

(14) *Supplanting Others.*—The architect should not undertake a commission while the claim for compensation or damages or both of an architect previously employed and whose employment has been terminated remains unsatisfied, unless such claim has been referred to arbitration or issue has been joined at law; or unless the architect previously employed neglects to press his claim legally; nor should he attempt to supplant a fellow architect after definite steps have been taken toward his employment.

(15) *Membership in Societies.*—As it is only by co-operation and by the personal interchange of views and opinions that the profession can as a body exercise an influence on the art and on public opinion, and its members be brought into better relations the one with the other and with one another, an architect should qualify for and join and encourage his subordinates to do so, any local architectural society and also and in any case, one or other of the larger and more representative societies, and should take an intelligent and active interest and part in their proceedings.

Should such a course not appeal to him from a personal viewpoint he should look at it from another, that of joining a society not for what he can get out of it, but for what he can put into it, for the general good.

(16) *Duties to Pupils.*—As the qualifications for the practice of architecture should

be based on general education as well as on technical and professional training, the architect should so advise intending students, and give pupils and assistants every facility and encouragement to avail themselves of educational facilities, and support to the best of his ability all recognised architectural educational bodies and professional societies.

The architect should not undertake the training of a pupil, nor take more than one pupil at a time, unless he has the proper facilities, scope, and opportunities for giving him, or them, personal oversight and instruction.

THE ARCHITECT IN RELATION TO THE PUBLIC.

(17) *The Public and Building Authorities.*—The architect should be mindful of the public welfare and of his duties as a citizen, and should participate particularly in those movements for public betterment in which his special training and experience qualify him to act. He should not, even under his client's instructions, engage in or encourage any practice contrary to law or hostile to the public interest, for as he is not obliged to accept a given piece of work, he cannot by urging that he has but followed his client's instructions escape the condemnation attaching to his acts.

The architect should support all public officials who have charge of building in the rightful performance of their legal duties. He should carefully comply with all building laws and regulations, and if any such appear to him unwise or unfair he should endeavour to have them altered.

(18) *Professional Qualifications.*—The public has the right to expect that he who assumes the title of architect has the knowledge and ability needed for the proper conception, presentation, and supervision of all building operations which he may undertake.

Suggestions for a Code of Ethics, the violation of any items of which should constitute unprofessional conduct.

The following items are suggested as a guide, but their enumeration should not be construed as a denial of the existence of others equally important; and just as the several items indicate offences of varying degrees of gravity, so the penalty for infringement would involve warning, reprimand, expulsion, or such other punishment as the Board of Professional Control may at the time decide.

It is Unprofessional for an Architect—

(1) to engage directly or indirectly in any of the building trades, except as owner; (2) to guarantee an estimate or contract by bond or otherwise; (3) to accept any commission or substantial service from a contractor or from any interested party other than the client; (4) to advertise; (5) to take part in any competition the terms of which are not in harmony with the principles approved by the Board of Professional Control; (6) to attempt in any way, except as a duly authorised competitor, to secure work for which a competition is in progress; (7) to attempt to influence either directly or indirectly the award of a competition in which he is a competitor, or in which he is interested in any other capacity; (8) to accept the commission to do the work, either personally or by partnership, for which a competition has been instituted if he has acted in an advisory capacity either in drawing up the programme or in making the award; (9)

to injure falsely or maliciously, directly or indirectly, the professional reputation, prospects, or business of a fellow architect. (10) to undertake a commission while the claim for compensation or damage, or both, of an architect previously employed and whose claim has been referred to arbitration, or issue has been joined at law, or unless the architect previously employed neglects to press his claim legally; (11) To attempt to supplant a fellow architect after definite steps have been taken toward his employment; (12) to compete knowingly with a fellow architect for employment on the basis of professional charges; (13) to criticise in public print the professional work or conduct of another except over his own name; (14) to deviate from the scale of charges without permission of the Board of Professional Control.

General Observations.

There are five points in particular arising out of the proposed Schedule of Practice and Code of Ethics to which I would call attention: (a) the ownership of drawings; (b) scale of charges; (c) advertising; (d) competitions; (e) architectural societies; (f) public authorities.

In regard to (a), the ownership of drawings. The fact that an architect can be called upon to deliver up to a client all drawings and documents on completion of the work and payment of fees, in the absence of any express agreement to the contrary, renders it desirable in my opinion to consider the question of endeavouring to get the decision in "*Gibbon v. Pease*" reversed, and in the meantime, in works of any importance, for the architect to arrange procedure with the client previously.

In regard to (b), the scale of charges. The fact that the only authority and recognition which this scale has is based on custom renders it desirable in my opinion from this point of view to hasten an Act of Parliament under which such a scale would be legalised. On the question of the scale generally, I am of opinion that in the architectural profession payment by commission on the cost of the building is wrong in principle if not immoral, as it is exceedingly difficult to get away from the fact that the architect benefits materially in proportion to the amount spent by the client, though he may and does in the interest of his client, make every endeavour to keep within the limit laid down. The architect should not in my opinion be placed in a position where it may be inferred that his personal interests are likely to clash with those of his client. Again, a minimum scale is not unlikely to be considered or to become a maximum one also. I have no practical proposal to make at present for the redrafting of the scale as it now exists; but it has been suggested to me, why have a scale at all, why should not architects, like other artists, adjust their charges in accordance with what they can command for their services?

In regard to (c), advertising. It all depends on the interpretation and definition of the term, which I take it is intended to mean when applied to architects, that they should not employ commercial methods of making themselves and their work known to the public, that is to say by direct advertising.

As to indirect advertising, an architect, like any other professional man with any considerable practice, can hardly avoid it. His name is constantly brought before the public in the professional journals and by the technical papers, by the books or papers he publishes, to say nothing of his name and address on

announcements on sites for public buildings, for which publicity if he sought it through the usual channels he would have in many cases to pay a heavy charge.

In regard to (d), competitions. It has been urged upon me with considerable force and frequency by members of the Royal Institute as well as others, that the restrictions very properly laid down by the R.I.B.A., and endorsed by the Society, should not altogether apply to small local or limited competitions. The reason for instance that an assessor is not always appointed is not invariably that the persons concerned do not agree in principle to such a course, but is sometimes due to the financial margin being so small that it will not justify the considerable expense involved in the appointment of an assessor, and if the local architects concerned are satisfied and willing to compete on the terms laid down by the promoters, it is suggested they should not be unduly penalised, under the present conditions prevailing in the profession, where if an architect is loyal to his society and refrains from competing, he leaves the field open to others who for reasons previously stated are under no control or obligation.

In regard to (e), architectural societies. One has to allow for human nature, which in this case usually takes the form of joining a society for personal benefit and making use of it for one's personal ends, though I am bound to say from experience that the other point of view has occasionally prevailed, the possibility of there being any other than the personal view not having previously occurred to the person concerned. I may here say that in the Dominion of Canada membership in local associations of architects is compulsory by law on those who desire to use the title of architect.

In regard to (f), public authorities. The architect sometimes finds himself hampered with the requirements of by-laws and building regulations, or of those of the officials whose duty it is to administer them, but his efforts will of course be directed to complying with the requirements of lawfully constituted authority, and to find a remedy for his grievances (if any), not in endeavouring to evade but to amend those regulations which appear to him to be irksome and unnecessary.

It only remains for me to say that the opinions I have expressed are personal to myself, and are put forward for the purpose of eliciting criticisms or suggestions, and only to the extent to which they may subsequently be endorsed by those concerned must they be taken as representing the views of the Council or of the Society of Architects.

TEMPERATURE REGULATION IN BUILDINGS.

In a paper on "Automatic Temperature Regulation" read before the Institution of Heating and Ventilating Engineers by Mr. Herbert A. Jones, the author remarked that in this country the question of automatic temperature regulation had up till quite recently failed to arouse interest on the part of owners of buildings, their architects or consulting engineers, although such systems were in extensive use in the United States, Canada, and other countries, and were there regarded as just as much a necessity in the equipment of a building as the heating system itself. Automatic control was just as

much a necessity and as desirable here, in spite of the fact that we did not get great variations of outside temperature. Those who had been in the United States and Canada had probably been struck with the comparative comfort with which they could withstand the extreme cold of the winters; this was due to the dryness of the air. On the other hand, they had all met the American who complained that he could not keep warm here in winter. These experiences were proof that small extremes of temperature in a climate that had large extremes in humidity, or variations in the amount of moisture in the air, were possibly more uncomfortable to experience than great extremes of temperature where the humidity was more constant. As the atmospheric humidity of the United Kingdom was notoriously great and variable, and since this, with our average and uncertain variation of winter temperature, was thus proved to have such an effect on the comfort or otherwise of the community, the subject of automatic temperature regulation was worthy of the very careful consideration of all those concerned in the design and equipment of public buildings, schools, etc.

The subject of temperature regulation was frequently confounded with ventilation. The latter dealt with the supply of fresh air, while the former controlled the temperature and prevented the rooms of a building from becoming too hot or too cold. The advantages derived from temperature regulation were twofold:

(1) By keeping the temperature of a building (say a school) at, say, 60°, all waste of fuel was prevented, and consequently a considerable saving of money was effected. Hundreds of pounds had been wasted in a single school by overheating it and securing a cooler temperature by opening the windows. Every particle of excess heat which went out of the windows was an actual waste of money. If the outdoor temperature was 30° it would require 30° of heat to bring the schoolroom temperature up to 60°. If, however, the outdoor temperature was 50°, only 10° of heat were required to ensure the comfort of the schoolroom. A trustworthy system of temperature control would furnish the exact amount of heat required and avoid all excess consumption of fuel, and consequently save money.

(2) By keeping the class-rooms at an even temperature the health and comfort of teachers and pupils were promoted. A class-room that was too cold caused physical discomforts which might result in ill-health. A class-room that was too hot was even worse. The average teacher would resort to an open window for relief. The draughts from these windows were certain to bring on coughs and colds, which only too frequently ended in throat and pulmonary troubles. The cause of education was as much promoted by hygienic surroundings and physical comfort of pupils as by teachers and textbooks. Hence automatic temperature regulation for schools was becoming regarded by the highest experts in this country as a necessity.

In the concluding part of the paper the author gave a brief description of several systems which could properly be described as attempting to give temperature regulation. The requirement was an apparatus which, fixed in the position where it got an average temperature, was affected by the same, and controlled some distantly placed valve or other mechanism through which the source of heat passed.

THE APSE OF THE MADELEINE, PARIS.

DRAWN BY A. C. CONRADE.

THE HALLS OF THE CITY COMPANIES.

In the "City of London Year Book and Civic Directory" (London: W. H. and L. Collingridge, Aldersgate Street, E.C.), there is a concise account of each of the City Companies. Each company has its hall; and as these buildings usually possess considerable architectural interest, it will be useful to extract a few particulars of some of the more important of them from this directory, supplementing the details, here and there, with information from other sources. The companies are taken in alphabetical order.

The hall of the Society of Apothecaries was founded in 1623, and the building was destroyed in the Great Fire of 1666. The present building was erected in 1670-6. It is in Water Lane, Blackfriars, and reputedly occupies the site of the theatre that was jointly owned by Shakespeare and Burbage.

The Armourers and Brasiers' Company's hall is at 81, Coleman Street. The old hall was built by W. Creswell; the architect of the present hall, which was built in 1839-40, was Mr. Joseph Henry Good.

J. Elmes renovated the hall of the Bakers' Company, 16, Harp Lane, Great Tower Street, which was built, after the Great Fire of 1666, on the site of the ancient residence of John Chichley, Chamberlain of London.

Inigo Jones built, in 1636, the ancient hall and theatre of anatomy of the Barbers' Company, in Monkwell Street, Falcon Square. The hall was rebuilt in 1668, after destruction in the Great Fire, when, however, the theatre was saved, but it was taken down in 1783. The court room and entrance gateway of the old hall remain, the rest having been taken down in 1863-4.

Nothing is recorded about the Brewers' Company's Hall in Adde Street, except that it was rebuilt in 1666.

The original hall of the Carpenters' Company, in London Wall, was built in 1429, and was enlarged in 1664-5, escaped the Great Fire, and was repaired in 1670-1. The present hall was built in 1879. Samuel Angell designed the hall of the Clothworkers' Company, 41, Mincing Lane, which was built in 1856-9, and opened by Prince Albert in 1860. The hall erected in 1598 was partly destroyed by the Great Fire.

The Coach-makers and Coach-harness Makers' Company have their hall in Noble Street, Cheapside. It was built in 1870 in succession to a hall that had been rebuilt in 1811, on the site of the Scriveners' Hall, which had been purchased in 1703. The site was first occupied by the residence of Sir Nicholas Bacon, prior to his becoming the first Lord Keeper.

The Coopers' Company's Hall, No. 71, Basinghall Street, was built in 1868 from designs by George Barnes Williams, on part of the site of the hall which, dating from 1543, was destroyed in the Great Fire, and succeeded by Woodhouse's hall.

Mr. Chatfield Clarke's designs for the hall of the Cordwainers' Company, 7, Cannon Street, began to take shape in December, 1909, when the foundation stone was laid. It is the sixth hall built upon the same site, the first having been built in or about 1393.

Messrs. J. and J. Belcher built the hall of the Curriers' Company, 6, London Wall, the first stone of which was laid on December, 1874. The style is of Northern French Gothic type. There is an open timber roof, divided into panels,

with carved bosses at the intersections; and another fine internal feature is a large stone fireplace, about 16 ft. high, with the arms of the company in the centre of a carved canopy.

The Cutlers' Hall, in Warwick Lane, is noteworthy for its fine external frieze in terra-cotta showing the operations of the craft.

Thomas Cromwell, Earl of Essex, had a house and gardens in Throgmorton Street, and after his attainder the mansion and site were acquired, in 1541, from Henry VIII. The building was much damaged by the Great Fire, and re-edified next year from the designs of Jarman, the architect of the second Royal Exchange. W. Goodal repaired it, in 1775, after a fire in 1774; and after being twice refronted successively by Robert Adams and (in 1868-9) by Mr. Herbert Williams, it was altered in 1898-9 by Mr. T. G. Jackson, R.A.

The Dyers' Company's hall, 10, Dowgate Hill, was erected about 1776.

Fishmongers' Hall, London Bridge, was built from the designs of H. Roberts, 1831-5; the hall it succeeded having been built by Jarman after the Great Fire, which had destroyed the fifteenth-century hall in Thames Street.

The hall of the Girdlers' Company, 39, Basinghall Street, was built in 1681.

Philip Hardwick, R.A., designed the hall of the Goldsmiths' Company, in Foster Lane, Cheapside, which was opened in 1835. It succeeded a hall which, built in 1407, was damaged by the fire of 1666 and restored in 1669.

Wren designed, in 1668-70, the hall of the Haberdashers' Company, 31, Gresham Street, the Great Fire having destroyed a hall that was bequeathed to the company in 1478. In 1864 it was necessary to restore Wren's building after serious damage by fire.

The old hall of the Ironmongers' Company, in Fenchurch Street, existed in 1494, was rebuilt in 1587, escaped the Great Fire, and was demolished to make room for the present hall, which was built from the designs of T. Holden, and opened in 1750. The interior was remodelled in 1847.

A characteristic specimen of the enriched decoration employed after the Great Fire is found in the facade of the Mercers' Hall and Chapel, 87, Cheapside, which was erected from the designs of Mr. Jarman, in 1682, the preceding hall having been burnt in the Great Fire.

The largest of the halls of the City Companies is that of the Merchant Taylors, 30, Threadneedle Street. It was built, after the Great Fire, by the ubiquitous Jarman.

The Stationers' Company's hall off Ludgate Hill was mainly built immediately after the Great Fire. It was faced with Portland stone by Robert Mylne in 1805; and his grandson, Robert William Mylne, added, in 1887, the modern building at the north-east end. The old hall has a remarkable series of stained-glass windows.

Wren is supposed to have designed the hall of the Tallowchandlers, on Dowgate Hill, which was built in 1672, and restored in 1871 and 1890. He built the hall of the Vintners, in Upper Thames Street, and the first meeting was held in it in 1871. The ancient hall, known to have been in existence in 1352, was burnt in the Great Fire.

It is a great pity that many of these halls are so obscurely situated as to be quite unknown to the average Londoner; and even when he comes upon one in some cramped alley, he is often unable to

identify it, except perhaps as "the hall of some City company," but which company is not always clearly evident. It would be an obvious advantage if they were all plainly labelled. The interiors, often architecturally interesting, and many of them rich in objects of artistic and historical interest, ought to be more accessible than they are; but the obscurantist attitude of some of their custodians may be inferred from a note in the "City of London Year Book," in which it is stated that "official information has, in a few instances, been refused."

OUR PLATE.

The Apse of the Madeleine, Paris.

The Church of the Madeleine, situated on the Place of the same name, opposite the Rue Royale, was begun in 1761 or 1764, by Constant d'Ivry. He died in 1777, and Couture altered the designs, building the south-west facade as now seen. Under Napoleon, the work was continued in 1808, when Vignon, the architect, was required to modify the designs with a view to making the building a Temple of Glory in honour of the Grande Armée. After 1814 the work was again delayed; and in 1816 Vignon, in again taking up the work, reverted to the intention of producing a parish church on the model of a Greek temple. Most of the elevation is to be credited to him; but, on his death, the interior was arranged by Huvé. The Madeleine was not finished and consecrated until 1842. It forms a parallelogram 102 metres long by 43 metres wide, and stands on a basement 4 metres high from the ground. Around it there are 52 fluted columns, 15 metres high. The pediment of the main facade is filled with a bas-relief by Lemaire, representing the Last Judgment.

The apse, as shown in our Centre Plate, which is reproduced from a drawing by Mr. A. C. Conrade, is formed by a semi-circle of Ionic columns, supporting a painted semi-dome. The imposing sculptures of the altar represent the Magdalen with adoring angels.

OBITUARY.

Mr. Thomas Robert Macquoid, R.I.

The death has taken place at The Edge, Lucien Road, Tooting Common, S.W., of Mr. Thomas Robert Macquoid, R.I., at the age of 92. He was the husband of Mrs. Katharine Sarah Macquoid the novelist, and the father of Mr. Percy Macquoid the artist. Mr. T. R. Macquoid was a member of the Institute of Painters in Water Colours, and was a frequent exhibitor. In 1850 he published a volume of Examples of Architectural Art in Italy and Spain chiefly in the 13th and 16th centuries, which he compiled in collaboration with Mr. J. B. Waring.

Mr. John Hogan, M.I.C.E.

Mr. John Podevin Lemon Hogan, M.I.C.E., who has died at the age of 59, had risen to a high position in the Indian Public Works Department. Trained at the Thomason Engineering College, Roorkee, Mr. Hogan was appointed to the Department in 1873. After some years of employment on military works he was transferred to the railway branch in 1880. Later his services were lent to the Bombay, Baroda, and Central India Railway Company. He became a superintending engineer in 1899, and from 1901 to 1907 he was Junior Consulting Engineer to the Government of India for Railways.

MAGAZINES AND REVIEWS.

In putting together our monthly notes on some of the contents of magazines and reviews, we notice that the "Art Journal," with which we have usually commenced, has not appeared since February. We hope this does not mean that this art-serial, with such a long and creditable history behind it, has come to an end.

The "Burlington Magazine" contains an article by Signor Rivoira (who seems far better acquainted with British architectural monuments than most Continental archæologists) on the ancient tower and chapel of St. Regulus, or St. Rule, at St. Andrews, which has been to some degree a bone of contention with archæologists. Signor Rivoira, who goes into the question in an article which is a model of careful research and reasoning, considers that the tower and chapel show constructive unity, but that the western tower arch (now built up), though identical in size and proportion with the chancel arch, is the result of an alteration of the original building, it being inconceivable that, in those days, so large a portal should have been made at a western entrance to the tower. But the alteration must have been close on the original building, as the style of detail is similar in each arch. He regards the whole as the work of Bishop Robert after his consecration in 1124, the western arch being rendered necessary by an extension (now destroyed) of the original design. The argument agrees well with the evidence of the building, of which photographs are given. A date of two or three centuries earlier has been claimed for the building, but we think Signor Rivoira has proved his thesis, or at least rendered it highly probable. The same issue contains an illustrated article on the Byzantine enamels in Mr. Pierpont Morgan's collection, which are said by the author (Mr. Dalton) to afford the best means of studying this type of Byzantine work as it existed between the tenth and thirteenth centuries. The coloured illustrations of these small (sometimes minute) works are beautifully produced, and in themselves give a value to the issue in which they appear.

The most interesting article in the New York "Architectural Record" is one on "A Study of Romanesque in Spain," a country which we do not generally think of in connection with Romanesque architecture. The illustrations given serve, however, to show that Romanesque architecture in Spain showed much the same forms as in other parts of Europe; we find again the familiar flat strips of buttress ending abruptly under the eaves; and the doorway at San Millan, Segovia, and the interior of old Salamanca cathedral, might just as well have happened in early twelfth century France. The writer of the article, Mr. Stapley, thinks that American architects would do well to pay a little more attention to Romanesque; many an excellent American architect, he says, thinks Romanesque such an unused type that he need gave it no attention, "and the schools skip over it like a hurdle." Mr. Stapley is right; the study of Romanesque, besides its great interest in regard to historical development, is a lesson in the value of solid and massive design of truly masonic character. "Early American Churches" are interesting from looking so very English. A paper on "A Pioneer Architect," Mr. F. Lloyd Wright, shows in the illustrations that Mr. Wright has some ideas of his own in regard to the plan and design of house

architecture. Among other things, he has sensible roofs, either flat or on a very slight slope. The days of the exaggerated "picturesque" high-pitched roof ought to be considered over, and we are glad to find any architect thinking so.

The "Gazette des Beaux-Arts" commenced in its March issue a series of articles on "The Works of the Louvre under Henri IV.," by M. Louis Batiffol, said to be founded on new documents. The April number of the "Gazette" has not appeared yet (French periodicals being quite indifferent as to punctuality of publication); the March article goes to show that the whole scheme of connecting the Louvre and the Tuileries as one great architectural group was due to the architect Lescot. In England we have been recently told that Lescot was little more than a name in the matter, and that his influence over the Louvre design was of the smallest. M. Batiffol's article, and the information produced and the documents quoted in it, seem to prove the contrary.

The "Contemporary Review" contains an article by Lady Ritchie on "Alfred Stevens," giving some information about the artist which is of interest; especially the fact that he was engaged by Messrs. Hoole and Co. in designing a number of things for practical use, such as hot-air stoves, etc., for the 1851 exhibition, and that the firm carried away every medal at the exhibition. This is probably rather too sweeping a statement; but it is evident that Stevens had the true great artist's capacity for treating anything that he laid his hand on in an artistic spirit. A characteristic story is that while Stevens was teacher in a Government school of design, one of the students said to him: "I sketched in the ornaments, sir"; to which Stevens replied: "We do not sketch here, we draw"; a good lesson in a few words. Stevens resigned the appointment in two years, "disgusted," he said, "by the meddlesome supervision of ignorant Government clerks." One can understand that; Stevens was hardly a man to "suffer fools gladly." In his entire devotion to art, and apparent indifference to every other subject, he was a good deal like an artist of the Italian Renaissance come to life again.

In the "Century" Mr. Karl Bodmer publishes "Recollections of Millet," which are of considerable interest, but we notice that all the illustrations are taken from his peasant pictures, and there is not a word about his earlier works of imaginative subjects, which are in an artistic sense finer, though there is not the same simple earnestness about them. There were two Millets, and people seem to have forgotten the earlier one entirely, and somewhat exaggerated the later. Everything about Millet himself is interesting—even more so than his pictures.

In "Blackwood" the writer of "Musings without Method" has something to say, quite truly, as to the dignity and style of Vandyck's portraits, but indulges in a grumble, not quite justifiable, against modern English portraiture, as presenting "a bare literal record of unsightliness." The costume of the present day has not the splendour of the Vandyck costume; we cannot help that; but to say that there are no modern portraits which give us anything more than the details of costume—none that are fine works of art in themselves—is the dictum of a writer who is either prejudiced or who never sees the Royal Academy exhibitions, or goes through

them with his eyes shut. Bad and dull portraits there are produced every year, but every year there are good ones; they generally outnumber the bad. In fact, if there is one branch of art in which English is stronger to-day than in others, it is exactly portraiture.

In "Scribner" an article on "Cadenabbia" gives occasion for a number of charming sketches by Mr. Peixotto of picturesque bits of town and country in this district of Italy.

CORRESPONDENCE.

Cheap Cottages.

To the Editor of THE ARCHITECTS' AND BUILDERS' JOURNAL.

SIR,—I am inclined to think that "Clerk of Works," in your issue of April 10th, rather underestimates the capabilities of farm labourers, etc. In this district (Bedfordshire) men know how to do a good many other things besides farming, and several have, to my knowledge, built their own cottages—with a certain amount of help, of course. The result has been perfectly satisfactory.

Referring to the second point, I am afraid if a builder obtained skilled workers from away and paid them high wages in order to build cheap cottages his speculation would turn out somewhat unfortunate for himself. Such cottages are found on estates and so forth, where materials are to hand, and money no object, but not under ordinary circumstances.

If *builders* have to give up cottage building owing to increasing cost, it is obvious that something must be done to make it possible. Especially when the Planning Act is reducing the numbers. Besides, cottages are not meant to be built like mansions—they would lose their rustic appearance.

LICENTIATE R.I.B.A.

The Modern House.

To the Editor of THE ARCHITECTS' AND BUILDERS' JOURNAL.

SIR,—With reference to the notice, in your issue of the 3rd inst., on the paper I read entitled "The Modern House," I would like to point out that the "questions" were not asked by myself, but that I gleaned them from a publication issued by one of the Garden City Associations. I have not the document by me, but I have no doubt that all members of the profession received a copy of this circular.

I think you should have stated that I specifically disassociated myself from many of the views put forward; I am quite in agreement, however, with regard to the unsuitability of the large hall. I am acquainted with a great number of these, and do not know of one solitary case where this adjunct gives complete satisfaction in a small house. The objections to it are as follows:—

Lack of privacy; exposure to draughts; encroachment upon space which is better utilised in serviceable living-rooms, the improbability of comfortably warming same, and the impossibility of comfortably occupying a room into which any chance caller is liable to be incontinently admitted. All we require in this country for a hall is adequate space for a fireplace or a heating stove.

PERCIVAL M. FRASER.

[Extracts from Mr. Fraser's paper appear on p. 403.]

OPERATING THEATRES, BRADFORD.

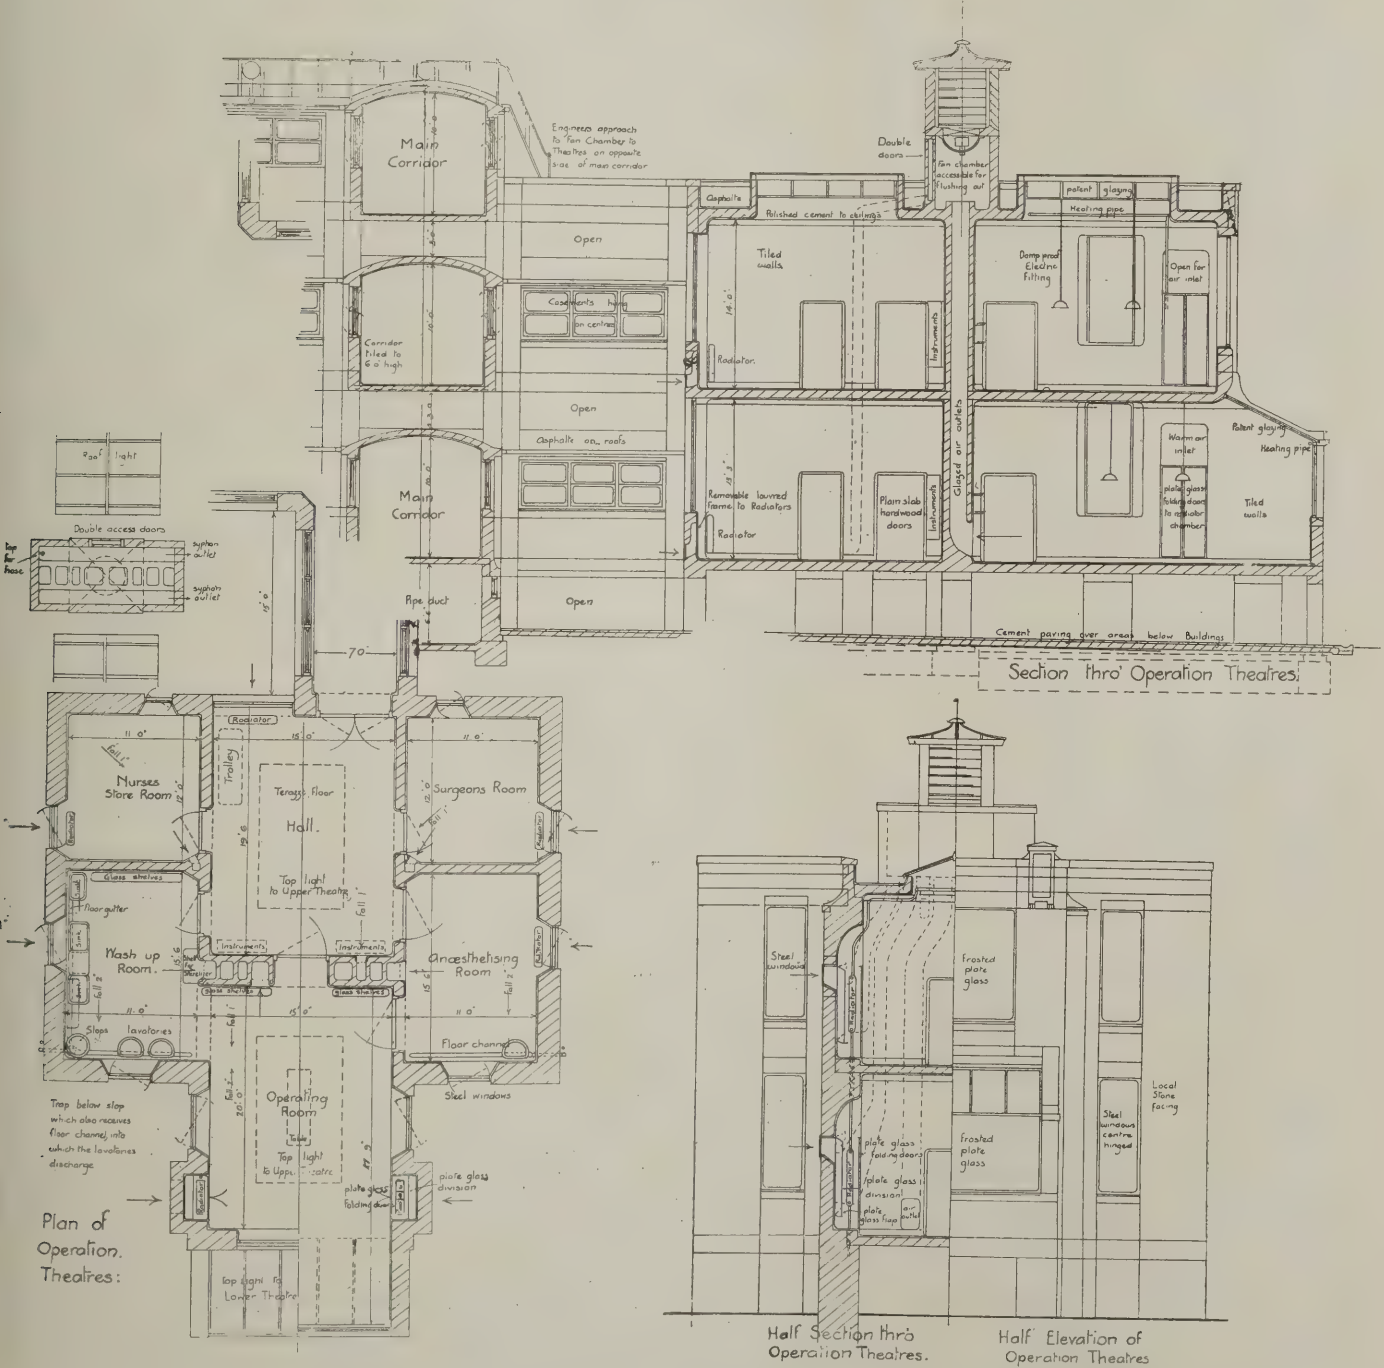

In this design provision is made for two operation rooms (the lower one being 416 sq. ft. in area, and the upper 300 sq. ft.), a sterilising and wash-up room 170 sq. ft. in area, anæsthetising room, surgeons' room, nurses' store-room, and a hall having a space near the entrance suitably arranged for the accommodation of trollies.

The theatre blocks are cut off from the main corridors of the infirmary by cross-ventilated lobbies. Heating and ventilation are provided by radiators fixed on brackets below the windows, except in the case of the operation rooms, which are arranged to be heated by coils fixed in recesses. Messrs. Everard, Son and Pick are the architects.

ROYAL SANITARY INSTITUTE CONGRESS.

The twenty-seventh Congress of the Royal Sanitary Institute is to be held at York from July 29th to August 3rd, during which period papers will be read on subjects relating to health and sanitary science. Those who desire to read papers at the Congress should forward their manuscript (which should not exceed 3,000 words) not later than June 29th, to the Secretary, Royal Sanitary Institute 90, Buckingham Palace Road, London, S.W.. No previously published paper can be accepted. The following sections will be represented at the Congress:— (a) Sanitary Science and Preventive Medicine; (b) Engineering and Architecture; (c) Domestic Hygiene; (d) Hygiene

of Infancy and Childhood; (e) Industrial Hygiene. Conferences of Municipal Representatives, Medical Officers of Health, Engineers and Surveyors to County and Sanitary Authorities, Veterinary Inspectors, and Sanitary Inspectors, have been arranged. In connection with the Congress an exhibition of apparatus and appliances relating to health and domestic use will be held. Tickets, price £1 rs. each (ladies' tickets, 7s. 6d., not including copies of Proceedings) may be obtained from the Guildhall, York, or from the offices of the Institute, of which the address is given above. Mr. E. White Wallis is the secretary. The Institute's policy of holding its meetings and exhibitions in a different part of the kingdom each year cannot be too highly commended.

DESIGN FOR OPERATING THEATRES, NEW ROYAL INFIRMARY, BRADFORD.
EVERARD, SON, AND PICK, ARCHITECTS.

PUBLIC OFFICES (SITES) BILL.

In the House of Commons last week, Mr. W. Benn moved the second reading of this Bill. He said its object was to acquire land for a new building for the Board of Trade and other offices. The site was bounded by the Embankment, the Horse Guards Avenue, Whitehall Gardens, and the grounds of Montagu House. The Board of Trade offices were situated on one part of the site, and the other part would be acquired first.

The new buildings for the Board of Trade would be erected on the portion which was to be acquired first. Those offices were urgently needed, for at present the Board of Trade was housed in 20 different buildings. The Bill also provided for the extension of the Patents Office in Holborn and for the acquisition of land as a safety girdle to protect the Records Office against fire. The cost would be paid in 60 half-yearly instalments.

Mr. W. Rutherford said land could be obtained within the same distance of the Houses of Parliament, but on the other side, at one-fifth of the cost which it was proposed to pay. Every day the representatives of the Treasury declared in answers to questions that they could not afford a few pounds for this or that, and yet when the public departments themselves were concerned they thought nothing of spending some hundreds of thousands in a perfectly unnecessary manner.

Mr. Whitehouse thought that before the second reading of the Bill was taken, hon. members should at least be afforded an opportunity of inspecting the plans. So far as he understood the Bill, the site taken on the Embankment included some garden space. He asked for an assurance that it was not proposed to build on any open space.

Lord A. Thynne said that, while he did not challenge the necessity for further office accommodation for the Board of Trade, he could not help seeing in this proposal another sign of the enormous growth that had taken place in bureaucracy in recent years. It would be perfectly possible to find a far cheaper site, and in his opinion it would be a great advantage to London if some of their great Government buildings could be placed south of the river. He also would like to have an assurance that the garden which was included within the limits of deviation would not be built upon. If it was, the architectural effect of the Embankment would be spoilt. The First Commissioner of Works had suggested that any antiquities found on the site should be handed over to the London Museum. He did not think that this was a satisfactory solution of the question, because the London Museum was partly a private undertaking, though it was accommodated in one of the Royal Palaces. He would prefer to see any archaeological or architectural object found on the site handed over to the London County Council and then lent on loan to the London Museum. Some interesting articles might be found, because the site was one of the principal ferries across the river in ancient Roman times. He asked the Government to give an undertaking that the London County Council and bodies like the City of Westminster would have a right to appear before the Select Committee in order that those who were principally interested in the maintenance of open spaces might have an ample opportunity to be heard.

Captain Murray said he was of opinion that the explanation offered on behalf of the first Commissioner of Works was hardly convincing why the Board of Trade Offices should be placed on the proposed site. The buildings would cover up a valuable open space, and he pressed for an assurance that the open space between the Board of Trade offices and the Embankment would not be covered up by the proposed buildings.

Mr. W. Benn, in reply to the criticisms and suggestions, pointed out that the new buildings were called for by the natural growth of the Administration which went on side by side with the growth of the population and the progress of the country. It was difficult for him to make any promise in respect of the antiquities that might be found and the giving of them to a third party, but the suggestions of the noble lord would be carefully considered in the event of antiquities being found. The First Commissioner of Works had been in consultation with the Clerk of the County Council on this subject. He pointed out also that the question of site had been considered by three committees, and the conclusion had been arrived at that this was the best, though not the cheapest, site for the buildings, taking into consideration the convenience of the public and the question of price. He could not say whether a site on the southern side of the river had been considered, but the whole subject had been carefully gone into. The estimate for the southern portion of the site for the new Whitehall buildings was £250,000, but the exact figure would have to be determined according to the clauses of the Bill. The plans referred to in the Bill had been deposited in the Private Bill Office and were open to the inspection of hon. members. Probably the First Commissioner would offer no objection to their being placed in the Tea Room. As to the gardens included in the site, he said that it was the intention of the First Commissioner, if the Bill passed, to invite the co-operation of a large committee representing all sections of the House to consider the best way of disposing of the site and the best kind of buildings suitable for it. But the fears expressed by the noble lord as to the fringe on the Embankment were not well founded. This, however, was a subject which could be better considered in Committee, and especially after the First Commissioner had heard the views of the persons who were to form the Committee.

Mr. Whitehouse asked whether he was to understand that it was not proposed to extend the building line to any portion of the existing garden.

Mr. W. Benn said that he did not think he ought to give a definite pledge in terms. It was not generally contemplated to utilise the gardens by building. The First Commissioner intended to invite the help of a committee who would decide the matter. The votes for the purpose would have to come before the House.

In reply to Mr. Fell, Mr. W. Benn said that the northern half of the site, which it was not proposed necessarily to take, would probably be worth about £200,000.

The Bill was read a second time.

Mr. Leonard Stokes, president of the Royal Institute of British Architects, has arrived at Winnipeg to examine the competitive plans for the new legislative buildings. The competition having been open to architects in any part of the British Empire, plans have been received from a number of Old Country architects.

URBAN AND RURAL HOUSING.

Mr. Beville Stanier's Rural Cottages Bill, published last week, seeks to set up a Rural Housing Department of the Local Government Board, to consist of three paid Commissioners, for the purpose of providing for the better housing of the working classes in rural areas. The Bill would empower the department to make inquiries into the demand for cottage accommodation and, where desirable, to co-operate with a committee of the County Council concerned in the preparation of a scheme. In the event of a committee failing to prepare or to carry out a scheme when directed to do so the Commissioners have power to do the work themselves.

Lord Strathie (former President of the Board of Agriculture), at last week's meeting of the Somerset County Council, gave a glowing account of the success that has attended the working of the Irish Labourers' Act, and moved that in the opinion of the council it was desirable to extend its provisions to English local authorities. Under the Act 23,000 cottages had been built, the money being advanced by the Government for 68½ years at 3½ per cent. interest. At the end of the 68½ years the houses would become the property of the rural districts, and the rents received would go to the relief of taxation. It was said that as a result of the Act the Irish peasantry were better housed than any other peasantry in Europe. The resolution was carried by 40 votes to 20.

The Local Government Board have withheld their consent to a scheme for the erection of fifty artisans' dwellings at Child's Hill, Hendon, on the ground that the proposals of the District Council are not satisfactory. The plans provided for cottages of five rooms to be let at 8s. 6d. per week. The Board state that in their opinion cottages of a more commodious type could be erected and let from 7s. to 7s. 6d. a week. The council, therefore, have amended the plans, and are about to advertise for new tenders.

The Local Government Board has sanctioned the borrowing by the Swansea Corporation of £6,550 and £10,167 for erection of artisans' dwellings on the Cwm Road and Trewyddia Common sites respectively. The Swansea Housing Committee has decided to acquire a freehold site on Town Hill from the Garden Suburb Freehold Company, Ltd., for £4,000. It is 30½ acres in extent. By this purchase the Corporation will be in possession of the whole of the top of Town Hill for development.

The members of Stafford Town Council, at their meeting last week, discussed at considerable length the recommendation of the Housing of the Working Classes Committee that twenty small dwellings to let at 4s. and 3s. 6d. a week inclusive of all rates should be erected by the Council on land in South Backwalls belonging to the Corporation. It was estimated that the total cost of the houses would be £3,200, and that the total annual charge would be £194. The recommendation was unanimously approved, and it was decided to make application to the Local Government Board for their sanction to the appropriation of the land and for the raising of the loan.

The inquiry as to a scheme for the erection of 267 cottages, at a cost of over £40,000, in the Newtownards Rural

NEWS ITEMS.

Death of Professor Pillet.

The death was announced last week of Professor Jules Pillet. Born in 1842, Jules Pillet entered the Ecole Polytechnique in 1861. He was appointed Professor at the Ecole des Beaux-Arts in 1880, and in 1885 Professor at the Conservatoire des Arts et Métiers. He also held a professorship at the Special School of Architecture and the post of honorary examiner of designs.

New Barracks at Aldershot.

Increased accommodation is to be provided for troops in three districts of the Aldershot command. New barracks are to be built for a company of the Army Service Corps at Bordon Camp; new shoeing forges and stores and new barracks are to be erected at Longmoor Camp, the headquarters of the Mounted Infantry; and additional storeroom accommodation is to be provided for the aircraft factory at Farnborough.

Town Planning Schemes for Sheffield and Newcastle.

It is understood that the Local Government Board have given authority for the preparation of four further town planning schemes under the Housing, Town Planning, etc., Act, 1909. Three schemes are authorised to be prepared by the Corporation of Sheffield, and one by the Corporation of Newcastle-upon-Tyne. In the case of Sheffield, the schemes are to apply to three areas within the city, situate at (1) Greystones and Bannerdale, (2) Sandygate, and (3) Firth Park, Wincobank, and Shire Green, and comprising about 1,100 acres. In the case of Newcastle-upon-Tyne, the scheme is to extend to an area of about fifty-three acres at Craghall Dene.

Canadian Government Offices in London.

It is stated that information is being obtained by representatives of the Canadian Government in London in regard to a number of sites suitable for the proposed new Canadian Government offices in London, but nothing will be done immediately in the matter beyond collating this information and forwarding it to the Government at Ottawa. Next month advantage will probably be taken of the presence of several Canadian Ministers in London to inspect all the available sites and make a final selection. With regard to Westminster Hospital, it is understood that the Governors would be prepared to consider favourably an adequate offer for the land on which it stands in Broad Sanctuary; but if the £200,000 voted by the Dominion Parliament is to cover the cost of both land and buildings for the new offices, the Westminster Hospital site would be too expensive; the Westminster Hospital site being unofficially valued at between £250,000 and £300,000.

Light on Hittite Architecture.

Interesting details of the work done by the German expedition in Central Mesopotamia under Baron Oppenheim have reached Berlin. For some time the expedition has been at work excavating at Tel Halef, the site of the ancient capital of the Hittite Monarchy, and have succeeded in unearthing a series of magnificent works dating back to about the fourteenth century before the Christian Era. The almost entire and gigantic

foundations of a royal palace have been laid bare. Baron Oppenheim has established the fact that this structure rose on an elevated terrace, rectangular in shape. All four walls of the palace contribute a splendid series of stone reliefs, with most remarkable sculptured groups and single figures in an almost perfect state of preservation. Of these "plates" over 170 have been unearthed. Great stress is laid on the discovery of the palace gate. Two colossal basaltic figures of animals have been discovered, which doubtless guarded the approach to the gate, and strongly resemble the similar beasts on Babylonian monuments.

L.C.C. New Schools.

At the last meeting of the London County Council, before the adjournment for the Easter recess, a report was received from the Education Committee stating that work is proceeding in connection with the erection of two new central schools and four new secondary schools, and the enlargement of three elementary schools. The total additional accommodation thus provided will amount to 3,535 places, at an estimated cost of £145,326. Five schools are being structurally improved by the provision of halls, etc., at a cost of £63,100, and one school is being rebuilt at a cost of £18,696. On the opening of the new training college which is in course of erection at Highgate, the whole of the premises at Finlay Street will be used for elementary school purposes, representing an increase of about 700 school places.

Indian Bridge Contract Goes to America.

The India Office has just awarded a contract for the whole of the steelwork required in connection with a new bridge to carry the Oudh and Rohilkund State Railway over the River Jumna at Hamirpur Station, near Allahabad, to the Phoenix Bridge Company, of Phoenixville, U.S.A. This new bridge will have twelve spans, each 250 ft. in length, and of 315 tons weight. It is by far the largest bridge contract for any of the Indian State railways which has been placed in America during the last 25 years, and in response to invitations, tenders for the execution of the work were submitted by a dozen of the leading bridge-building firms in Great Britain and North America. There was a difference of 26½ per cent. in the amount of the Phoenix Bridge Company's tender and the lowest British tender.

Paris and the Housing Problem.

At the moment Paris is taking up the question of workmen's dwellings very seriously, and the Municipal Council is considering the proposal of a loan of eight million pounds for the purpose. The real problem, however, is not the raising of the necessary capital, but the discovery of the appropriate designers. The efficiency of the municipal architects for such strictly utilitarian constructions is being widely questioned in Paris. Even the most strenuous supporter of the new scheme, M. Frédéric Brunet, is very dubious about the advisability of employing the official architects, and advises a system of open competition on the most liberal lines. This consequence of the new housing scheme is illuminating. It shows clearly, an editorial writer in the "Westminster Gazette" assumes, that the elaborate system of municipalisation and nationalisation of the arts and crafts which

PORTINSCALE BRIDGE.

A public inquiry was held at Keswick last week by the Cumberland County Council to hear evidence for and against the proposal of the Council to build a new bridge at Portinscale in place of the ancient one, which has been for some years closed to heavy traffic. There was a large attendance from all parts of Cumberland. Mr. Howard, of Greystoke Castle, Chairman of the County Council, presided.

The case for the supporters of the present bridge was stated by Mr. Frank Marshall and Sir Robert Hunter, Chairman of the National Trust. They contended that the best local feeling was entirely antagonistic to a new bridge.

Canon Rawnsley called attention to the fact that in one week he received 60 letters in answer to a letter in "The Times" from people who knew Portinscale Bridge, all of them condemning the proposed bridge. It was plain that the bridge was one of the attractions of the neighbourhood, and that it was valued by the people of Cumberland was shown in many ways. It was desirable on the ground of economy to spend no more money than was inevitable at Portinscale, as there were much worse places in the district. To place a new bridge 60 yards away and keep the old bridge standing would be an absurdity. The view down the river would be entirely spoiled, and one of the most beautiful reaches would be entirely hidden from the new bridge. The bridge had been thought so interesting that it had been scheduled for preservation under the Ancient Monuments Act.

Mr. William Shires, timber merchant, Braithwaite, contended that the present structure was dangerous, while this characteristic was not relieved by any historic or specially artistic merit.

The Chairman asked Mr. Marshall if all the sentiment would not have disappeared after alterations, seeing that it would be practically a new bridge.

Mr. Marshall said he did not accept that interpretation, except as to the recesses.

The Chairman asked if it was not the site rather than the bridge that they were so keen about.

Mr. Marshall: The making of recesses would not materially change the character of the bridge. You evidently do not object to altering the bridge.—I do not object to altering it in that detail because it is in character.

The Chairman said that reducing the gradients and raising the parapets would alter the characteristics.

Mr. Marshall: If the hump is characteristic, I am quite prepared to give the hump away.

The Chairman said the committee would report to the Council, and it is understood that the subject will be discussed at the May meeting.

has during the last generation been so marked a feature of French administration, has ended in a really sterile academism in the case of architecture at least, which has resulted in a serious waste of public money over the cost of material, and also in the construction of edifices which are from the utilitarian point of view ridiculous failures. Paris, our contemporary concludes, is becoming a little tired of architectural bombast.

London Street Paving.

In 1903 at a conference of representatives of the Metropolitan Borough Councils a committee was appointed to consider the general question of materials and means of paving the streets of London. This committee, of which Mr. A. C. Morton, M.P., is chairman, has now published its ninth annual report. From this it appears that the principal kind of paving laid down last year in the main roads was creosoted soft wood, generally laid close-jointed and "grouted" with pitch. Some boroughs favour a foundation of Portland cement concrete 9 in. thick, while others appear to consider a 6 in. foundation sufficient, even in main thoroughfares. Complaint is made that motor omnibus traffic is detrimental to macadam-paved roads, but, in the absence of any statements to the contrary, it would appear that such traffic is not particularly detrimental to the surface of wood-paved thoroughfares, provided that an extra thickness of concrete foundation is laid. The most striking feature of this year's return is the saving which has taken place owing to the tar-spraying of macadam roads in the cost of scavenging, watering, and maintenance. For instance, in Wandsworth, the expense of these services before tar-spraying four years ago was £96,035 per annum. It has now been reduced to £62,760, whereas the cost of four years' tar-spraying was £6,731.

BREVITIES.

Salford Town Council have decided to erect, in South Backwalls, twenty working-class dwellings, to cost £165 each, and to be let at 3s. 6d. and 4s. a week.

Acton Council has approved of a scheme by the Goldsmiths' Company for the laying out of its estates at East Acton and Acton Vale on town-planning lines.

Halifax Town Council have decided to apply for authority to prepare a town-planning scheme in respect to 880 acres in the Overden district, and 756 acres in the Warley district.

A site for a proposed new temporary school near St. James's Lane, Muswell Hill, is to be purchased for £1,050 by the Hornsey Education Committee.

It is proposed to erect public baths and a public hall on a site fronting Harrow Road, Paddington. The site will cost £18,500.

The Road Board has renewed its offer to contribute, subject to the approval of the Treasury, £875,000 towards the construction of a new western approach to London, of which the cost is estimated at £1,750,000.

In a volume just issued the Associated Newspapers, Ltd., give reproductions of the hundred best designs received in the competition for their £100 prize in connection with the Ideal Home Exhibition now being held at Olympia.

Sheringham Urban Council's new offices, which have just been completed, have been built by Messrs. Blyth and Son, con-

tractors, from designs by Messrs. Stanley, Simons and Co., architects. The contract price was £1,285.

Satisfactory progress with the construction of Liverpool Cathedral was reported at last week's meeting of the Executive Committee. The walls of the choir have now reached a height of 119 ft. 6 in., and those of the chapter-house 49 ft.

London County Council, after an all-night sitting last week, adopted a scheme for the Council to lease cottages to tenants, so that working-men might acquire the leasehold on easy terms. The scheme, which was strongly opposed, will require Parliamentary sanction.

Mr. F. Howorth, architect, has been appointed architect for the building of a new workhouse at Ribchester. The names of two architects were submitted to the vote at a meeting of the Preston Board of Guardians, Mr. Howorth obtaining 26 votes against 23.

An international and universal exhibition is to be held at Ghent from April 25th to October 25th, 1913. It will cover more than 350 acres, and includes twenty-seven buildings, one of which, housing the Ghent Flower Show, will be considerably larger than the Crystal Palace.

A Dutch village, with dwellings, windmills, canals, tulip-fields, and industries, forms a striking feature of the Ideal Home Exhibition which was opened at Olympia on Friday last.

THE STATUTORY REGISTRATION OF ARCHITECTS.

The President of the Society of Architects, Mr. George E. Bond, J.P., has issued an important statement from which we make the following extracts referring to the Society's position with reference to the negotiations with the Royal Institute:—

As a result of negotiations between representatives of the Councils of the Royal Institute and of the Society, extending over fifteen months, certain proposals for the fusion of the Society with the Royal Institute and the promotion of a Registration Bill were agreed to, but on the scheme being submitted to a general meeting of the members of the Royal Institute on January 8th last, the proposals were referred back to the Council of that body for further consideration.

The members of the Society have consequently not yet been called upon to express their opinion on the above proposals by voting, but they have severely and adversely criticised them by correspondence, more particularly with regard to the question and terms of the fusion of the two bodies. The opponents of the scheme on both sides claim that too much was to be conceded for the little to be obtained in return.

The position of the Royal Institute is that it is pledged to registration, and its Council have appointed a committee to consider the matter in view of the situation created by the reference back to them of the proposals above mentioned.

The position of the Society is exactly what it was before, that is to say, it is pledged, as always, to registration, but not to any course of action therein with the Royal Institute, and the Council of the Society will not initiate further steps in regard to the fusion of the Society

with the Royal Institute, though they will be prepared favourably to consider and discuss any reasonable proposition in regard to the subject which may be submitted to them by the Council of the Royal Institute.

In regard to registration, a new situation has arisen. The Society of Architects has been the pioneer in this movement for considerably over a quarter of a century, and when the Council of the Royal Institute adopted a registration policy, this enabled negotiations to be opened with them with a view to the promotion of a joint Bill.

In the early stages of the discussion it became apparent that with regard to one of the main points of the proposed Bill, my colleagues and I, as representing an independent architectural body, could not possibly agree with the view put forward by the representatives of the Royal Institute, and as they were equally determined not to accept ours, the question of amalgamation was suggested to us as a way out of the difficulty: for both parties recognised, as all thoughtful persons must, that in the present congested state of public business in Parliament a contentious Bill would not have the least chance of reaching a second reading; and that neither party could hope, under these conditions, to pass a Bill through Parliament unless there was unity of action.

As, however, the Council of the Society of Architects have laid down, in the proposals for the fusion of the two bodies, the minimum which they can recommend their members to accept, and as these proposals have been severely criticised by the members concerned, it would seem unlikely that further progress can be made in this direction, but there remains the alternative of continuing the negotiations with regard to a joint Registration Bill; and we are prepared and indeed desirous of continuing them, hoping thereby to establish that unity of action which is essential in that case to success.

The opinion has been very freely expressed by many influential members of both bodies that in order to secure the passage of a Bill which will protect the interests of all practising members of the profession, and not merely those belonging to one institution, it is an essential condition that the Society of Architects shall continue its existence as a powerful independent body.

I may here state, that at the time the negotiations with the Royal Institute were first opened, the Council of the Society had formulated a certain course of action in regard to the introduction of the Society's Registration Bill into Parliament, and the machinery which then existed is still available, and should it eventually be found impossible to make progress in any other way, that machinery will be set in motion. In other words, we are prepared, if necessary, to resume at any moment that active independent propaganda hitherto so successfully pursued, but which we temporarily suspended in order to consider another means of attaining the same end.

Having made clear the present position as between the two bodies, and the policy of the Council of the Society in regard to the registration question, I would now call attention to the fact that the work and activities of the Society in other directions are being carried on exactly as before, without reference to any matters pending between the Councils of the Society and of the Royal Institute.

The London Society and London Improvement.

HAT has become of "the London Society?" We chronicled its opening meeting some months ago, when its formation was resolved upon amidst a good deal of enthusiasm; but we hear nothing more of it since, and we observe that the question has been raised in the general Press, in one quarter at all

events, as to what this society is going to do, and how far its membership has progressed and prospered. One would certainly like to hear some further sign of life from it. For a society of that kind to produce a definite effect either upon opinion or upon action in regard to London improvements, it is essential that it should be a numerous body. People in London are in general so slow to take up any new ideas about public improvements, so difficult to arouse to any enterprise or enthusiasm in regard to such subjects, that it becomes of consequence to draw as many of them as possible into the net of a society pledged to improvements. It was, we suppose, with that idea that the subscription was fixed at what was considered the low figure of one guinea. But there were criticisms heard in the room, at the time of the meeting, that this was too high, as a matter of policy, for the best purposes of such a society. Would not a half-guinea subscription have been a wiser enactment? As it is very well pointed out in the "Graphic," if one person in every thousand of the London population joined the society, it would be the largest society in London. We doubt if one person in a thousand can be got to pay a guinea subscription, but it might be possible to get that number, or even a larger contingent, with a half-guinea subscription. There must surely be one in a thousand people in London who care about its improvement; let the society announce a half-guinea subscription and invite them to come in; so that every one who is interested in the subject may realise that there is a machinery provided, or in course of provision, to initiate and assist schemes of improvement.

After that move for popularising the society and enlarging its borders has been carried through, we should like to hear something as to what is to be done; what schemes the society proposes to promote. We may name here some which might and ought to be considered.

The first thing to be done in London is to obtain a general official and public recognition of the principle that the erection of any important new building is not merely a question of architectural design, but of architectural placing. That is the point in which, in London, we are so much behind the two most important capitals on the Continent. Over and over again we have lost or spoiled an opportunity by erecting a building in the wrong place and laying out a street on the wrong lines, or with no sense of lines at all. We want to see established something like a popular opinion on that subject, a general recognition of its importance; and that is one reason for desiring the most extended membership of The London Society. With the general support of one in a thousand (or more) of the population, the society would form in itself a nucleus of enlightened

public opinion, sufficiently numerous to exercise a real influence on the still wider public opinion outside of its ranks. If such a society, in such numbers, had been in active existence two or three years ago, it may be questioned whether the unsatisfactory proposals for St. Paul's Bridge would ever have been put forward at all; it would have been known that there would be a considerable body of Londoners who would not have been satisfied with them, and who would have been too numerous and influential to be overlooked. If the society, in such large numerical force as we suggest, was in active existence now, it was probable that we should not have had the new demonstration just made against the completion of Regent's Quadrant on the new design, or the almost scandalous suggestion that (to please the shopkeepers) it should be pulled down again.

Perhaps one of the first things that we ought to look to in the way of London improvements is the condition of the south bank of the Thames, between Westminster and Blackfriars Bridges. More than half a century ago we made the great improvement which changed the north bank from a muddy shore, with a heterogeneous collection of buildings on it, into a grand roadway and a masonry river-wall. The building of the London County Hall has rendered essential the formation of a similar roadway and quay in front of it. Is it to stop there? Surely not. The commencement of a Thames embankment there should be continued at least as far as Blackfriars Bridge, where the northern embankment now ends. That would be one of the greatest London improvements waiting to be accomplished; as a duplicate of the northern embankment it would give a splendid unity to the scheme.

Another work which needs to be taken in hand is the proper architectural treatment and laying out of the open space at Hyde Park Corner. When the arch was moved from the position parallel with Apsley House, which it formerly occupied (a fact which is almost forgotten now), it made no doubt an axial termination to Constitution Hill, but in every other respect the scheme was carried out without any architectural sense whatever. The open space is cut up into shapeless triangles of land, and the arch on its western face fronts nothing, and is axial with nothing. It would be quite possible, even now, to lay out the space in an architectural manner. The Wellington monument would have to be shifted to do this; it would have to be manipulated so as to come into an axial scheme; but there would be no impossibility in this. The monument itself, it must be admitted, is a very poor thing, not artistically valuable either in an architectural or a sculptural sense, and as far as art is concerned it might be thought that it were better obliterated altogether; but that would hardly, in other senses, be right. A monument to a great man, once put up, is a thing to be treated with respect, apart from any question of its artistic value.

The next thing we would suggest is that a new façade ought to be erected to Buckingham Palace. We have always thought, and one of the competitors thought also, that a new façade to the Palace ought to have been an integral part of the Queen Victoria Memorial scheme. As it stands, the Palace façade, poor and commonplace as it is, is an anti-climax to the great road leading up to it, and the

large and rather pretentious memorial standing in front of it. As things are, of course, the new façade could no longer be thought of as coming into the provision of funds (already we suppose exhausted) for the Queen Victoria Memorial scheme. It would have to be regarded as a separate outlay. And surely it would be worth while, as a matter of national dignity, to spend public money in giving an adequate façade to the principal royal palace in the capital, the shortcoming of which has become all the more evident since the carrying out of the Memorial Road. And there is a further suggestion to be made in connection with this idea. Our official architectural establishment has made such a sad muddle with the surroundings of the Marble Arch that the unfortunate erection looks ridiculous in its present position. The Marble Arch was originally erected in front of old Buckingham House, on the site of which Buckingham Palace was subsequently built; it formed the state entrance to the forecourt there, axial with the Mall. Well, then, pull down the Marble Arch once again, and transport it to its old position, as the state entrance to the forecourt of the present palace. It is not a very remarkable architectural monument; but it has a history; it would be a pity to destroy it; it has no purpose or fitness where it is, but as a gateway to the palace forecourt it would be in a position in which it would have some meaning, besides which there would be a certain historical fitness in restoring it to its original purpose on nearly its original site.

Another important subject is the improvement of Piccadilly Circus (which has practically ceased to be a circus) into what would become in that case Piccadilly Place. Mr. Norman Shaw made some years ago a fine plan for this which would involve extending the open space for a considerable distance eastwards; rebuilding the block which is now Swan and Edgar's premises in a style to harmonise with the new buildings in the Quadrant, and making an effective east elevation towards the new Place; and removing the commonplace architecture of the London Pavilion to make way for something more worthy of the site. This plan was published some time ago, and excited a good deal of enthusiasm among those who saw it; but the project seems to have gone to sleep ever since, and nothing more has been heard of it. It is surely time that the possibility of carrying it out were taken into serious consideration. And in connection with this comes the necessity of securing the eventual completion of both sides of the Quadrant in accordance with the monumental design of the part now erected. That is a thing that must inevitably be done, in despite of the outcry of the shopkeepers, unless one of our most remarkable schemes for the architectural improvement of London is to look ridiculous. It is unfortunate that the new buildings are higher than the old ones, for the latter were just the right proportionate height for the width of the street, and with the new buildings it will look too narrow; but that was not the fault of the architect of the new portion; he did all he could to keep the buildings down. It is this modern desire to get still more and more rental out of every square yard of ground which is leading everywhere to the erection of buildings too high for the width of the streets, which was calculated for buildings of less height. If this goes on, it will end in transforming our best streets into gigantic alleys, narrow passages between lofty buildings; and nothing spoils the look of a city more. The fact is, that where a demand is conceded for greatly increased height in the building line, in new premises, it ought to be accompanied by a condition that the building should be set proportionately back from the original street line. If this were done in every case, if the height were increased all along the street we should eventually have a wider street, suitable to the increased height of the buildings. It is a point which the London County Council ought seriously to consider, for it not only concerns architectural appearance, but health. To go on building higher and higher on the same area of ground means eventually a complete overcrowding of the city with buildings which have not sufficient open space around them.

Then there is the proposal, which has been much discussed, of taking Charing Cross Station to the other side of

the river, and replacing the railway viaduct by a new and wide bridge for general traffic. This would be an immense public improvement, both in regard to convenience and appearance; the railway viaduct is a very ugly structure in itself, and the stoppage of all cross-river road traffic at this important point, and sending it round by two long detours over Waterloo or Westminster Bridge, is an absurdity; one wonders that there has not been a public outcry in regard to it long ago. But in London, we are far too much accustomed to act on the maxim that "whatever is, is right."

This reminds one of the importance of the whole subject of bridges over the Thames, over which those who care about the architectural improvement of London are kept in a state of continual anxiety every time a new bridge is talked about. Bridges are supposed to be a class of structure with which engineers only are concerned; and as engineers for the most part care nothing about the appearance of a bridge, but only about structure and gradients, the first thing we generally hear about a new bridge is that "the engineer has prepared a design which is quite satisfactory to the committee," and so on. Then comes the difficulty of ousting the engineer from the sole charge of the erection, and of persuading the official bodies and the public that in erecting so important a structure as a new bridge in a great city there is something else to be thought of besides gradients, headway, and span. All this ought to be stopped once for all, and the settled view accepted that a city bridge is of architectural as well as of practical importance, and ought to be advised upon and designed accordingly.

These are a few among the great London improvements which a body like the London Society, if it carries out the programme sketched for it at the opening meeting, ought to be able to do much to assist and promote; and so we ask again—what has become of the London Society, started at an enthusiastic meeting, and when are we going to hear more of its constitution and its undertakings?

The Society of Painters in Water Colours.

THE present is hardly one of the best of the Society's exhibitions, but there is this special interest about it, that some of the most gifted members of the Society have started on rather new lines of style, or of subject. Miss Fortescue-Brickdale is one of these. Instead of subjects with figures on a large scale, she shows us this year a terrace in some ideal garden, backed by rich masses of foliage, with little highly finished figures engaged in or looking on at a game of archery in which the shooter for the moment is directed by a winged figure of Cupid. It is a small work in a grand style, looking like a large picture seen through a diminishing glass, and in its peculiar way is one of the best things the artist has done. Mr. Crockett, whom we have known mainly as a painter of pretty village maidens in breezy landscapes, has served the visitors with a conundrum in the shape of a large allegorical drawing entitled "Transition," a very clever composition to the meaning of which no clue is given, and one is certainly needed. One of his pretty rustic figures, with her usual charm, is seen in the scene called "A Windy Corner." Mr. Walter West, besides sending one of his usual highly finished interiors with figures, appears also as the painter of a fine and effective landscape, "Moonrise in Italy." It is always gratifying to find artists of exceptional talent trying a new class of subject, and declining to move in one accepted groove.

Mr. Hughes, who seldom repeats himself, has two remarkable works; "Blondel's Quest," the troubadour singing under a castle wall the song which was to unearth Richard Cœur de Lion—a work with a very original colour scheme; and "Night with her Train of Stars," a heavily robed, crowned figure floating through the night, followed by her train of stars, infant figures each with a star on its forehead; one of the most elaborate and successful works of this class which he has produced. Among other figure

subjects of importance is Mr. Anning Bell's procession of the women bearing spices to the tomb of Christ, which only just misses of being solemn and pathetic from the faces looking rather too much like portraits of individual personages; as Burne-Jones said, it is better to be a little more abstract in portraying ideal scenes. Mrs. Laura Knight is at her best in "The Flight," where two girls in a bright landscape watch a flight of birds. There are too few of such purely artistic conceptions in the exhibition; too many of such pictures as "The Short Cut Down the Cliff," and "Congratulations," and so on; commonplace incidents of life cleverly painted in a commonplace spirit. We see pictures of this class every year, and wonder why they are painted and who is supposed to care for them; but we presume they hit what is called "popular taste."

Among the landscapes Mr. Philip is as grand as usual with his "Storm" in the Isle of Skye, and Mr. Paterson also makes a grand effect in "The Castle: Morning Mist," in which a mediæval castle rises out of a belt of fog; it looks rather like a "made" effect; still, this is the poetry of landscape, unlike the mere prose of Mr. Gregory's carefully elaborated scenes. Mr. Eyre Walker seems to be experimenting in a new method of treating the colour of landscape, and the results are less fascinating than usual in his work, but perhaps something will come of it. Mr. North gives us one of his best visions of a landscape steeped in a "light that never was on sea or land"; beautiful, but hardly nature; while Mr. Robert Little treats nature so as to extract an artistic meaning out of natural effect; "Pittenweem Harbour, Evening" is, in a quiet way, one of the best things he has done. Among other noteworthy landscapes are Mr. Albert Goodwin's "In the South Seas," with its remarkable study of tropical vegetation in the foreground, and Mr. Allan's perfect bit of open-air effect in a picture of "Summer Morning at Brora"; and Mr. Dollman, whom one generally regards as a figure painter, has achieved in his "Sussex," one of the most perfect small landscapes in the room—the very spirit of Sussex scenery.

Architectural subjects are numerous and mostly good; Mr. Reginald Barratt is, as usual, admirable in his combination of architectural truth of detail with pictorial effect; we know of no other artist of the day who can draw and paint architecture with such force and realism and yet never give us the impression that this is merely "an architectural drawing": differing in this respect from Mr. Rooke, whose architectural drawings are most careful and conscientious, but are not in the true sense pictures. Mr. Paterson, on the other hand, hardly emphasises the texture and details of buildings sufficiently, when he takes them as subjects, but he has made an effective picture out of a mediæval castle, "En Touraine," with its perspective of round towers and their conical roofs. Among drawings which come under none of the above-mentioned categories we must not omit a word for Miss Macallan Swan's still-life study of "Wall-flowers" in a jar; a splendid piece of colour.

The Housing Problem in London.

MR. RAYMOND UNWIN writes to congratulate the "Times" on the insight shown in a recent article on this subject, in perceiving that the real escape from the difficulty of providing houses for the working classes lies in the adoption of the principle of providing for all classes of houses on one area or in one district, instead of keeping upper, middle, and lower-class dwellings as separate speculations. This is, of course, the principle on which the Hampstead Garden Suburb was planned, with which Mr. Unwin was a good deal concerned. It is argued that the middle-class house is the most profitable as a building speculation, and will therefore always be preferred by the speculating builder to an outlay on working-class dwellings; therefore let us encourage the laying out of building estates for the joint production of both classes of dwellings. We fear that both the "Times" and Mr. Unwin are consciously or unconsciously shutting their eyes to facts. Whatever may be thought as to the principle, the fact remains that

people who live in houses of a certain class and standard do not want to have their dwellings contiguous to or mingled with others of a lower class and standard; and the immediate result of making the attempt would almost certainly be to lower the rental value of the better class of houses; so that the scheme would, financially speaking, cut its own throat. It is all very well to say that it is so much more beautiful for rich and poor to live together in the same or in contiguous streets or squares, and not to shun each other; it may be so in theory, but in practice it will be found that neither class desires the amalgamation, and it is no use legislating for it. You may do this: you may, in the case of a very large new building estate, sell or finance it on condition that a certain proportion of the land is to be utilised for working-class dwellings, where there is room to divide up the estate for different classes of property; but it is no use endeavouring to mingle them; neither class likes it—the poor, we believe, even less than the rich. But there is one good suggestion made by Mr. Unwin, that the limitation of the number of houses to an acre should be modified with reference to the size and cost of the houses. Otherwise the probability is that each plot will be made of sufficient size to accommodate a fairly large house, which house, in the case of the working class, will come to be occupied by two families. Logically, no doubt, the limitation as to the number of houses per acre should bear a relation to the obligation as to the size and rental of the houses. So far, building legislation may be framed so as to encourage the building of working-class dwellings; but to propose to mingle them with higher class dwellings is only attempting to ignore human nature and the habits and traditions of modern life.

The Question of Employment Cards.

IT appears, from a report of a recent meeting of the London Society of Master Decorators, that a proposal to issue employment cards, which the workmen could carry about with them, and on which would be entered the particulars of their employment, rates of wages, date of discharge, etc., is under consideration. The advantage to the employer is obvious. It would enable him to form some opinion of the qualifications of men applying for work. It seems to be thought that the men would raise no objection to this system, since it would give preference to competent workmen; and it has been resolved to ask the unions "whether they were willing to co-operate," and if so, whether they would agree to pay for the cards. We have, of course, no desire to interfere with the domestic economy of the Society; but since the proposal has been made public, and is therefore a fair subject for comment, we should like to do them the service of saving them, if possible, from any further trouble in the matter. In the report of their proceedings there is no evidence that they are aware of the extreme bitterness of the opposition with which similar proposals have been met. It may therefore be useful to recall that years ago the bricklayers repudiated the practice in a veritable passion of protestation; and in certain callings outside the building industry the abuse known as "chair-marking," to which a similar system was found to lend itself, led to violent turmoil and to considerable litigation. Unscrupulous employers devised means of indicating on the tickets—by initialling them in a peculiar way, or by placing dates or other marks in an agreed position—their distrust or adverse opinion of the holders, who, on becoming aware of the trick, naturally refused to bear about with them when seeking for work the tacit condemnation of their own characters, and so the system speedily drove them into open rebellion. Possibly we are living in more ingenuous and more tractable times, in which all employers are beyond suspicion, and all workmen are trustful and docile. We are quite sure that the proposition has been put forward in entire good faith and with the best possible intentions; but we greatly doubt the wisdom of persevering with it, and tender this advice in all friendliness, in the sincere hope that it may prevent possible friction with the unions.

Wren's Use of Portland Stone.

A WRITER in the "Pall Mall Gazette," Mr. W. Johnson, F.G.S., makes some remarks on Wren's use of Portland stone which are worth repeating.

It is safe to assert, he says, that of all limestones which have been employed in our great public buildings, Portland stone meets the eye most frequently. It was made popular by Inigo Jones and Sir Christopher Wren, though its occasional use can be traced back as far as 1623. Jones had actually restored a portion of old St. Paul's with Portland stone, and when Wren, after the fire, commenced the new cathedral, he cast around for a suitable building stone. "All the most eminent masons of England," he says, "were of opinion that stone of the largest scantlings was to be obtained there [at Portland] or nowhere." So to Portland Wren travelled. His inspection pleased him, and the Grove Quarry, situated near the East Cliff, was opened. This particular quarry has now long been abandoned, because the stone, being of a somewhat harder nature than usual, was a little more expensive to work.

Portland limestone, to give it the more explicit name, though typically developed in the peninsula, is also obtained elsewhere, as in the Isle of Purbeck and the Vale of Wardour. The rock occurs in a series of beds belonging to what geologists call the Jurassic period; that is, to an era far anterior to the deposition of the chalk downs of the Home Counties. A close examination of an average specimen of Portland stone will show that the rock is oolitic—that is, it possesses an oviform structure resembling a little the roe of a fish in appearance. Generally, the constituent particles are so fine that their rounded shape might be overlooked, and though the spherules are of larger size in certain strata, rarely do

they approach the coarse-grained but softer oolites of Bath and the Cotswolds, or the freestones of Northampton and Lincoln. In those coming from a group of strata, and not from a single layer, one would naturally expect considerable differences in the quality and texture of the material. And this Wren discovered to be the case.

Among the buildings in which Portland stone has been used are Somerset House and the British Museum. One particular quarry supplied the material for these, while from another was obtained the stone for the walls of the Goldsmiths' Hall and the Reform Club. Still another quarry was utilised for the Foreign Office and the Horse Guards.

The important question is: How far is Portland stone affected by the smoke-laden atmosphere of London, with its comparatively large percentage of acid constituents? The answer, in brief, depends upon the quality of the stone selected. Samples in which the tiny egg-shaped granules are bound together by a partially crystalline carbonate of lime stand the wear and tear well, but where the cementing matter is impure and more friable the mass tends to crumble away.

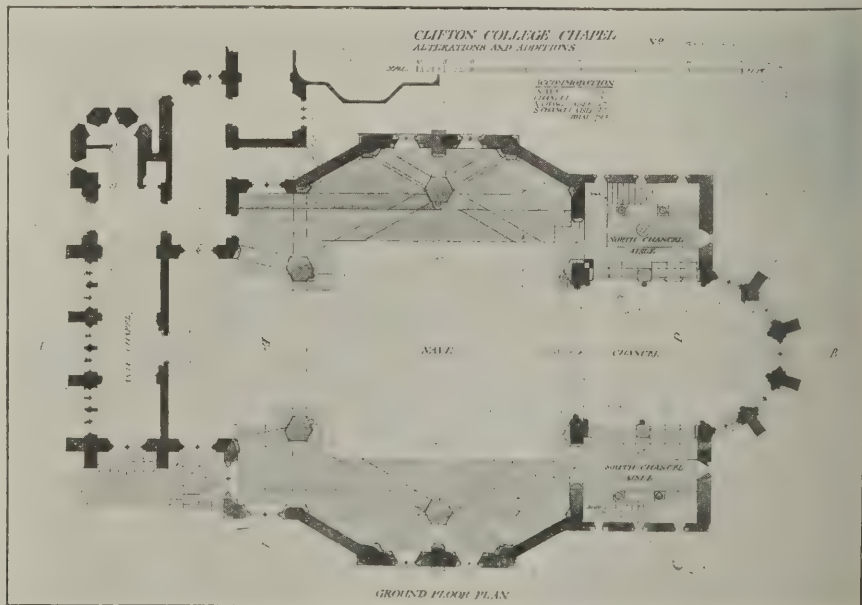

Additions to Clifton College Chapel.

THE chapel at Clifton College, Bristol, is a comparatively old building, having been begun in the 'sixties and enlarged subsequently by the addition of a north aisle. At the recent enlargement the east and west ends of the old chapel were retained, and a new hexagonal lantern with transepts was constructed in the centre, from designs by Messrs. Nicholson and Corlette, F.F.R.I.B.A. There is a crypt below the chapel, the extensions to which are vaulted in concrete.

The new walls are rubble built, with brick bond courses and internal quoins. The piers, arches, and ribs are ashlar work, and the vault cells are of concrete slightly reinforced. A large central area is thus obtained without piers or obstructions of any kind.

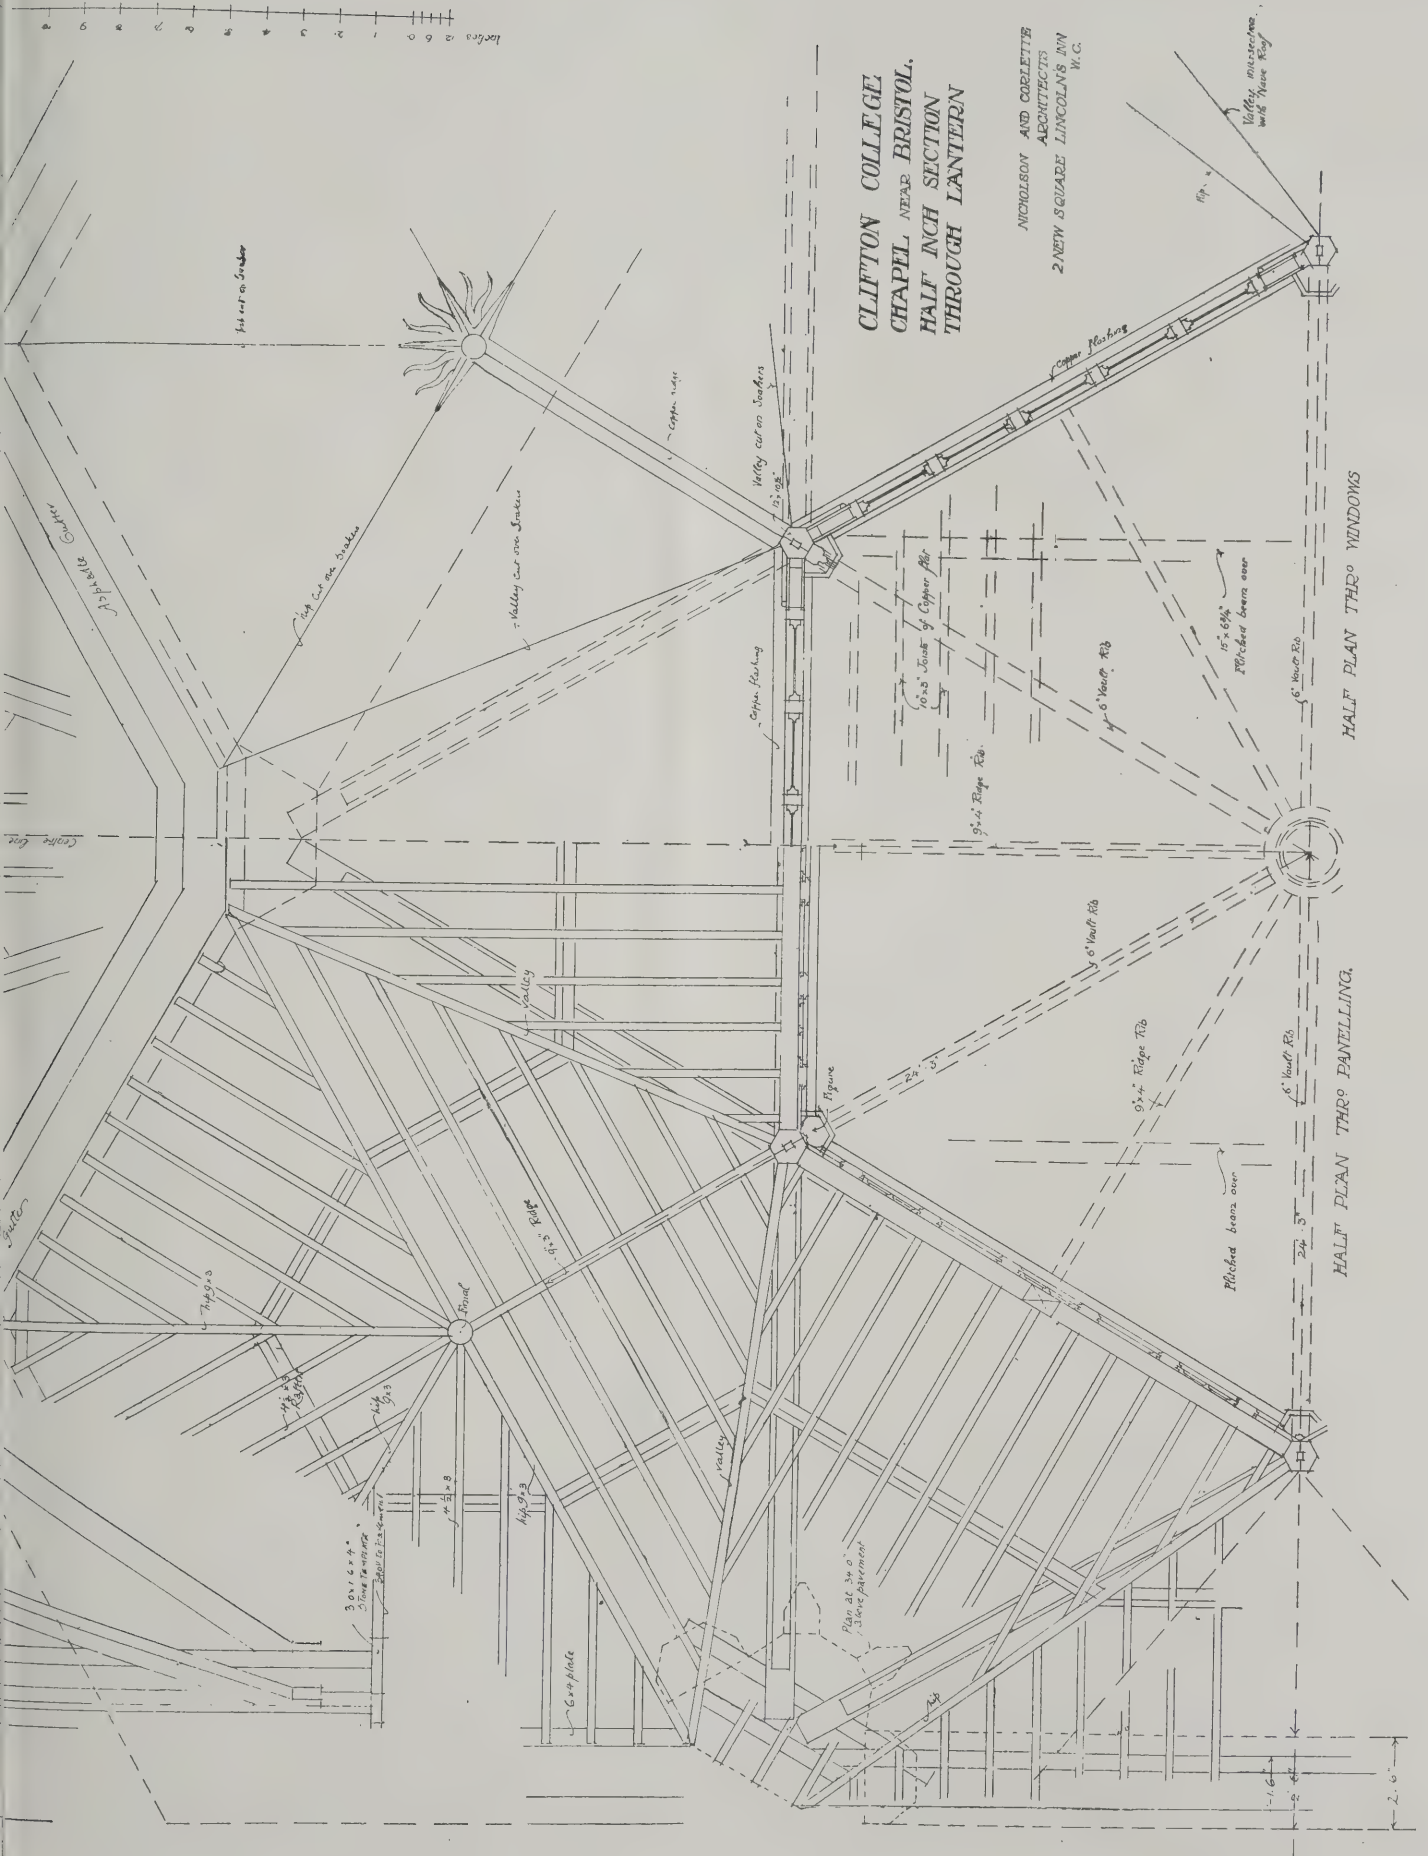

Above the vaulting is a timber lantern carried on six intersecting queen-post trusses, the queen-posts forming the angles of the lantern, which is placed eccentrically with regard to the lower hexagonal space. This lantern is of course self-supporting, and does not ride on the stone vaulting. The detail construction is shown on the drawing reproduced as Centre Plate in this issue. The windows are of teak, and the exterior is covered with copper.

The window dressings and other wrought stonework of the old chapel have been reused in the new work, so that very little new masonry was required except for the piers and vault ribs. The builders were Messrs. Cowlin and Son, of Bristol.

COMPETITIONS.

Scottish National Memorial to King Edward VII.

The designs for the Scottish National Memorial to King Edward VII., which is to take the form of an entrance to Holyrood Palace, have now been received by Sir Thomas Hunter, the Town Clerk of Edinburgh. The architects invited to compete were:—Sir Robert Lorimer, R.S.A.; Mr. G. Washington Browne, R.S.A.; and Mr. Hippolyte J. Blanc, R.S.A., all of Edinburgh; Mr. John J. Burnet, F.R.I.B.A., Mr. J. Miller, A.R.S.A. and Mr. H. E. Clifford, F.R.I.B.A., of Glasgow; and Mr. R. J. Macbeth, architect, Inverness. Mr. Macbeth died the other day, but judging from the fact that there are seven sets of designs (one of the competitors has sent an alternative design) it would appear that Mr. Macbeth's scheme had been completed before his death. The Executive Committee, who will adjudicate, are to be convened at an early date. After being examined by them, the designs will be sent to London for inspection by His Majesty the King, with whom the final selection will probably remain. A provisional estimate placed the cost of the memorial at £14,000 or £15,000.

Miners' Federation Hall and Offices, Bolton.

The award in this competition is as follows: 1, Messrs. Bradshaw, Gass, and Hope, 19, Silverwell Street, Bolton; 2, Messrs. Sykes and Evans, Salisbury Chambers, 7, Chapel Walks, Manchester; 3, Messrs. Thos. E. Smith and Son, Central Chambers, Fold Street, Bolton. The premiums offered were £50 and £25 for the two best designs. Mr. Jonathan Simpson, F.R.I.B.A., was appointed assessor. The designs are not to be exhibited.

Designs for Mural Paintings.

The Committee of the forthcoming Exhibition of Designs for Mural Paintings and for the Decoration of Schools, etc., announce a competition for the decoration of the vestibule of the Middlesex Hospital. Mr. Edmund Davis, a governor of the hospital, has generously arranged for the rebuilding of the entrance, with a view to mural decoration. The circular giving particulars may be obtained of the Hon. Secretaries, Mural Decoration Committee, Crosby Hall, S.W. From this circular the following particulars are extracted:—"Vestibule of the Middlesex Hospital, Berners Street, W.C.—Architect, Mr. Keith D. Young, F.R.I.B.A. The plans will provide for four wall-spaces, lit from the roof, each measuring 5 ft. 8 in. high by 10 ft. 11 in. broad. The architect proposes a dark wooden dado, preferably of teak, and a moulding for the paintings either of the same material, or of some other, at the discretion of the painters, and that outside the moulding should be a plain surface of white or light-coloured plaster. Plans

are on view at Crosby Hall, showing the arrangement and lighting. The subjects, it is suggested, should be symbolical such as "The Good Samaritan," or might be cheerful scenes of convalescence in the country or by the sea, or scenes of ordinary life at different times of the year. Each competitor is limited to one design, but the occasion is a good one for co-operation between several designers. Mr. Davis offers £100 for the execution of each painting from a design approved by him. In the event of a design being accepted and not approved by the Middlesex Hospital, the sum of £50 will be given in lieu of the execution of the work.

Bristol Society of Architects.

The annual general meeting of the above society was held on April 15th, when the Council and officers for the session 1912-1913 were elected as follows:—President, Mr. G. H. Oatley, F.R.I.B.A.; vice-presidents, Mr. J. Foster Wood, F.R.I.B.A., and Mr. Mowbray A. Green, F.R.I.B.A.; members of Council, Messrs G. C. Awdry, F.R.I.B.A., T. H. Weston, F.R.I.B.A., G. C. Lawrence, A.R.I.B.A., F. W. Wills, F.R.I.B.A., R. C. James, F.R.I.B.A., W. L. Bernard, F.R.I.B.A.; honorary secretary, Mr. C. F. W. Denning, Lic.R.I.B.A.; associate members of Council, Messrs. B. Wakefield, Lic.R.I.B.A., and A. B. Botterill, A.R.I.B.A. (honorary treasurer).

NICHOLSON AND CORLETTE, F.R.I.B.A., ARCHITECTS

THE R.I.B.A. CONDITIONS OF CONTRACT: SOME POINTS FOR REVISION.

BY A. SAXON SNELL, F.R.I.B.A.

The author, while suggesting that upon several grounds the R.I.B.A. Form of Contract is in need of drastic revision, and, in particular, that it should, if possible, be made much shorter, confined himself mainly to two points—the employment of sub-contractors, and the effect of the arbitration clause.

MR. SNELL thought it due to the Practice Committee to explain that what he had to say did not necessarily represent the Committee's present views. He was no longer a member of the Committee, and had not been in touch with its work for nearly two years. It must, therefore, be understood that he was writing as a "free lance."

The author opened his subject by quoting the preamble of a Memorandum drawn up by the Practice Committee and submitted to the Council in 1907, in which it was recorded that questions had arisen as to the effect of a building contract under the form of contract and conditions recommended for use by the R.I.B.A. These documents were settled in their present form in 1903 in conjunction with the Institute of Builders and the National Federation of Building Trade Employers of Great Britain and Ireland. The forms previously in use were settled in 1879, and gave considerable power to the architect. On the settlement in 1903 this was altered at the instance of the Institute of Builders. Certain matters dealt with by Clauses 4, 9, 16, 19, and part of 18, were reserved to the architect, but new words were introduced into Clause 30, which have been held to destroy the effect of a certificate given by the architect, and the arbitration clause was also widened so as to lay open to review every certificate whether interim or final, and (subject to certain reservations) every opinion and decision of the architect. From subsequent judicial decisions it appeared that the effect of these alterations is not only to deprive the architect's certificate of all finality as between the building owner and the contractor, but that an architect who has given a certificate which is successfully challenged by a building owner in an action brought by the builder to recover the amount so certified to be due to him, is liable to repay to his client the building owner the costs incurred in resisting the builder's claim. The decision in *Goddard v. Ferguson* appears to carry with it the conclusion that the architect acting under the present authorised form of contract is no longer in the position and clothed with the immunities of a "quasi-arbitrator." It would also seem to follow that under similar circumstances an architect no longer owes a duty of fair and impartial treatment to the builder. The position raises very important questions not only with regard to the position of the architect but also as to the position of the building owner and building contractor respectively.

These circumstances, Mr. Snell said, point to the necessity of some revision. It would be an advantage if we could evolve a shorter document, with all its clauses in proper sequence and without repetition or overlapping. It is mainly a question of careful drafting.

The two points with which the author set himself to deal were (a) the employment of special tradesmen as sub-contractors, and (b) the effect of the arbitration clause.

Sub-contracts.

In modern contracts it is not unusual to sub-let carting, plastering, plumbing, slating, etc. Possibly the arrangement makes for better work, especially if the sub-contractor is himself a master craftsman. As architects, we are concerned only to know that the sub-contractor can and will do the work properly. We do not interfere with the financial or any other arrangement between the parties. We stipulate only that our specification and drawings shall be followed, and that the contractor shall not thereby contract himself out of his liabilities under the contract with the building owner. In other words, we hold him personally responsible for the work of his sub-contractor. There are, however, special works included in buildings which are distinctly recognised as matters which are outside the scope of the building contractor's knowledge and experience, and such as he himself would always delegate to others. Further we insist that special tradesmen or master craftsmen shall be employed. We do not even allow him to select the particular tradesman or craftsman; we reserve that right to the building owner or ourselves as his agent.

As architects, many of us devoutly wish we could dispense with these special tradesmen, but experience teaches us that we cannot do so safely; and we have to put up with the extra trouble and even risk involved. It is too much to expect that the building contractor will see "eye to eye" with us in their selection, and in the amounts to be paid for their special work. To a certain extent, our action relieves them of responsibility, though it may debar them from making the best possible financial arrangements with these special tradesmen; but it should be so worked as to inflict neither loss nor inconvenience to them in the execution of their own work.

In these days of quick building and small profits a dilatory sub-contractor may cause serious delay and inconvenience; and many contractors feel that they should have more adequate means of control, and, more especially, the power to withhold payment. On the other hand, our experience teaches us that if this power is conceded it may be used for inadequate reasons, or for purposes which from our point of view are not legitimate.

It must be acknowledged that in Clauses 20 and 28 this matter is dealt with in a manner which meets the difficulty—almost. Indeed, it seems to hold the balance admirably between both parties. Clause 20 may be regarded as safeguarding the contractor, and Clause 28 the special tradesmen. Nevertheless the provision for direct payment to the latter by the building owner is an awkward

circumstance, which may yet lead to unexpected decisions in a court of law.

My own practice is to nominate the special tradesmen and to fix the net amount to be paid to them. I have a provision in the building contractor's contract that he must pay these special tradesmen in full such amounts as I may certify from time to time, and the amounts so paid are not included in any payment to him by the building owner until he (the contractor) can produce evidence that they have actually been paid. The case of *Crittall v. The London County Council* is sufficient justification for the apparently arbitrary nature of this last provision. My own limited experience leads me to believe that there is no half-way house between taking this strong line and that of leaving the contractor that full control over the special tradesmen which he exercises over his own sub-contractors, reserving to ourselves only the right of nomination and fixing the price to be paid for the work. I am not at all sure but that the latter is under all circumstances (and more especially in our interests) the better of the two methods; but I have had no experience of it.

Arbitration.

Perhaps the most serious defect of these conditions is that the architect is reduced to the level of mere agent for the building owner. He is deprived of judicial powers. It is a position which we think—to quote again from the memorandum referred to—"unfair to the contractor, not in the long run to the interest of the building owner, dangerous to the architect, and derogatory to the dignity of our profession." This dual position so long held by the architect has been challenged. It is an inconvenience in the eyes of a certain class of building owner, and an offence to his legal advisers. On the other hand, his Majesty's judges have generally upheld it as eminently reasonable.

It seems that lawyers are obsessed with the idea of "agency" in the architect's position, and to speak frankly I think they will always do all they can to deprive us of those judicial functions which they consider can only be exercised by members of their own profession. It is a very natural opinion, and not by any means based on selfish considerations. Their training and experience give them a better grasp of the principles of law and equity. Where, in our opinion, they fail is in their limited knowledge of the conditions under which a building is conceived and carried into execution, and their failure to perceive that supervising building work is in fact one long arbitration.

In the old form of contract, our final certificate was given this character of an award from which there was no appeal (except on grounds of fraud or collusion) by either party. On the whole the arrangement worked well, and it certainly did prevent a good deal of contention as between building owner and building contractor. In the present form no decision of the architect binds either party, and certainly not the final certificate. The architect is reduced to the position of mere agent to the building owner, and as such may be sued for exercising his judgment in a way which may not be endorsed by the arbitrator. The position is one of great difficulty; for it seems we can never be certain how far we can be made liable for any act or alleged default under a contract.

The building owner's case is that he has agreed to pay a certain sum for a

*Extracts from a paper read before the Royal Institute of British Architects, April 15th.

building constructed according to definite plans and instructions; and he is entitled to the exact fulfilment of the contract. He relies on the architect to see it is so fulfilled, and pays him for so doing. At this point we join issue with him. We say that the remuneration we receive is not sufficient to pay for the close and constant supervision which alone would enable us to say with certainty that every part of the contract has been fulfilled. Our supervision can only be occasional and general; and this is so far recognised that it is usual for the building owner to employ a clerk of works for the necessary daily and indeed hourly supervision of the work. It follows that our certificate can only mean that to the best of our knowledge and belief—gained from such general inspection—the work has been properly executed. Under these circumstances, and provided the architect's immunity is preserved, it seems reasonable that either party should have the right to question the Final Certificate; although I believe that in the long run, and in most cases, mutual acceptance is in the best interest of both parties. Immunity for the architect is however essential, and without it we are faced with very serious responsibilities for which we are very inadequately paid.

Failing the practicability of immunity, there are—as far as I can see—but two courses open to us—that is, either to restore our position as sole arbitrator (which gives us a measure of safety), or to employ, pay, and be responsible for, the clerk of works; and insure against our responsibility at Lloyds or elsewhere. We should, however, have to raise the amount of our commission to meet the extra cost to us.

I do not suggest scrapping the present Conditions of Contract; but they might certainly be shortened, simplified, and divested of the underlying suggestion that building is—as a genial member of the Institute lately put it to me—a “rogue's trade.” Building owners and contractors alike may well ask themselves whether on economical grounds alone it is worth while to quarrel. A careful examination of the records of building actions affords convincing evidence that in most cases only the lawyers and expert witnesses benefit.

DISCUSSION.

Mr. Harrison, proposing a vote of thanks, said the Institute “Conditions” had taken five years to elaborate, and personally he thought they were good. He dwelt at considerable length upon the papers read by Mr. White and Mr. Greenop before the Institute in December last, contending that the cases adduced by the lecturers revealed no new responsibilities for architects. With reference to sub-contractors, the speaker mentioned incidentally that by the Conditions of Contract an architect only had power to nominate, select, or approve. In conclusion, Mr. Harrison said he thought that the only remedy for the present unsatisfactory condition of affairs was for the architect to give more strict attention to the business side of his profession, and to cultivate more business-like habits. When it had been necessary to do business by telegram or telephone, for instance, in order to remove any possibility of misunderstanding, an architect would be well advised to dictate a letter at once saying how he intended to act. To ensure proper supervision, architects might charge a higher fee and employ their own clerk of works. The fact remained that architects were agents in the eye of the law, and as such were

liable to be called to account for any neglect in services rendered to clients.

Mr. Atkin Berry seconded the vote of thanks, commenting adversely at some length upon certain of Mr. Greenop's conclusions.

Mr. William Woodward said he believed there were no newer responsibilities for architects; there was, however, more desire on the part of clients to bring into the law courts those cases which forty or fifty years ago were settled outside. The Conditions of Contract, he noticed, did not give the architect power to withhold payment from the general contractor until he (the architect) had seen the receipt of the sub-contractor, a power with which he thought the architect should be invested. With regard to arbitration, he (the speaker), if he were a contractor, would not sign a contract where the architect himself was left sole arbitrator. There was always the grave risk of personal bias.

Mr. Douglas Mathews said it was largely through workmen's want of interest that so many deficiencies occurred in modern work. If an architect could not be trusted, and had to introduce outside arbitration whenever a dispute arose, a building would never be finished.

Mr. Love described the practice with regard to contracts in foreign countries, mentioning that in Spain two architects were employed on one building—one for the builder, and the other for the building owner. He suggested that in England architects might with advantage entrust the duties of clerk of works to an office assistant.

Mr. H. D. Searles-Wood said that a contractor's responsibility ceased when he got his final certificate, but the architect was liable for a period of six years.

Mr. Blanco White said an architect had no authority to vary plans without the building owner's consent. He suggested that an architect should guard himself by inserting in an agreement a clause to the effect that plans would perhaps be varied as the work proceeded from time to time. With regard to sub-contracts, architects, in asking for tenders, should say whether the contract would be with themselves or the contractors. All contracts, too, should be signed “I accept,” and not “on behalf of.” As to whether an arbitrator would be liable to an action, in so far as he was an agent he would be.

Mr. Alan Munby, Mr. G. E. Nield, Mr. Douglas Wood, and Mr. Matt. Garbutt, having spoken,

Mr. Max Clarke suggested the insertion of a clause giving the architect power to demand the production of receipts of payments to sub-contractors. He thought there was too much trouble about the form of contract and not enough about the carrying-out of buildings.

Professor Blomfield, in summing up the discussion, said, with respect to sub-contracts, that he made a practice of having, not a special sub-contract, but a direct contract. Architects, he felt sure, did not want to avoid their legitimate responsibilities; but they did certainly resent having to pay for things which they could not possibly control.

Mr. Saxon Snell, Mr. W. Henry White, and Mr. Edward Greenop then replied.

The Lord Lieutenant of Ireland has promised to be present at the annual dinner of the Royal Institute of the Architects of Ireland, which has been fixed for May 7th.

ARCHITECTS' BENEVOLENT SOCIETY

The sixty-second annual general meeting of the Architects' Benevolent Society was held at the rooms of the R.I.B.A., 9, Conduit Street, on April 11th, Sir Ernest George, A.R.A., in the chair.

On the motion of the chairman, the annual report of the Council (from which extracts are here given), was adopted:—

“In submitting their sixty-second annual report, the Council regret that they have again to record a diminution in the amount of the Society's subscriptions. The difference is small as compared with last year, but it is significant in view of the fact that a special letter of appeal was issued by the President in October to over five thousand architects practising in the United Kingdom. The result of the appeal, although scarcely realising anticipations, increased by new or additional subscriptions the total amount received by £41 18s. 6d. while the sum of £124 8s. 6d. was added to the Society's capital from donations received in response to the appeal. The Council feel that the number of contributors on the Society's books (the total number of subscribers is 512) is inadequately representative of so large a profession. It is felt that the subscription list must mainly rely for its support upon the efforts of individual members and upon the corporate action of the metropolitan and provincial architectural societies.

“During the year the sum of £1,03 was distributed in relief; £245 being paid to pensioners, while £786 was disbursed in grants among seventy-four applicants. A pension having become vacant, various applications were considered, and the annuity was finally granted to the widow of an architect.

“The total amount received in subscriptions was £707 5s. 6d. (as compared with £716 14s. received in 1910); while the amount received in donations was £296 14s. (as compared with £109 15s. received in 1910), including Professor Aitchison's bequest of £90. With the amount carried forward from last account together with the donations received during the year, the Council were enabled to increase the Society's investments by the purchase of £500 Queensland 3 per cent. Inscribed Stock at a cost of £42 14s. 6d.”

Sir Ernest George announced, among other recent contributions to the Society's funds, a legacy of £200 from the late Mr. T. M. Rickman.

The Council were elected as follows:—

President, the President of the R.I.B.A.; vice-president, Mr. Henry L. Florence; Sir A. Brumwell Thomas, Mr. Walter Cave, Mr. F. W. Hunt, Mr. Reginald St. A. Roumieu, Mr. Lewis Solomon, Mr. T. E. Colcutt, Mr. George Hubbard, Mr. E. E. I'Anson, Mr. A. Saxon Snell, Mr. W. L. Spiers, Mr. Henry Lovegrove, Mr. E. Arden Minty, Mr. Rowland Plumb, Mr. William Woodward, and the President of the Society of Architects.

Mr. W. Hilton Nash and Mr. Percival Currey (who was absent through illness) were thanked for their work during the past year, and re-elected respectively as hon. treasurer and hon. secretary.

A vote of thanks was accorded to Mr. C. H. Brodie and Mr. Henry Lovegrove for auditing the Society's accounts. After further expressions of thanks to Mr. Dircks for his conduct of the Society's affairs, and to Sir Ernest George for presiding, the meeting terminated.

NEWS ITEMS.

Change of Address.

The British Reinforced Concrete Engineering Co., Ltd., announce that they have moved their headquarters from 196, Deansgate, Manchester, to 82, Victoria Street, Westminster.

Cleaning Winchester Cathedral.

Winchester Cathedral will be closed to the public from Monday last, April 22nd, to May 4th, inclusive, in order that the building may be thoroughly cleaned after the six years' work of repair.

Bath Attendants as Painters.

The Manchester Master Painters' Association have decided to support the protest of the operatives against the action of the Baths Committee of Manchester Corporation in employing bath attendants to do painting work during the slack season.

Extension of Hampstead Garden Suburb.

The success which has attended the Hampstead Garden Suburb, particularly on the co-partnership side, has led to the Co-partnership Tenants' Society's obtaining another 300 acres, making in all over 450 acres in possession of the society. The whole of this will be developed on modern town-planning lines.

An Architectural Exhibition.

The Allied Artists' Association, 67-9, Chancery Lane, London, W.C., announce that they desire to make architecture a salient feature of their fifth annual London Salon, which will be held next July in the great arena of the Royal Albert Hall. The exhibits may consist of plans, models, drawings, or photographs of elevations.

"Georgian" Drawing Pencils.

We have received from Messrs. W. H. Smith and Son a batch of "Georgian" drawing pencils. At the present day one is accustomed to use black leads of the highest quality, and we find these pencils to be up to the best standard. They are admirably finished, and the name printed on each is itself an example of good lettering. They are obtainable in nine grades—namely, HB, B, BB, BBB, F, H, HH, HHH, and HHHH.

Exterminating Insect Pests.

Messrs. R. Sumner and Co., Ltd., manufacturing chemists, Liverpool, have drawn

SUMNER AND CO.'S SPRAYING APPARATUS.

our attention to a new spraying apparatus they have just brought out for the effective distribution of their well-known insect exterminator solution "D," as described in our issue of March 20th, p. 311. The sprayer (of which an illustration is here given) is operated on the same pneumatic principle as the original one, but holds nearly four pints instead of one. When a large area (such as the steerage quarters of a ship, or a block of buildings) has to be treated, the increased capacity of the new sprayer is a distinct advantage, as the labour is thereby reduced to a quarter. Messrs. Sumner and Co. have in this later machine carried still further their principle of simplification of the parts, and with it there is practically nothing to get out of order. This sprayer is very strong and particularly well made. We are informed that solution "D" is now being used by most of the leading shipping companies, public-health authorities, and many property owners, for the destruction of bugs, cockroaches, and other insect pests.

Affairs of a Well-known Building Firm.

At the Salford County Court, on April 15th, Messrs. William Brown and Sons, the well-known builders and contractors, of Trafford Road, Salford, were granted by his Honour Judge Stanger an immediate discharge from bankruptcy. Mr. J. Grant Gibson, the Official Receiver, reported that the first meeting of creditors was held in September, 1909. The amount involved was £72,721.

St. James's, Alperion.

The Bishop of London consecrated the new Church of St. James's, Alperion, on Easter Eve, this being his first public appearance since his return home from the consecration of Khartoum Cathedral. The new church, which lies between Wembley and Perivale, provides accommodation for 750 persons, and consists of nave and aisles, a morning chapel being upon the south side of the chancel. The church is built of brick, with red dressings and Casterton stone externally; Farleigh stone being used internally, with plastered walls. The roofs are covered with hand-made tiles. A narthex extends over the west front. The cost is about £7,800. The architect is Mr. William A. Pite, F.R.I.B.A.

Dutch Architecture.

At the last meeting of the Birmingham Architectural Association the vice-president (Mr. G. Salway Nicol) read a paper on the Association's visit to Holland. The great charm of Dutch buildings, he said, is due to the fact that they are such a complete expression of the character and ideals of the people. Their domestic work particularly has much to teach us in the simple and direct way they obtain their effects. For their more important buildings, such as the "Stadhuis" at Middleburg, they generally employed a phase of the Gothic style directly inspired by similar buildings in Belgium, but at the same time the detail is full of native feeling. The Abbey buildings at Middleburg, and the Town Hall and Church at Veere were shown by many sketches made by the members, and the great influence of Dutch work in England in the seventeenth century was pointed out.

LONDON SOCIETY OF MASTER DECORATORS.

At the general quarterly meeting of this association, held at the Holborn Restaurant, Mr. John Anderson, president, in the chair, the first business was to invite the views of the meeting with reference to the National Insurance Act, and to receive the report of the Special Committee on the subject.

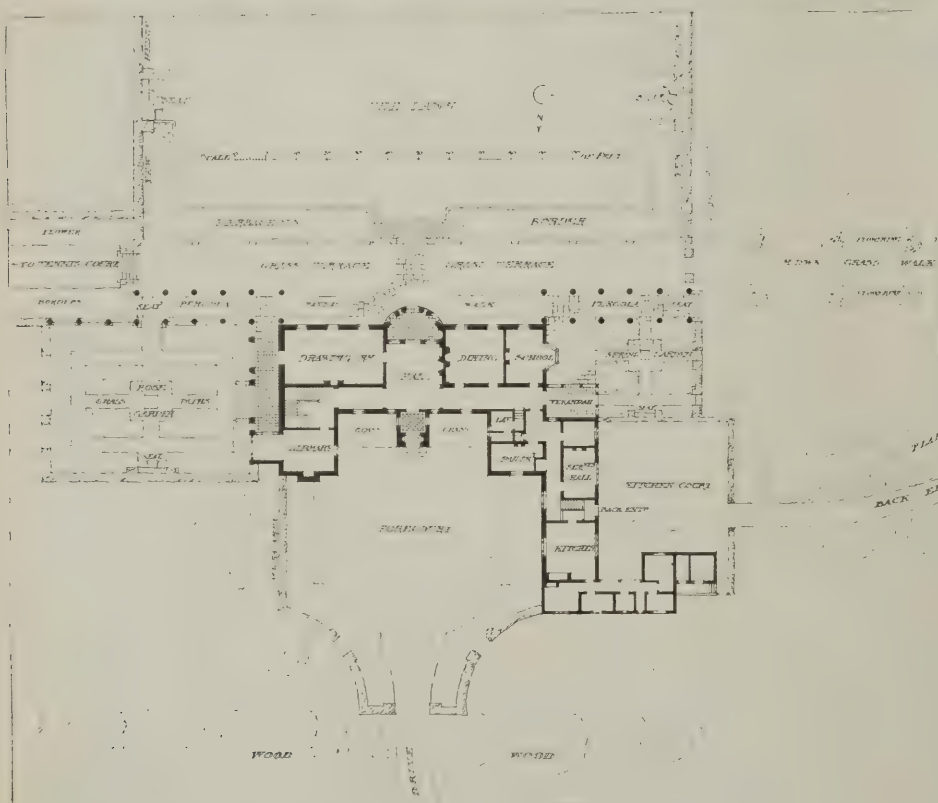

The first objection taken to the Bill was that it had not received adequate discussion before it was passed.

A member asked whether it would not be a waste of time to discuss the matter now that the Bill had become an Act, but the President held that a discussion would be useful; there were other associations who were taking action, and it might be advisable to join with them.

Mr. Renshaw thought that the Government should be told that this association was not in favour of the Act, because it placed very onerous conditions on all masters and employers of labour. He moved the following resolution: "That this meeting of the London Association of Master Decorators hereby resolves to join hands with the Employers' Parliamentary Association at Manchester and any trading or employers' associations having similar views, to ask for a full and proper reconsideration of the National Insurance Act before it is put into force, in order that the views of employers generally and workers may be put before Parliament before the 15th of July." This resolution was carried unanimously. After further discussion, it was agreed to confer with the London Master Builders' Association, to see whether there was any possibility of taking joint action in making representations to the Government.

A discussion ensued on the Education Committee's report with reference to the action which should be taken by the society in response to a London County Council circular on technical education for painters and decorators, in which questions were asked and suggestions invited. It was agreed that the Education Committee should continue its work, and the hope was expressed that members would make up their minds to contribute towards a scholarship fund.

The President said the next business was to resolve as to the issue of employment and discharge cards. The Committee had been considering the question of issuing to men employment cards, which they could carry about with them, and on which would be entered the fact that they had been working with a certain firm for a certain length of time, so that it might be assumed they had some proper and practical knowledge of the trade. At the present time men simply said that they were acquainted with the trade, when they were found to know very little about it. If such a card as was proposed were insisted upon it would give some indication of the fact. The Council had had some forms printed, and estimates obtained for printing a large quantity. It was proposed not only to issue those of the association, but to write to other master decorators who had not yet joined their body, asking them if they would issue the cards to their employees, for their own satisfaction. It was not intended to give the men characters in this way. In the first column would be the name and address of the man, and other columns would show the date of his employment, his rate of wages, the date of his discharge, etc. He felt sure that a man who could prove these facts would

Plan of House and Garden.

"SHORNE HILL," NEAR TOTTON, HAMPSHIRE. ERNEST WILLMOTT, F.R.I.B.A., ARCHITECT.

get the preference. There was no need to trouble this meeting with the details, and it would perhaps be best to leave the committee to proceed on the best lines they could, unless members wished to see the form proposed. It would be a linen card, so that it could not be readily torn. The cost would not be great, and they would be issued to the firms at the actual cost.

Mr. Renshaw said he was glad it was intended to issue the cards to masters who were not members of the association

as well as to members. It might mean an expansion of membership. Another question was, whether the committee thought of issuing the card to the Painters' Union, and whether that union was likely to raise an objection.

The President considered that the suggestion to communicate with the Painters' Society was a good one; they could have no valid objection.

Mr. Dakin pointed out that if the suggestion to send the card to all the master decorators who were not members of the

association were carried out it would mean a big expense. For each workman in the trade to have one would mean something like £100. One must go to work carefully about that.

The President said there was no idea of giving them away.

Mr. Renshaw thought a better way, before contracting a large expense, would be to put it to the union whether they were willing to co-operate, and if so, send a sample round and ask them if they would be willing to pay for them.

The proposal was agreed to.

The President said the next business was the question of co-operating with the Paint and Varnish Society in the reading and discussion of papers. Provided the members agreed to the idea, it did not need much discussion, for, with that approval, the committee would take steps to arrange meetings. The papers would be read by members of both associations for mutual benefit. This proposal was agreed to.

CORRESPONDENCE.

"Some Notable Buildings in Budapest."

To the Editor of THE ARCHITECTS' AND BUILDERS' JOURNAL.

SIR.—Your excellent article on this subject will give your readers a good idea of the architectural beauty of the capital of Hungary. It is true, as you state, that this city has been recently rebuilt, yet at the present time, building operations on an unprecedented scale are going on in the central part, which, on completion, will greatly add to the magnificence of the city. This activity is due to the fact that the civic authorities offered remission of taxation for a long term in respect of buildings erected within a definite period.

Now, may I in a friendly spirit point out a few spots on the sun? Although I have known Budapest for many years, I did not, when first reading your article, understand what was meant by "Donauzeile" and "Kettenbrücke."

For these are German names, and such are not generally or officially used in Hungary. Equally unfamiliar are "Strasse" and "Platz."

When writing about Hungarian places for British readers, I suggest that either Hungarian or English names should be used. This has been done recently in Bradshaw's Guide, and by several map publishers.

In stating that Budapest is the capital of "Austria-Hungary," you are too kind.

Budapest is the capital of Hungary, just as Vienna is the capital of Austria.

There is no capital of "Austria-Hungary," because there is no one State or Empire to which that name can be correctly applied. In this country, we have erroneously supposed the existence of such an Empire; yet really there is no Austro-Hungarian territory, there are no Austro-Hungarian subjects, no Austro-Hungarian laws. Where, then, is the Empire?

Austria and Hungary are free and independent States, which, for the purpose of mutual defence, have agreed to unite their naval and military forces and to be represented in foreign lands by the same diplomatic agents. But in all the agreements which have been made, Hungary has expressly declared that in agreeing to this limited joint action, she did not relinquish any of her independence, and did not thereby become part of any other

State or Empire, but would remain an independent State of equal rank with Austria.

And this is her status at the present day.

W. H. SHRUBSOLE.

'We have [received with Shrubsole's letter a series of five well-illustrated booklets, entitled respectively: "Budapest and its Environs," "The Northern Highlands of Hungary," "The Hungarian Lowlands and Transylvania," "The Transdanubian District and the Hungarian Coast." Each booklet contains about fifty pages, and more than fifty photographic illustrations, and is enclosed in an artistic cover. Either or all can be obtained, gratis and post-free, from the Director of the Royal Hungarian State Railways, Ardrassy ut, 73, Budapest, Hungary.]

The Architectural Association Sketch Book.

To the Editor of the ARCHITECTS' AND BUILDERS' JOURNAL.

SIR,—I notice in your issue for April 17th, in a review of the "Architectural Sketch Book" for 1911, the following passage occurs: "The 'First Quarterly Part, 1911,' which is the official description of the last issue of the Sketch Book, etc." May I point out that a letter was sent you with the plates stating that they comprised the complete volume for 1911?

F. R. YERBURY,
Secretary, The Architectural Association.

THE CORROSION OF STRUCTURES.

In considering the design of structures it is usual to base the first estimate of strength upon the assumption that the materials will remain unaltered; and afterwards to allow a factor of safety to take account of the ravages of time. If the structures contain iron or steel exposed to wind or water, corrosion is to be expected sooner or later, and the designer is forced to face the difficulty in one or more of three ways. He can increase the weight of the metal to provide for surface changes, he can prepare the surfaces and apply preservatives, or in certain cases he can allow for the cost of a staff to keep the structure under observation and to maintain the surfaces. The causes of corrosion are now fairly well known, but the best way to prevent corrosion is not so well understood, and a great deal of research is necessary before the conditions giving the best chances of durability can be regarded as settled. In many instances it is impossible to avoid exposure of iron and steel surfaces, but engineers would do well to consider whether special precautions cannot be taken at reasonable first cost with vital parts of such structures. For example, although it may be difficult to protect the interior of iron pipes it may be quite practicable to replace iron valves in the pipe-line by a more durable metal. Again, it is often possible to reduce the evil of corrosion considerably by employing cast iron instead of wrought iron, and

there is no doubt that reinforced concrete is destined to be increasingly adopted in specific cases where corrosion is to be expected with bare or painted metal. Among the most curious instances of corrosion must be included the complete decay in some localities of imperfect alloys of the German silver group, and it is well known that copper wire in some circumstances fails in an obscure manner. —(From the "Times" Engineering Supplement.)

"SHORNE HILL," NEAR TOTTON, HAMPSHIRE.

This house is set among well-wooded surroundings, the approach road being cut through a small wood on the estate. The ground slopes to the south and south-east, a glimpse of Southampton Water being caught from the eastern stoep. The walls are of brick, finished with smooth plaster and whitewashed. Chimneys are of Basingstoke bricks (2 in.) and roofs are of local tiles. By desire of the owner, there is a suggestion of Cape Dutch in the style. The architect was Mr. Ernest Willmott, F.R.I.B.A., of London, to whose design also the garden has been laid out. The principal doors and floors and the main staircase are of oak; the wood beams and ceilings, as well as some of the bedroom doors, being of Oregon pine stained with "Solignum." Messrs. Wm. Johnson and Co., Ltd., of Wandsworth Common, were the general contractors.

"SHORNE HILL," NEAR TOTTON, HAMPSHIRE; GARDEN FRONT. ERNEST WILLMOTT, F.R.I.B.A., ARCHITECT.

PICTURE EXHIBITIONS.

The Fine Art Society.

At the gallery of the Fine Art Society there is a new collection of the grand but somewhat gloomy etchings of Mr. Brangwyn, who produces his effect mainly by great opposed masses of light and dark. The effects are such as, to say truth, we never see in connection with actual buildings in actual light; but it may be admitted that it is one of the functions of etching, as the finest form of Black and White art, to extract from a subject the most powerful effect of which it is capable. The finest etching in the collection is "The Breaking-up of the *Duncan*," showing the hull of an old ship towering up to the top of the picture above a low sight-line. "Cannon Street Station" is a powerful effect made out of an ugly subject; "The Bridge of Sighs" is a fine treatment of that familiar erection; and there is what might be called a grim power in the small etching of "The Bridge of Alcantara"—the Alcantara of Sicily, not of Spain; but one may ask whether in Sicily any such gloomy effect is possible. There are various water-colours, some of which seem to have been preliminary studies for the composition of the etchings; some are groups of working men called "a set of decorative drawings"; decorative they may become when treated in colour; in their present form they hardly merit the adjective. The large etching of "The Crucifixion" we dislike extremely; it is a piece of brutal realism. Artists who treat so tragic a subject in religious history should do so with some feeling for its pathos and significance.

The Leicester Galleries.

At the Leicester Galleries there is exhibited, in the first place, Mr. Walter Crane's portrait of himself painted for the Uffizi Gallery at Florence, where a collection of portraits of eminent artists, mostly painted by themselves, has been long in course of formation. The portrait is a half-length showing the artist in profile, with palette in hand at work on a picture. It is rather hard in style, but is a good likeness and is dignified in expression and design. Accompanying this, in the outer room, are a number of Mr. Crane's line drawings of illustrations of Spenser's "Faerie Queene" and some modern books. Most of these are well known; but there is also an interesting collection of early water-colour and gouache drawings done in Rome and South Italy many years ago, and not before exhibited. Many of these are architectural subjects, and the Roman subjects formed part of a group at the recent exhibition in the Castle of St. Angelo; ten of them were purchased by the Italian Government for the Corsini Gallery in Rome.

In the next room is a collection which gave us an agreeable surprise, Mr. Henshall's series of water-colours of "Cottage Folk." Mr. Henshall is a member of the Society of Painters in Water-colours, whose pictures at their exhibition we have never been able to like; they have been too pretentious and stagey in style. But the business of endeavouring to depict the simplicity and sometimes the pathos of the life of the poor seems to have been entered into by the artist with a sincerity and an absence of all mere striving after effect which give quite a new kind of spirit to his work; his children and old people are delightfully natural, and the groups are all well composed, and in some instances the small pictures show remark-

able qualities of colour. It seems as if Mr. Henshall's gift really lies in painting small pictures of this class; they are far superior to the larger and more ambitious works by him which generally figure at the Water-colour Society's exhibitions.

But the principal attraction at the Leicester Gallery is undoubtedly the series of water-colour sketches—they are mostly not more than sketches—by Mrs. Laura Knight. The sketches of ballet-dancers, "Impressions from Les Sylphides," we do not care for; they are cleverly done, of course, but serve chiefly to show how very ungraceful ballet-dancers' attitudes for the most part really are. The real successes of the collection are the broad, bright, airy sketches of landscape, with generally a figure or two, not worked up much in detail, but always with a sense of composition and of the expression to be derived from the design and balance of the figures, and their place in the landscape. These are works of true artistic genius. Mr. Harold Knight's contributions to the exhibition are mostly finished pictures, good in treatment and suggestive in design. But it is in Mrs. Knight's work that the real value of the exhibition consists.

The Goupil Gallery.

The Goupil Gallery contains collections of the works of three artists. Of those by Mr. Wolmark we prefer to say as little as possible; there is nothing among them as preposterous as the exhibit at the Grafton Gallery called, if we remember right, "A Decorative Study" but we dislike them wholly. The water-colours by Mr. David Neave, in the centre room, include some very good landscapes, especially those dealing with water and shipping. "After the Thunder" is a very true study of weather effect. In the third room are oil-paintings by Mr. W. J. Leech, R.H.A.; "Visions of Switzerland, Venice, etc.," somewhat visionary they are in style, but the artist has a fine perception of effect in snow scenes, as in "Blue and White"; "Glion"; "Above the Mists"; and "The Mountains." "The Sea, from the Lido," is a good bit of sea study; but in general, Mr. Leech's successes seem rather limited to one type of effect, which he treats very well.

The Indented Bar System.

The Indented Bar and Concrete Engineering Co., Ltd., Queen Anne's Chambers, Westminster, show, in their recently issued 1912 catalogue, a large number of views of works in which their system has been adopted, as well as several diagrams and other illustrations in elucidation of the system. The indented bars are rolled in two forms, respectively known as "rounds" and "squares," of which the weight per foot is in each case approximately the same as that of a smooth square or round bar of the same nominal size. In accordance with the ordinary specification, the bars are rolled of medium steel, with an elastic limit or yield point of 50,000 lb., and an extension of not less than fifteen per cent. in a length of 8 in.: that is to say, the elastic limit is nearly twice as great as that of ordinary mild steel. The breaking strength is 90,000 lb., or 40 tons per square inch. A considerable saving in the weight of steel required for a given strength is therefore claimed, while, it is further stated, the factor of safety can be increased without extra cost. The adaptability of the system to very various classes of work is well shown by the illustrations included in the catalogue.

IPSWICH BUILDING TRADES
ASSOCIATION.

The annual dinner of the Ipswich Building Trades Association was held last week at the Crown and Anchor Hotel, when the President (Mr. B. Bird) occupied the chair over the largest number of members and friends who have sat down at the annual gathering.

The usual loyal toasts having been duly honoured, Mr. R. Smyth proposed "The Mayor and Corporation of Ipswich." He suggested that if the Mayor and Corporation had a surplus in their funds at the end of the year, the builders of Ipswich should be the first men to be partakers of it, because the builders of Ipswich had been hard hit during the last few years, owing to the stringency of the contracts. He appealed to the Council to give the town a better appearance than at present, for the main entrance from the station was like a scrap-book owing to the great number of hoardings.

In response, the Mayor (Mr. F. B. Rands) said that the Corporation were not responsible for the hoardings, but steps were being taken at the present time for the Corporation to have a larger control than at present over such hideous erections as were being put up in various parts of the town.

Mr. C. E. Whitmarsh, in proposing the toast of "Success to the Ipswich Building Trades Association," said that in the building trades there were broad outlines in which co-operative agreement might be reached without interfering with the individuality of the man, because, however close they might draw rules in any association, they would find that the individuality of the person must be allowed for. There was one way in which they could co-operate, and that was in the raising of prices to a living limit, because at present it was all work and no profit. The trade engaged the second largest body of men in the country, but in no trade was the profit so little in comparison with the wages paid, and it was on lines similar to these that associations such as theirs could do a great deal of good. To use the language of the day, it was time the builders struck for a minimum profit.

Mr. A. Sadler, who was called upon to respond, said that the association was a useful institution, and worthy of more support than it got. They had made some little change during the last year or two in introducing other subjects than purely business matters, educational subjects connected with the trade, very interesting and very instructive to all, and they were finding that they were of great assistance, helping them to take a keener interest in their work.

Mr. E. E. Saunders, who also responded, said that at one time it looked as though the association would fall through, but the widening of its basis to bring in kindred trades had given it a new lease of life.

Mr. A. W. Warner proposed the toast of "The President and Officers," and Mr. Buckingham Bird, in response, said that in the building trade proper few had retired in affluence, and quite half had finished up in the Bankruptcy Court, or dependent on charity. One of the great difficulties of the trade was that no builder could say what proportion of profit he was going to get as compared with the wages he paid.

Mr. C. Borrett, hon. secretary and treasurer, said that financially the association was in a good position.

CONCRETE AND STEEL SECTION.

(MONTHLY.)

Bending- Moment Formula.

It has been several times stated in this journal that the commonly accepted formula for bending moments in

beams, $\frac{wl^2}{12}$ should not be regarded as a rigidly fixed law, but that it should rather be taken as depending upon variable conditions. This view is emphasised by the authors of an admirable manual on "Reinforced Concrete Design," by Oscar Faber, B.Sc., and P. G. Bowie, assistant engineer to Messrs. Trollope and Colls, Ltd., London (London: Edward Arnold, 41 and 43, Maddox Street, W.; pages xx + 332, 8½ in. by 6 in., price 12s. 6d. net), which is apparently the most recent of the rapidly growing number of treatises on the subject. The ratio of live to dead load, the relative stiffness of beams and columns, etc., are in this treatise subjected to mathematical treatment with the view of arriving at suitable formulæ taking them into account; and the appendices in which these calculations are shown would alone be a sufficient justification for the issue of this treatise; which, however, comprises much else that is valuable.

Pest-Proof Material.

There is, for instance, an exhilarating freshness in the style. Thus, in enumerating the special advantages of reinforced concrete construction, the authors not only mention rot and the attack of pests such as the *Teredo navalis* in marine structures, and the white ant and such vermin above ground, but add that "in some cases *Homo humanus* might justly be included in this list, as he not infrequently plays havoc with any removable timber"—an observation of which certain effects of the coal strike will probably reveal the truth and beauty. Again, the authors wisely and justly admit that the claim of reduced first cost cannot be made in all cases. "It may be taken for granted, however, in this age of commercialism, that where it [reinforced concrete construction] has been adopted, it has always had a reduced ultimate cost, when its absence of upkeep and other properties are taken into account. It is not now the custom to erect a structure in the best possible material as well as we know how, simply for the joy of doing a thing supremely well—this belonged to the old-world civilisation of Greece, and is, unfortunately, foreign to us."

The Principle Re-stated.

The fundamental principle of reinforcement is well expressed: "To supply the requisite tensile strength to our material, steel bars are embedded in the concrete where tensile stresses are anticipated—for instance, at the underside of a freely supported beam. If this is done consistently, we have, qualitatively, the key to the greater portion of reinforced concrete design, and it merely remains to calculate, from ordinary scientific principles, the quantity of such reinforcement required. It should be noted, however, that the mere embedding of steel bars in the concrete would not produce a reliable com-

posite material, except for two extremely fortunate circumstances, which were probably not realised by the pioneers of its use. The first is the fact that concrete contracts slightly during setting in air, and, in contracting round a steel bar, holds it tightly in such a way as to prevent the steel from slipping, even when no hooks or even roughnesses exist on the bar. The second is the fact that steel and concrete have practically identical coefficients of expansion, and consequently a uniform change of temperature does not involve temperature stresses in the two component materials." That is clear enough, although a foreign reader might find himself in momentary doubt of the precise interpretation of "even roughnesses."

Specialists' Calculations.

The book is divided into four parts, the first part dealing with the calculation of stresses under known forces and moments; the second with the design of columns; the third with the design of beams and slabs; and the fourth, entitled "Applications and General Notes," contains chapters on retaining walls, specifications, quantities, and notes on practical applications of reinforced concrete, and on the specialist engineer and the contractor. In the chapter last denoted, there is a further specimen of the somewhat grimly ironical humour that the authors occasionally use with terse and telling effect. They contend that only those who have made a life-study of reinforced concrete are fully aware of the extent to which the published calculations of specialists can be dangerously misapplied. "Such reports," they say, "as that of the R.I.B.A., and the many regulations, particularly those issued in France, have undoubtedly done much to lead engineers along the right lines. But it is a long step from that to the idea that every man should now design his own concrete work. It is not denied that he can, and that if he makes his factor of safety sufficiently large to cover 'factors of ignorance,' his work will stand, provided some important consideration has not been inadvertently ignored. But even so, his work will be more expensive than that of the specialists, since on the one hand he has to find by laborious methods what a specialist has trained himself to see almost instinctively; and, secondly, because his 'factor of ignorance' must be greater, and will therefore entail the use of more material to secure an equally safe structure." For these and for other reasons, the authors are confident as to the assured position of the specialist, whose "mastery is as great as ever," and who "still holds valuable information on questions which outsiders have not yet dreamt of, and [who possess] answers to difficulties which they brave in ignorance only." There can be no doubt that in the main this contention is true, and is not greatly discounted by the fact that it is put forward by specialists.

Conditions of Success.

The section under the heading "The Contractor," is valuable as embodying deductions derived from close observation

in practice. It is held that serious error may be made unwittingly by a conscientious contractor; and, "again, the drawings supplied by the specialist may not be sufficiently clear, especially when it is remembered that they are to be read by a foreman with no particular qualifications for solving Chinese puzzles"; and the final word is to the effect that the conditions ensuring the least danger from bad workmanship or want of understanding between drawing office and works may best be secured when a competent engineer employs his own staff of foremen thoroughly trained to his designs and methods. This tendency to discussion is more or less observable throughout the book, and constitutes one of its most valuable and most distinctive features. It is never carried to excess, and never leaves the reader in doubt as to the character of the conclusions which the authors wish to enforce—giving the comfortable impression that the authors are very clear and decided in their own minds, and supplying definite reasons for almost every step that is described. The diagrams, of which there are about 150, are very clearly drawn, with reasonably fat lines instead of the eye-torturing spider-filaments which engineers most commonly affect; and the R.I.B.A. reports on reinforced concrete are included. The book seems to us, after a cursory examination, to realise very happily the intention of the authors to produce a thoroughly practical guide, not for the desk student, but for the man who would conscientiously combine theory with practice.

THE CONCRETE INSTITUTE.

A meeting of the Concrete Institute took place at Denison House, 296, Vauxhall Bridge Road, Westminster, S.W., on April 11th, Sir Henry Tanner, C.B., I.S.O., F.R.I.B.A., president, in the chair.

The following were elected members:—H. C. Forder, designer in reinforced concrete, Westminster, S.W.; P. L. Francis, designing engineer, Westminster, S.W.; H. Haughton, assistant structural engineer, Westminster, S.W.; C. B. Ife, structural engineer, Westminster, S.W.; R. G. Lovell, architect, A.R.I.B.A., M.S.A., Eastbourne; T. de Courcy Meade, M.Inst.C.E., F.S.I., etc., City Engineer, Manchester; E. Meredith, architect and surveyor, Stud.R.I.B.A., Llandrindod Wells, Wales; J. E. Mundell, architect, etc., A.R.I.B.A., F.S.I., London, E.C.; A. von Osenbruggen, designer in reinforced concrete, Westminster, S.W.; A. O. Pitt, designer in reinforced concrete, Westminster, S.W.; F. Radcliffe, engineer and manager of reinforced concrete dept., Little Royd, Huddersfield; W. Cawthorne Thorneley, designing engineer in reinforced concrete, Westminster, S.W.; B. C. Wheatcroft, manager of Armoured Tubular Flooring Co., Ltd., Westminster, S.W.

It was announced that the Council had also admitted ten students.

A paper on "The True Bending Moments of Beams" (from which extracts are given on p. 435) was read by Mr. Maurice Behar, of the Ecole des Ponts et Chaussées.

SURFACING CONCRETE
FLOORS.

BY THOMAS POTTER.

Various methods and materials have been adopted for forming finished surfaces to concrete floors, such materials being mainly of a plastic character, and consisting of fragments of granite, rag, Portland and other stones, with Portland cement. These fragments, reduced by a stone-crusher or disintegrator to pass a quarter-inch or three-eighths mesh sieve or screen, down to the size of very coarse sand, should be washed to free them from the impalpable dust that clings to all materials that have passed through a crusher, and the cement must be of the best quality. If it can be shot out of the sacks and aerated for a time, so much the better.

The proportion usually adopted is 1 part of cement of $2\frac{1}{2}$ parts of the aggregate for the best class of work; and preferably the stuff is laid in one coat, if not more than an inch in thickness, or in two coats if it is more than an inch. The concrete should be screeded straight and true (more especially if the surface material is to be only an inch thick or less), in order that it may be of uniform thickness throughout, otherwise it forms a contributory cause to the unsightly cracks so often seen in surface finishings of this character. It should be laid in alternate squares, chess-board fashion, and not more than 9 ft. each way, to wood screeds temporarily nailed to the concrete. Not less than a day—and a period of two or three days is preferable—should be allowed between the times of finishing the first-laid squares and of joining others to them, as the material expands slightly for a day or so, and then contracts to its normal size. It has been sometimes the practice to oil the edges of the finished squares, or to apply soap lather to prevent ragged appearance in case slight shrinkage occurs. This is not, however, a general practice at the present time. The material should be gently tapped with a steel trowel or wood hand-float as it is being laid, or, better still, with a small wood beater having a long handle, to enable the workman to keep his feet off the soft material. A minimum amount of water should be used for mixing, so that only a small quantity of what plasterers call "fat" may rise to the surface during tamping or beating, but which after a short time sinks or disperses in the mass.

The floor-layers, in order to avoid delay, will sometimes dust the surface with cement to absorb the excess water. This results in a film of neat cement which forms a slippery surface. A similar result may occur when too much water has been used in mixing, the effluent bringing to the surface with it some portion of the cement.

If practicable, it is better to finish the surfacing at the time that the concrete is being laid, so that perfect adhesion may take place; if the finishing is postponed, dirt may work into the crevices of the concrete, and imperfect adhesion result. This observation applies also to simple screeding with cement and sand to obtain a true surface for wood blocks, tiles, etc. Where the cost permits, thin cheap boarding is sometimes laid over the entire surface area after the screeding or floor finish has been done. This costs from 7d. to 9d. per yard, and in many cases is well worth it. Where it is not practicable to do the screeding or surface finishing

simultaneously with the concreting, the latter should be grouted with cement and sand to fill up the crevices; rather than leave them to take in dirt from workmen's boots. For general purposes, there is no object in making the surface material more than an inch thick, and even less will do, but for warehouses and similar buildings $1\frac{1}{2}$ in. to 2 in. in thickness is sometimes adopted. The ugly cracks which frequently occur in plastic floors may arise from the concrete not being laid or finished straight and true, which causes the surface material to vary in thickness and the thin places to be weaker in tension than the remaining portion; or the cracks may arise from some fault in the materials, or from insufficient mixing, or from the faulty character of the concrete beneath; and in the case last mentioned it may be years before they develop. If they are only hair cracks, or "crazing," as it is called, they probably arise from some defect in the surface material, but if larger, from shrinkage or expansion in the concrete. The durability in the latter case is not seriously affected, but the cracks are extremely unsightly, taking all kinds of irregular shapes. If they developed in straight lines, having the appearance of joints in the floor, there would not be so much objection. Where steel joists are used to support concrete floors, or are entirely or partially embedded in the concrete, it is advisable to arrange, if possible, for the joints or joining of the material to come directly over them; for when concrete shrinks, the contraction naturally takes place where it is weakest in tensile stress—that is, where it is divided partly or wholly by steel joists. Silicate of soda has been used to advantage for hardening concrete where the latter can be immersed in a bath containing five to ten per cent. of the silicate, but it does not appear to be of any advantage when added to the water used for mixing, and is therefore of little use for plastic floors. If the latter are washed with the solution when the material has set, this hastens the hardening, and allows the floors to be used somewhat sooner than otherwise.

The Choice of Aggregates.

Granite fragments are more used than any other aggregate for plastic floors. Granite was the first material to be generally used for this purpose, and answers extremely well. Occasionally it may become slippery, but this is most often occasioned by damp and dirt, as with public footpaths. Kentish rag is advocated as an aggregate by reason of being of a less slippery nature, and is used to some extent for stairs and steps, and in a general way wears equal to granite. Portland stone dries a better colour than granite or rag, but does not wear well. Corundum, the hardest material next to a diamond, is said to be non-slippery, and should withstand any amount of wear; but it is expensive. Slag from iron ore was used considerably at one time both for concrete and floor surfaces, but as it wore it was sometimes found to become more or less slippery. This drawback, however, depends a good deal on the nature of the material, some being of a glassy character. A more common objection to slag is that it contains more or less sulphur, which can only be got rid of by aeration, and may cause disintegration. This fault, however, has never come within the writer's experience. There are enormous mounds of this material, which have accumulated for years wherever there are iron mines; and as machinery has been adopted to reduce it to a con-

sistency for concrete and for surface finishing of concrete floors, there is a probability of its being used extensively in the future. But there is a great deal of difference in the suitability of slag produced by different processes in different parts of the country, and in the relative amount of sulphur contained. The general rule appears to be that for concrete purposes the amount should not exceed 0.7. Acid-process slags appear to be suitable, and basic slags unsuitable for purposes in which cement is a principal ingredient. Siliceous or flinty sand should never be added to any kind of aggregate for floor surfaces: the friction caused by walking on the latter causes abrasion and generates dust. It is a mistake to assume that because sharp flinty sand mixed with lime makes an excellent mortar, it is therefore the best material to mix with cement. The smallest particles of the aggregate should not be less than the size of a pin's head, assuming that the cement is sufficient in quantity to form a dense or homogeneous mass. Mica has come into use for pressing or embedding in cement surfaces. Its sparkling appearance is sometimes admired as a relief from the dullness common to plastic floor surfaces generally. But whatever is used as an aggregate, it is necessary that it should wear equally with the cement. A negative illustration of this proposition may be seen where soft brick steps are cemented together. The bricks wear away and the cement stands up in ridges. Again, where beach gravel or shingle is used, the cement wears, but the shingle remains; the result being rough, unpleasant walking.

The use of too much sandy element in the aggregate goes to form a cement mortar which affords less resistance to footwear than neat cement.

To obviate the hard and cold surface of floors of the kind described, sawdust, sand, and cement have been tried, but apparently with no great success; and cork paving, consisting of cement and granulated cork, has been used for some time past, principally where freedom from noise is required, but at a higher cost. Floor surfaces, in which magnesia in combination with other chemicals—a German invention—has been extensively adopted for some years past, and if properly executed is very durable. It can be done in various colours, and is easily polished. Being jointless and impermeable, it is much used in hospitals and similar buildings.

It is very necessary that the concrete on which it is laid should be quite dry, and that only Portland cement should be used as a matrix, lime being unsuitable.

Tiles, Mosaic, and Terrazza.

Tile or mosaic surfaces, terrazza, etc., are readily applied to concrete floors, but often develop cracks, probably from the same causes that affect plastic floors, and the same remedies apply—that is, performing the work in sections, or, in the case of terrazza, by the use of borders, dividing it into bays or panels. If cracks occur through expansion or contraction of the concrete beneath, there is practically no remedy. The objection to plastic floor finishing where stone or slag fragments form the aggregate, that it is cold, rendering it unsuitable for living-rooms, does not necessarily hold good with regard to sculleries, pantries, laundries, and similar places; for which, indeed, it is admirably adapted, being jointless and non-absorb-

ent, easily cleaned, and vermin-proof—points much in its favour. For warehouses and a certain class of factories and workshops it is also adapted, but not where workmen stand alongside a bench or at a vice or machine most of their time. The men complain that the floor "draws their feet," the cold surface drawing the heat therefrom and causing footache, exactly as a paved stone floor would.

Where workmen are constantly on the move, or wear heavy boots, the objection is not so apparent. Another objection to plastic floors of this description is what is called "dusting." Fine impalpable dust often occurs where the aggregate has not been thoroughly washed, or where fine sharp sand has been added, which in the friction caused by traffic cuts the material and induces abrasion. This impalpable dust is most injurious to machine bearings, more especially the delicate machines used by bookbinders, watchmakers, and others. For all such places a wood surface is to be preferred.

An excellent covering for concrete floors is linoleum, not the cheapest, about one-eighth of an inch thick, but the more substantial kind, not less than a quarter of an inch thick, and costing 2s. per superficial yard, or thereabouts.

The concrete should be screeded quite true and straight, and finished with a steel trowel to obtain a smooth surface, otherwise the solution for fixing the linoleum will not adhere. No greater thickness of cement and sand than is necessary for straightening the concrete is required. The important point is that the finished surface and the concrete are substantially dry, not merely on the surface, but throughout. If otherwise the linoleum will soon become rotten. To make sure upon this point, lay a small piece, or several pieces, of waterproof paper close to the surface for a day and night, when, if the floor is not dry, beads of water will be found on the underside. Linoleum should be fastened down at the edges and seams with the solution supplied by manufacturers for the purpose, and by workmen accustomed to the job. Linoleum shrinks if not well seasoned, and although the material may have been in stock for some considerable time, seasoning is not assured unless the rolls are opened out and the material is laid on a dry wood floor with the face side downwards for as long as circumstances permit, and, of course, in dry weather. Seasoning has much to do with its durability. I have known it to last sound, where there has been considerable wear, for more than twenty years.

On a dry cement surface, it lasts longer than on a wood floor. Cork carpet is linoleum that has not been subjected to so much pressure in the manufacture, and as a result is softer and pleasanter to walk on.

Wood in some form or other is in general use for finished surfaces of concrete floors. Wood blocks, ordinary flooring, parquetry, etc., being readily applied. Concrete floors require in their construction a large amount of water, and until this has almost entirely evaporated there is danger from expansion of the wood casing, or wood to which it is fixed acquiring dry rot and infecting the casing. Wood should never be entirely embedded in concrete, nor even partly so, unless it is exposed to a current of air, or dry rot will probably result. For this reason levelling-stumps for con-

crete on ground floors should be carefully removed and wood fillets or small joists should never be embedded in the concrete for fixing floor boards thereto.

Probably if concrete floors have been executed and protected from rainfall, and the utmost facilities afforded for drying—two or three months in summer, but longer in winter—there is not very much danger to be apprehended to the wood surface, assuming that the concrete is only of moderate thickness. The thin floated surface of the concrete should be given a week or two, or longer, to become dry before wood is fixed thereto. Where concrete is used as a base for wood surfaces on ground floors, it should be deposited on a substantial layer of dry rubble, and not on the natural soil, from which water or damp may rise. Open windows and March winds facilitate drying better and quicker than artificial heating. The surface of the concrete dries quickly under these conditions, but the appearance of dryness is rather misleading. As a matter of fact, it is impossible to seal hermetically the water in a concrete floor; it must find its way out somewhere; and if we consider the quantity required in floor construction and the slow process by which it disperses, we can understand why concrete is so long before it becomes perfectly dry.

Wood blocks are often affected by moisture in the concrete so that they rise from their beds, and, expanding, become loose, or may thrust out brick partition walls. Ordinary floor boards under similar conditions will act in the same way, or rise or turn up and form slight ridges where they join each other, although there may be some space between the boards and the concrete.

The usual way of forming a boarded surface to concrete floors is either to nail the boards to strips or fillets of wood which are nailed to the concrete floated surface, or direct thereto. In either case the floated surface must obviously be formed quite straight and true. The concrete aggregate should be coke breeze, cinders, soft brick debris, or anything of a suitable character that will enable nails to be driven therein. The proportions are 1 part of cement to 5 parts of the aggregate, floated surface, 1 part of cement to 3 or 4 parts of coarse sand, preferably coke-breeze, ashes, or brick debris screenings. Floating the surface of the concrete within a week or two of the time when the boards are to be laid may be advisable, so as not to seal the concrete with a more impermeable material (which, being of small amount, dries more rapidly) longer than necessary.

The use of wood fillets provides a space between the boards and the concrete for electric-light tubes, etc., if required; but *per contra* the hollow space becomes the receptacle for dust and dirty water from floor washings oozing through the joints of the floor-boards. To prevent the fillets should be grooved and tongued.

The floor boards should not exceed four to five inches in width. Unless the boards are secret-nailed, the many nail holes will give an unsightly appear-

ance, which, however, may be partly remedied by adopting the section shown. Water from floor-washings evaporates more rapidly from a joint of this description than when concealed in an ordinary matched or tongue-and-groove joint.

Nailing the floor-boards, square-edged, to the floated surface of the concrete (provided time has been allowed for the concrete to become dry) is, in the writer's experience, the better system of the two, as there are then no cavities in which dust and dirt may accumulate. The objection is that the boards are nearer the danger zone of water in the concrete. If means permit it is a good plan to paint the under side of the boards with red-lead paint, or a coat of bitumastic, the smell from which soon evaporates; or the entire area of the floors may be covered with cheap impermeable paper, lapping the joints. Sir Henry Tanner said, in a discussion at a meeting of the Concrete Institute, that, for the new post offices, he had tried nailing the boards direct to the concrete with no great measure of success.

The best floors, in the writer's experience, had been laid about twelve years since in a new mansion. Some were oak, secret-nailed, others North Carolina pine, square-edged, both nailed direct on the concrete, and both as perfect as at the time they were laid. The reason was obvious; the concrete had a year to allow the water contained therein to evaporate.

The surest way to set up dry rot is to cover the new wood surface of concrete floors with linoleum. It may be some time before it takes place, but it is almost sure to happen sooner or later. If the concrete is thoroughly dry, it is just possible that dry rot may not occur; but not one concrete floor in twenty is in this condition at the time it is laid.

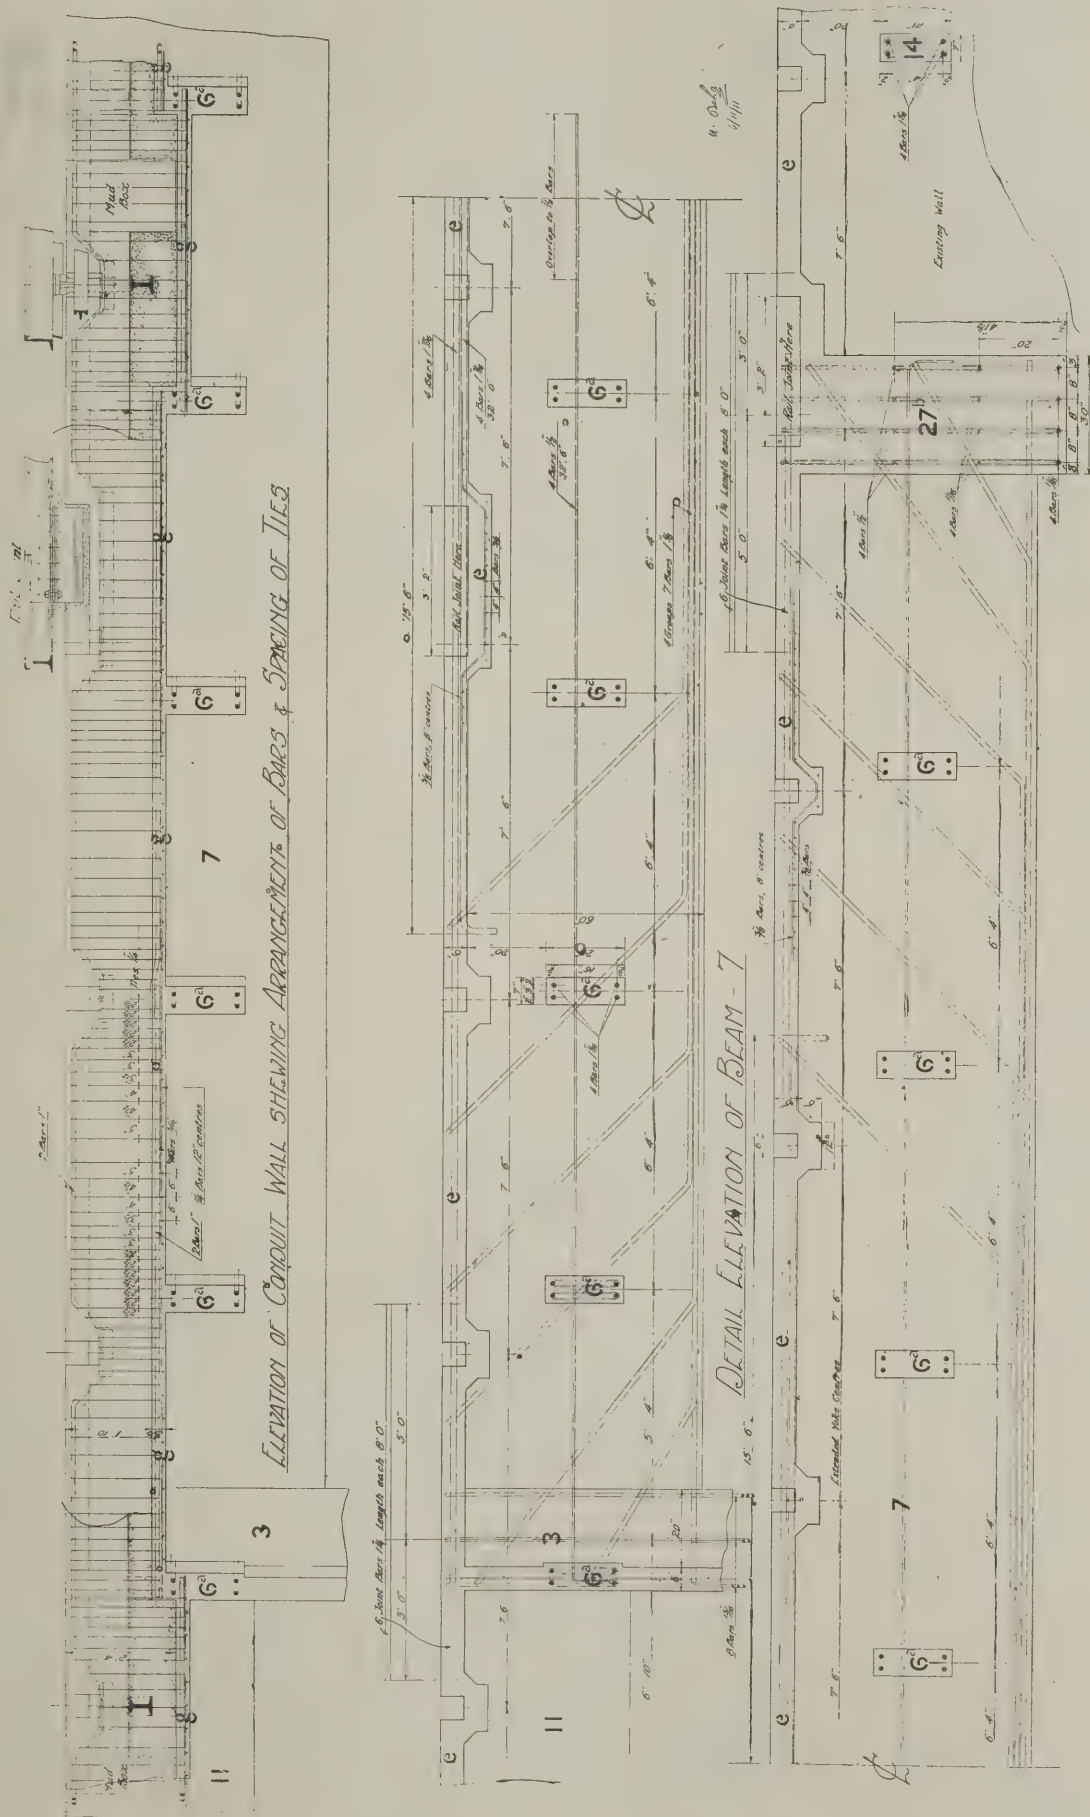

For workshops, factories, and other places where workmen are employed, maple flooring, which is harder and wears longer than deal, is the best surface material. The cost of labour in laying any kind of wood flooring direct on concrete is about double that of laying it in the ordinary way on wood joists.

Parquetry may be laid on concrete floors by gluing it to the concrete; but as the glue has to be used hot, it requires some considerable practice to do it successfully. The material used by the German specialist Eberhard was 50 lb. of glue, 20 lb. of resin, 2 lb. of boiled linseed oil, and 2 lb. of dry red-lead. It was used as hot as possible, poured on the concrete, and the blocks bedded on it. For plain work, about a superficial yard or less was done at a time, the glue chilling very rapidly. It answered very well for borders of a suite of superior bedrooms with thick linoleum laid between and carpeted in the ordinary way.

No matter what form of finished surface is adopted, the important point is that the concrete base should be sound, and in its construction means should be taken to prevent subsequent contraction or expansion. To this end it should be, if possible, executed in sections of limited area, giving time for each portion to shrink somewhat in setting, or in embedding therein tension rods, expanded metal, or wire netting, which serve to distribute the tensile stress over the entire area of the floor. Where wood is employed, the concrete and floated surface should be as dry as circumstances permit, and facility given to hasten that condition by means of open windows and doors, or artificial heat.

REINFORCED-CONCRETE BRIDGE, KING'S CROSS STATION (METROPOLITAN RAILWAY), LONDON.

REINFORCED-CONCRETE BRIDGE AT KING'S CROSS STATION (METROPOLITAN RAILWAY) IN COURSE OF CONSTRUCTION.

REINFORCED-CONCRETE BRIDGE AT KING'S CROSS STATION.

The Metropolitan Railway are at present carrying out extensive alterations and improvements at many of their stations, and in these works reinforced concrete is being extensively used.

The accompanying illustrations show the new bridge which is rapidly nearing completion at King's Cross Station. The object of this new bridge is to connect Gray's Inn Road to Pentonville Road, through the site of the old booking-office. The whole of this work is being carried out under the superintendence of Mr. W. Willox, M.Inst.C.E., engineer of the Metropolitan Railway Company.

The bridge, which is built in reinforced concrete on the Coignet system, is claimed to be the largest road bridge of this description in London. The various dimensions of the works are as follows:—There are two spans composed of straight beams, the bridge being slightly on the skew. The main span is 52 ft., and the smaller span 32 ft., giving a total length, taking into account the short end spans, of 130 ft. The width of the bridge, including the footpaths, is 60 ft.

One of the main features of this work is that it had to be constructed without interfering with the traffic of the railway below; and in order to support the wooden centering and moulds for the reinforced concrete work over the permanent ways, it was found advisable to utilise old steel trellis-work girders, which had previously been in use to support the floor of the booking-hall of the old station.

The roadway, which has been calculated for a uniformly distributed load of two cwt. per sq. ft., and also for two moving point loads of eight tons, situated at 6 ft. centres, has been designed in such a manner as to accommodate two lines of double-deck electric tramways of the usual London County Council type. Accommodation has been provided between the reinforced concrete beams for the special cast-iron yokes and ducts for

the supporting of the rails and the transmission of the electric power.

The details of the reinforcement are in accordance with the Coignet system for the construction of straight beams. The main bars vary in diameter between $\frac{1}{2}$ in. and $1\frac{1}{4}$ in., and are of mild steel with a round section. The tension and compression reinforcing bars are connected together by means of stirrups, also made with round bars of small diameter. These vertical stirrups are ar-

ranged in such a manner as to take up the shearing stresses, and also in order to form a mechanical connection between the main reinforcement of the beams.

The slabs are composed of bars varying between $\frac{3}{8}$ in. and $\frac{5}{8}$ in. in diameter and arranged to form a meshwork. It is anticipated that this important bridge will be open to traffic early in the summer. We understand that the design of this bridge was obtained by Messrs. Edmond Coignet, Ltd., of 20,

REINFORCED-CONCRETE BRIDGE, KING'S CROSS, LONDON: VIEW SHOWING CONDUITS FOR TRAMWAYS.

Victoria Street, S.W., in open competition. The work has been carried out by Messrs. W. King and Son, contractors, of London, licensees of the Coignet system. [We are desirous to state that the name of another firm of contractors (p. 401 of last week's issue) was given in error.]

With respect to the article on the Metropolitan Railway's new offices published in our last issue we have to point out that the descriptive notes beneath the illustration on page 403 do not refer to the building in Marylebone Road, but to the elevation of the new offices reproduced on the preceding page. The building shown on page 403 is not to be constructed entirely in reinforced concrete; Messrs. Drew-Bear, Perks and Co., Ltd., inform us that they have been entrusted with the steelwork contract of this building up to the first floor level.

THE TRUE BENDING MOMENTS OF BEAMS WITH VARIOUS DEGREES OF FIXITY.*

BY MAURICE BEHAR, CIVIL ENGINEER (ECOLE DES PONTS ET CHAUSSÉES).

The object of this paper was to discuss certain principles and formulæ for reinforced concrete work which have been the subject of controversy, and also to show, by means of examples, the excessive increase in the weight of the steel bars in beams and posts in reinforced concrete, due to the application of these methods.

As to beams, the author said, almost all the engineers specialising in reinforced concrete calculate these elements by applying the usual laws of mechanics, or, in other words, the laws governing the strength of materials. Nevertheless, for the main beams and secondary beams fixed at their extremities to other members in reinforced concrete, such as walls, posts, or other beams, the specialist engineers usually admit that a certain amount of fixity takes place at these points of junction, and concerning this it is usual to make certain assumptions.

*Extracts from a paper read before the Concrete Institute on April 16th.

Some engineers consider that the fixation is partial on the support, and has for its value $\frac{WL}{24}$. In this case they calculate their moment at the middle of the beam, sufficiently strong to resist a bending moment of $\frac{WL}{12}$, which is the corresponding moment to the one stated above.

Other engineers, and we think they are in the majority, consider that the bending moment should be $\frac{WL}{10}$ in the middle of the beam, and in this case they provide at the points of support a section of steel capable of resisting a corresponding moment of $\frac{WL}{40}$.

Again, other specialists consider that reinforced concrete beams extending over several spans must be considered as continuous, and they apply to the calculation of these beams the usual rules governing continuity.

In addition to the three above-mentioned methods of calculating a beam in reinforced concrete fixed upon its two points of support, it is now my intention to consider the method which has been put forward for official sanction, and which would have the effect of stipulating a bending moment of $\frac{WL}{12}$ in the middle of the beam and $-\frac{WL}{12}$ at the points of support.

Of these four methods of calculation, let us consider the question of which one produces the maximum of safety in the construction.

(1) Let us assume that the bending moment in the middle is $\frac{WL}{12}$, and

that the corresponding moment at the points of support is $\frac{WL}{24}$. It may happen that on account of the continuity of two consecutive beams and the distribution of the loads on the spans, that the moment at the point of support becomes greater than the one provided for. In this case fissures will occur at this point.

Let us now assume by exaggeration that these fissures render the points of support absolutely free. The middle of the beam will then support a bending moment equal to $\frac{WL}{8}$, but as the beam has been calculated for a bending moment in the middle of $\frac{WL}{12}$, the factor of safety will become—

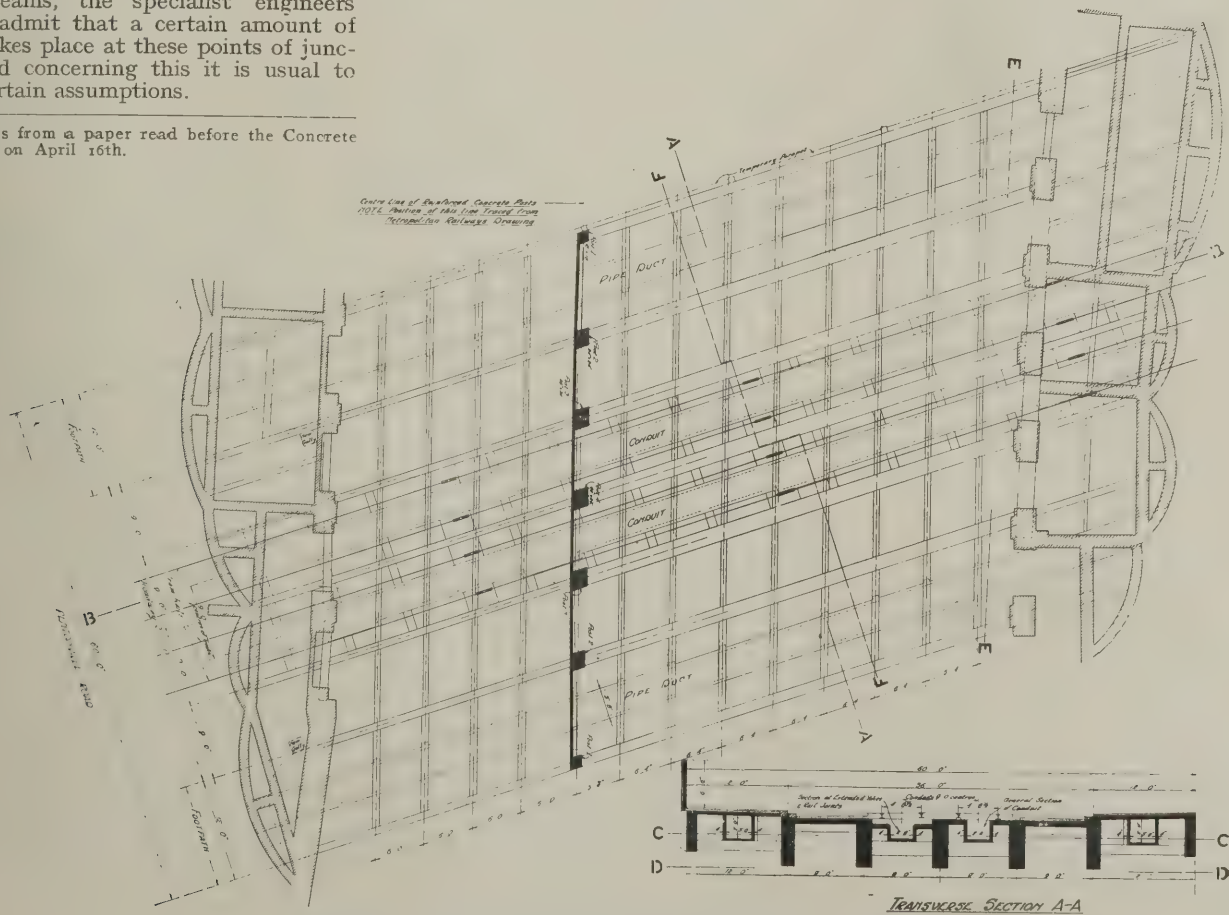

$4 \times \frac{8}{12} = 2.666$ instead of 4.

The beam will not collapse on this account, inasmuch as the concrete in the lower part of the beam situated underneath the neutral axis is working in extension, which has not been taken into account in the calculations.

(2) Let us now assume that the bending moment in the middle is $\frac{WL}{10}$ and the corresponding moment at the supports is equal to $\frac{WL}{40}$. The method of reasoning is the same as for the above, except that in the case of the transformation of the point of support into a free support the factor of safety becomes

$4 \times \frac{8}{10} = 3.2$ instead of 4.

(3) Let us now consider the continuous beams. In this case the moments at the supports are generally greater than $\frac{WL}{12}$.

REINFORCED-CONCRETE BRIDGE, KING'S CROSS, LONDON.

Concerning the moments in the middle of the spans, they will often be much less than $\frac{WL}{12}$. We must remember, however, that although in structural steelwork it is possible to obtain perfect continuity between two consecutive spans, it is not so with reinforced concrete, where the continuity depends upon the adherence of the concrete to the bars provided in the upper portion of the beam at the points of support.

I am of opinion that the method of constructing consecutive beams in reinforced concrete does not ensure such perfect continuity as that which may be obtained in consecutive metallic girders. If owing to this lack of solidarity between two consecutive spans, or if owing to bad construction the point of support should give way and become transformed into a free support, then the middle of the beam, which may in certain cases have been calculated with a moment less than $\frac{WL}{12}$, will have a factor of safety less than 2.66, and in certain cases even less than 2. It is obvious that the construction in this case becomes endangered, and the danger is all the greater because if one of the beams gives way the others will give way in turn, on account of the fact that the continuity upon which we relied will have disappeared owing to the failure of the first element.

It is for this reason that in steel construction, when there are several continuous spans, it is usual to divide these into a series of portions of three or four consecutive continuous spans, each portion being separated by free supports.

(4) If we consider $\frac{WL}{12}$ in the middle and $-\frac{WL}{12}$ at the points of support, this case certainly has the effect of producing a greater safety than those above mentioned. In the middle there is the same drawback as in the first case, but not the one due to continuity. At the supports, however, this case is weaker than the case of continuity, although it has very nearly the same value. On the other hand, the latter method obliges the engineer to provide, as in the case of continuity, in the bottom compressed portion of the beam, and at the points of support, a considerable section of steel, and this section will be all the greater at these two points, on account of the fact that, if this principle is admitted in the Official Regulations, the section of steel required will have to be calculated by applying a stress in the steel equal to fifteen times the stress of the concrete, taken at the axis of the reinforcement employed.

Now, as a matter of fact, a large number of examples of principal beams and secondary beams which I have calculated with $\frac{WL}{12}$ at the supports have proved to me that the working stress of the steel in compression is always below 8,000 lb. per sq. in., and that in secondary beams this stress rarely attains 6,000 lb. per sq. in. The result is that one is often obliged to provide such a considerable number of steel bars, that it is materially impossible to place them in the small compressed area of the concrete, in the bottom of the beam.

A close examination of the four methods of calculation mentioned above has led me to conclude that as far as stability is concerned, the moment of $\frac{WL}{12}$ in the middle and at the supports gives a greater security. $-\frac{WL}{24}$ or $-\frac{WL}{40}$ at the supports

and their corresponding values of $\frac{WL}{12}$ or $\frac{WL}{10}$ in the middle would never actually cause the collapse of a beam. The most that could happen in such a case would be, that the floor slab over the beams would show fissures, whereas, if we consider the case of continuity, we find that this may prove dangerous if the workmanship is bad or the materials are unsuitable.

From an economical point of view, the semi-fixation with moments of $-\frac{WL}{24}$ at the support and $\frac{WL}{12}$ at the middle, requires about the same amount of steel as the partial fixation with moments of $-\frac{WL}{40}$ at the supports and $\frac{WL}{10}$ at the middle.

Concerning $-\frac{WL}{12}$ at the supports and $\frac{WL}{12}$ in the middle, when it is possible to actually construct the beam by accommodating the amount of steel required, I have found that these values bring about an increase 40 to 50 per cent. greater than required in the case of semi or partial fixation mentioned above, and that in certain cases the excess of steel may be as much as 100 per cent.

Concerning the case of continuity, if we are obliged to provide in the lower portion of the beams the necessary section of steel to take up the compression at the points of support, and if we put aside the method which consists of reinforcing this portion by means of spirals, the weight of the bars would be less than that due to $-\frac{WL}{12}$ at the supports and in the middle, but the weight of steel would be superior to that produced by the formula of semi or partial fixation.

I understand that for various reasons the method of reinforcing the concrete in the beams by means of spirals would not be considered or authorised in the new Regulations, and it is doubtful whether this particular method could meet the difficulty in an economical manner. If, however, the new Regulations were to allow the use of spirals, to increase the compression of beams, and if it was found that this was the only possible way of solving the difficulty of the compression, then it is obvious that the Regulations would have the effect of favouring, to the exclusion of all others, one particular method only for which a patent has been obtained, thereby creating a monopoly.

It is therefore absolutely necessary that the proposed Official Regulations should not have the effect of obliging engineers to calculate beams fixed at both extremities with a bending moment of $-\frac{WL}{12}$ at the supports and $\frac{WL}{12}$ at the middle, and I sincerely trust that the authorities who are at present drafting out new Regulations will simply stipulate the application of the usual laws of mechanics for the determination of the dimensions of beams in reinforced concrete; and also hope that the case of semi-fixed beams, which is in no way empirical, and which is absolutely in conformity with the laws of mechanics, shall be considered and shall find its proper place in the new rules.

M. Behar then proceeded to deal with compression in the upper portion of the beams and in the middle of the span; lintels or beams without slabs; and posts or pillars in reinforced concrete. Special

attention was given also to the question of ascertaining the position of the neutral axis in various cases. The paper was mostly of a mathematical character, and had for its principal object the eliciting of views of all those concerned in the design of reinforced concrete in a discussion upon all the subjects dealt with in the paper.

In the discussion which followed, the following gentlemen took part:—Professor Henry Adams, M.Inst.C.E., M.C.I., R. W. Vawdrey, B.A., Assoc.M.Inst.C.E., M.C.I., Ewart S. Andrews, B.Sc. (Eng.), M.C.I., Morgan E. Yeatman, M.A., M.Am.Sec.C.E., M.C.I., D. Weoster Robertson, M.C.I., Herbert E. Steinberg, Assoc.M.Inst.C.E., M.C.I., E. Fiander Etchells, F.Phys.Soc., M.Math.A., A.M.I.Mech.E., M.C.I., Sir Henry Tanner, C.B., I.S.O., F.R.I.B.A., Pres.C.I.

A REINFORCED-CONCRETE LIGHTHOUSE.

A reinforced-concrete lighthouse on a concrete crib foundation has been recently completed at Huntington Bay, N.Y. It is of the ordinary pilaster construction, with intermediate wall slabs, and is covered with a flat roof, around which is placed a concrete parapet wall. The light tower, although an integral part of the building, is built monolithically, and has a square exterior measuring 10 ft. on a side, with a circular interior 8 ft. 4 in. in diameter. Considerable attention was paid to the surfacing of the concrete. The pilasters were washed and polished, and in the slabs between them the aggregate was exposed first by a pneumatic tool, then by a bush hammer, and subsequently washed with muriatic acid. A 1:2:4 concrete mixture was used on the work. No provision was made for waterproofing the walls at the time the concrete was put in, but as they were found to be pervious to the driving rains and the spray of severe storms they were treated with a waterproofing compound.

DESCARTES ON TOWN PLANNING.

There is seldom so much perfection in works composed of many separate parts, upon which different hands had been employed, as in those completed by a single master. Thus it is observable that the buildings which a single architect has planned and executed are generally more elegant and commodious than those which several have attempted to improve, by making old walls serve for purposes for which they were not originally built. Thus also, those ancient cities which, from being at first only villages, have become, in course of time, large towns, are usually but ill laid out compared with the regularly constructed towns which a professional architect has freely planned on an open plain; so that although the several buildings of the former may often equal or surpass in beauty those of the latter, yet when one observes their indiscriminate juxtaposition, there a large one and here a small, and the consequent crookedness and irregularity of the streets, one is disposed to allege that chance rather than any human will guided by reason must have led to such an arrangement. And if we consider that nevertheless there have been at all times certain officers whose duty it was to see that private buildings contributed to public ornament, the difficulty of reaching high perfection with but the materials of others to operate on will be readily acknowledged.—*Rene Descartes: "Discourse on Method"* (1637).

REINFORCED-CONCRETE CHIMNEY STACKS.

A reinforced-concrete chimney stack, recently erected near Drury Lane, London, W.C., by Messrs. G. Trollope and Sons and Colls and Sons, Ltd., is 144 ft. 9 in. high; and as the volume of gases to be carried up is comparatively small, an inside diameter of 2 ft. 6 in. was considered to be sufficient. Mr. Oscar Faber, B.Sc., A.M.I.C.E., the chief engineer to the contractors, believes that it will be of interest here to explain the considerations which led to the erection of the chimney in reinforced concrete, since, though the advantages of this material are frequently lauded in a general way, the particular chimney under consideration could hardly have been built in any other material. The chimney, if built of brick, would have to comply with the London Building Act of 1894, Section 65, which enacts, *inter alia*—

(1) Every shaft shall . . . taper gradually from the base to the top of the shaft at the rate of at least $2\frac{1}{2}$ in. in 10 ft. of height.

(2) The thickness of brickwork at the

top of the shaft . . . shall be at least $8\frac{1}{2}$ in., and shall be increased at least one half-brick for every 20 ft. measured downwards.

(6) The width of the base of the shaft . . . shall be at least . . . if the same is round . . . one-twelfth of the height.

(7) Any fire-bricks built inside the lower portion of the shaft shall be provided as additional to, and independent of, the thickness of brickwork prescribed by those rules, and shall not be bonded therewith.

It will be seen from these that the minimum dimensions permissible for the brick-shaft would be:—

Outside diameter at top	..	4 ft.
base	..	12 ft.
Wall thickness at top	..	9 in.
base	..	3 ft.

Allowing a wind pressure of 25 lb. per sq. ft. on the projected area of the chimney (this pressure being assumed to include the reduction factor for circular cross-section), it will be found that the overturning moment

$$M = 1,748,000 \text{ ft.-lbs.},$$

and the weight

$$W = 638,000 \text{ lb.}$$

The Completed Chimney.

Whence

$$\text{the eccentricity } e = 2.74 \text{ ft.}$$

If the brickwork were capable of resisting tension, the maximum compressive stress would be

$$C = \frac{638,000}{84.75} + \frac{1,748,000}{158.8} \\ = 7530 + 11,000 = 18,530 \text{ lb./ft.}^2, \\ \text{or } 128 \text{ lb./in.}^2.$$

This figure would only be justified if the brickwork were capable of resisting a tensile stress of 3470 lb./ft.^2 or 24.1 lb./in.^2 .

The exact calculation of the maximum pressure when the tensile strength is ignored is not a simple matter, although it may be determined in the same manner as that advocated for reinforced-concrete chimneys in the article by Messrs. Taylor, Glenday, and the writer, which appeared in "Engineering," March 13th, 1908. (An illustrated article on the chimney now under notice was given in the issue of our contemporary for December 22nd, 1911.) It is obvious, however, that it would exceed $128 \text{ lb. per sq. in.}$, whereas

DETAILS OF FIRE-BRICKS

REINFORCED-CONCRETE CHIMNEY, DRURY LANE, LONDON.

125 lb. per sq. in. is the limiting stress allowed by the London County Council for hard brick in cement mortar. It will be seen, therefore, that an outside diameter of 12 ft. is not only the least permissible by the London Building Act, but is also the least which a prudent engineer would care to erect. This size of chimney, though small in comparison to its height, is, however, considerably greater than could be erected at Short's Gardens, owing to great scarcity of room. The alternatives were therefore reduced to a self-supporting chimney of steel or reinforced concrete. The first of these could not be passed as a permanent structure by the London County Council, owing to the corrosion of the steelwork, and only a reinforced-concrete

chimney would meet the case. When it is shown that the diameter at the base was kept down to 5 ft., it will be seen how effective was the substitution of reinforced concrete for brick. The lower portion of the chimney, up to flue entrance, is 1 ft. 3 in. thick, and above that 6 in. thick. Above the flue entrance a lining of firebrick 5 in. thick is provided, with an air-space 4 in. thick between it and the outside shell. Vent-holes are left near the flue entrance, through which a current of air is induced in the air-space between the liner and the outer shell. Experience with several chimneys of this type has shown that the concrete shell is liable to crack badly under the heat of the chimney, and this fact has no

doubt hindered to no small degree the employment of reinforced concrete for this purpose. Some theoretical calculations of temperature stresses led Mr. Faber to a system of construction in which timber rings are embedded at intervals on the inside face of the concrete shell, which practically reduces to zero the stresses due to expansion. This system of construction, which is patented by Mr. Faber, was adopted by the Associated Portland Cement Manufacturers in a chimney built by them at their works at Burham, on the Medway. This chimney has now been in use several months, and is quite free from any cracks due to temperature stresses.

The History of Lincoln's Inn Fields.

THE third volume of the "Survey of London" has just been issued, under rather peculiar circumstances. It was in January, 1906, that the London County Council directed the General Purposes Committee to report what course the Council should adopt in case of the contemplated destruction of any building of architectural or historical interest. Ultimately it was resolved that the Committee for the Survey of the Memorials of Greater London, having already made a register of buildings in the East End of London, should be requested to continue its work, and that the Council should print portions of the Register from time to time; and accordingly the Survey furnished the materials for Volume I. of the Register, dealing with the Parish of Bromley-by-Bow. An agreement was come to with the Survey Committee by which the Council bore the expense of printing, leaving the actual documents in the hands of the Survey Committee and supplying them with 500 copies of the volume for their members. This arrangement being considered unsatisfactory (we are not notified why), the Survey Committee published Volume II. (Parish of Chelsea) at its own cost. But a large amount of material having been collected, the Council, "having regard to the rapidly changing character of London," desired the work to be continued without further delay, and eventually entered into an agreement for five years with the Survey Committee, providing that the materials collected should be published from time to time in the joint names of the Council and the Survey Committee, the Council retaining financial control, bearing the cost of production, and taking the proceeds of sale, and presenting the Survey Committee with copies for its subscribers. Briefly, the Survey Committee does the work and the County Council takes the risks. The outcome of this arrangement is Volume II. of the "Survey of London," the title standing thus:—
"Survey of London: issued by the joint publishing committee representing the London County Council and the Committee for the Survey of the Memorials of Greater London. Under the general editorship of Sir Laurence Gomme (for the Council) and Philip Norman (for the Survey Committee), Vol. II. The Parish of St. Giles-in-the Fields (Part I.), Lincoln's Inn Fields."

It was rightly judged that so much historical and architectural interest attached to Lincoln's Inn Fields that it merited a volume to itself, the remainder of the parish to be dealt with in a succeeding volume.

We are given the map of Lincoln's Inn Fields as they existed in 1592, with the present streets and buildings indicated by dotted lines over them. The site then consisted mainly of a large field called Cup Field, about the same size as the present square, with a ditch running north and south through the centre of the field; and Purse Field, a long narrow field westward of it, running north and south, the western boundary of which coincides with the eastern margin of Kingsway; and on part of Purse Field stand the houses on the west side of the square. Though it is evident enough that the Fields in the sixteenth and early seventeenth centuries were little better than waste land with a great deal of rubbish dumped on to it, the Society of Lincoln's Inn seem to have attached much

importance to this open space, and the story of their repeated efforts and petitions to prevent any building on it forms rather amusing reading. They did, however, in 1617, betray a desire to have the ground improved in appearance. The land to the north of Moorgate, outside the City, had recently been reclaimed from its marshy condition, and drained and laid out in walks as a place of recreation. This seems to have roused the emulation of the Society, who petitioned the King that "the feildes commonly called Lincolnes Inne Feildes, being parcell of his Ma^{ties} inheritance, might for their generall Commoditie and health be converted into walks after the same manner as Morefeildes are now made to the greate pleasure and benefite of that City"; a petition which the King did not only "take in very gracious and acceptable parte," but even voluntarily enquired, a year later, after the success of the scheme. A commission was in fact appointed to lay out Lincoln's Inn Fields in "faire and goodlye walkes" which would be not only a means of health and recreation to the inhabitants of the neighbourhood, but "for the sight and delight of Embassadors and Strangers coming to our Court and Cittie"; and on this commission sat no less a person than Inigo Jones; but it led to nothing at the time, and apparently it was not until the square had been built round in the latter part of the seventeenth century that any laying out of the land seems to have been done. An engraving is given of a picture at Wilton House, of the probable date of 1683, showing the square with houses on three sides (whether actually built or only as proposed seems doubtful), and the open space with railed diagonal walks. There is not a tree shown; these must have all been grown or transplanted at a later period. Dated 1699 is a bird's-eye view of a rather good design by one Cavendish Weedon for laying out the square with a temple in the middle (for which Wren made a design), and wide

NOS. 59 AND 60, LINCOLN'S INN FIELDS.

CHIMNEYPiece IN FRONT ROOM OF FIRST FLOOR
NO. 35, LINCOLN'S INN FIELDS.

cross-walks at right angles, with circular bays with a statue in the centre of each; buildings are shown on two sides only; but in spite of such proposals it seems that as late as 1735 the square is described in an Act as waste and in great disorder, "a receptacle for rubbish, dirt, and nastiness of all sorts," and a dangerous place to walk through at night. In this year the inhabitants of the square obtained an Act to enable them to rate themselves for the improvement of the square, and it was decided to lay it out with grass and gravel walks, with iron palisades on a stone plinth, and a circular basin of water in the centre. This basin seems to have been a trouble to the Trustees, and was filled up in 1790, "after much debate and opposition among the inhabitants." The garden was rearranged on its present plan early in the nineteenth century.

With the voluminous history that is given of the families and eminent persons who have been connected with the square, interesting as they are, we cannot concern ourselves here; our business is with the architectural relics. It may be noted that there has more than once been a proposal to build a church in the centre of the square; Colin Campbell made a design for one in 1712, and applications with the same object were made in 1819 and 1824. Subsequently a suggestion was made that the Courts of Justice should be erected in the centre of the square, and Sir Charles Barry actually made a design for them on this site. It is fortunate that this proposal was abandoned; but a fine church in the centre of the square, as at The Boltons, might have done very well, if the square had maintained its residential character. But residential London was steadily moving westward, and the square, for the most part, fell from its high estate in this respect, and the once desirable residences were mostly cut up into offices. It was this change which led to the square garden becoming deserted and useless, and suggested to the County Council their wise and beneficent action in securing its use for the public.

As to whether the dignified-looking front to Nos. 59 and 60, of which we give an illustration, is really due to Inigo Jones, there seems to be no positive evidence; but it is not unlike his work. Considering that he was on the original Commission for laying out the square (though he is not known to have made any design for that), it is exceedingly likely that he would have been called on to design some of the houses; and at all events the two grand brick gate-piers, which are really the most important outdoor architectural relics to be seen in the square, bear the manifest impress of his hand. Among the other exterior architecture of the square, the portico of the College of Surgeons has rather a curious history. It was erected by Dance, the younger, in 1813, with unfluted

columns. When the extension of the premises became necessary in 1834, Barry was called in to erect a new and larger building, but Dance's portico was re-erected; only, as the axis of the building had to be altered, this was effected by removing two of the columns from the west end of the portico and re-erecting them at the east end; and under Barry's directions the columns were fluted, which undoubtedly improves their appearance. An interesting sketch by Scharf, forming Plate 44 in the book shows the building operations in progress, and five of Dance's columns, with part of their entablature, standing in front of the work. Probably few who pass that portico know anything of its curious history. Another interesting elevation is the one which Soane made for his own house, No. 13, now the Soane Museum, with an interior full of interest both in regard to its plan and design and its contents, known to but a small section of the inhabitants of London. The front is a very interesting and original piece of architectural design based on Greek ideas, and it looks, from the point of view of the present day, remarkably modern in style; the details might have belonged to a building erected within the present decade, except for the two late Gothic capitals, or models of capitals, which form rather awkward-looking excrescences on two of the piers.

But the interiors which are now cut up into offices contain a wealth of charming and interesting detail. Some of the wooden staircases are admirable, especially that in Nos. 33 and 34, where the usual spirally-turned balusters are interrupted at intervals by a miniature fluted column and capital, above which the handrail is raised by a slight ramp, to give additional point to the incident. The plans of some of them, and the ingenious way in which the elliptical staircases are worked in, deserve attention. On the staircase of No. 35 is a fine iron balustrade, and on the first-floor landing a still finer open-work panel, of which we give an illustration; this, as the editor remarks, recalls Jean Tijou's ironwork. But No. 35 is full of fine work of different kinds; from its illustrations we take also that of the very fine and unusual design of a chimneypiece in the front room on the first floor. The door-case of the same room, with a pediment and Ionic columns, is also an excellent piece of work of its kind. On the ground floor of No. 59 is a remarkably fine alcove, under a segmental arch panelled on the soffit, and springing from an entablature carried by Ionic columns on each side.

NEWCASTLE HOUSE, LINCOLN'S INN FIELDS: THE HALL.

WROUGHT-IRON PANEL ON LANDING, NO. 35, LINCOLN'S INN FIELDS.

It seems quite a pity that all this beautiful interior detail, once the pride of the owners, and the objects of admiration, no doubt, of their visitors, should now be buried in offices and other rooms to which there is, in the stock phrase, no admittance except on business. A publication like the one under review is of value merely in making such work known by illustrations, independently of the amount of interesting history contained in its text. We hope the joint publication will go on successfully and give us many more such volumes. We shall look with interest to the promised fourth volume, dealing with the remainder of the Parish of St. Giles-in-the-Fields, including Flitcroft's celebrated church.

Regent's Park in the Making.

AMONG the interesting quotations which the "Times" gives us of events 100 years ago, a recent one gave some account of the making of Regent's Park, which enabled us to see the scheme as it was seen by the public at the time it was undertaken. The grand entrance to the new park is, we are told, from Portland Place, "which is now extending towards the south on the site of the recently demolished Foley House" (where the Langham Hotel now stands); so that the conclusion is that Portland Place was commenced at the north, and not, as would have seemed more natural, at the south end. The liberal width of the street, so different in this respect from most London streets of the period, or even of the present day, is owing to the fact that the owner of the mansion which then stood on the Langham Hotel site had a clause in his lease covenanting that no houses were to be built to the north of his house, to destroy his country view; so, to fulfil the letter of the law, the street had to be made the same width as the mansion, with a result very satisfactory to us at the

present day; one can only wish that more London streets had been laid out under such conditions. After the mention of Foley House, there follows a complaint that "the new buildings here do not appear to be constructing with any suitable regard to the elegant uniformity of Portland Place." It is not easy to understand what "here" means, and what were the buildings which were unworthy of the "elegant uniformity" of the new street. The account goes on to state that "at the north end of Portland Place a circus is forming, surrounded by trees, across the centre of which runs the new road," so that the road was originally to have run straight on through what is now the garden in the middle of the crescent. Nothing is said of houses in the crescent, which, apparently, was at first only an ornamental laying out of the plantations. The large lake does not seem to have been contemplated in the first instance, as it is only said that advantage will be taken of the means the ground affords for increasing the picturesque beauties of the spot, "by the formation of two or three sheets of water in the level situations." The account, while generally praising the work that is in progress, concludes by admitting that "not a few will regret the loss of those open and verdant fields which formed one of the most airy and pleasant resorts of the pedestrians of the metropolis." But a park in process of formation is never a very encouraging sight; it needs half a century or so to settle down.

Municipal Improvements in Paris.

IT is rather amusing to read that when the Paris Municipal Council held its final meeting before the elections, the President (M. Roussel), in reviewing the work which was proposed to be done with the £36,000 voted for municipal improvements, spoke of "a great scheme in the air for laying out spacious boulevards which would run right

NEWCASTLE HOUSE, NOS. 66 AND 67, LINCOLN'S INN FIELDS, LONDON.

round the city, on the lines of the present fortifications and moats, now antiquated, dilapidated, and useless." Why, the scheme has been "in the air"—been talked of and promised, for at least thirty years back! Definite proposals have been made for carrying it out, time and again, which have all fallen through because no capital was forthcoming to take it up; and now it comes up again in the newspapers as a new idea. No doubt it is a scheme which might have very fine results, but the only chance, apparently, of seeing it carried out is that the Paris municipality should itself take it up and find the necessary capital. If that is part of the work on which the 36 millions is to be expended, it will no doubt be a great Paris improvement, and it may in the long run be a paying one; but it will make a considerable hole in the 36 millions. It is satisfactory to find that the improvement of the Paris water supply enters into the municipal schemes. The water supply has been the weak point in Paris for many years, both in respect of quantity and quality; there has never been enough water, and what there was has never been really satisfactory as drinking water. We remember a year when the hydraulic lifts in the large hotels could hardly be worked owing to want of water. There has been scheme after scheme for

enlarging the supply, but the demand seems always to exceed the supply. It is to be hoped that some final settlement of the matter will now be arrived at.

The Architecture of the New Delhi.

WE see that the question is already being raised in Anglo-Indian circles, What is to be the style of the new Government buildings and the new town (for it will be practically a new town) of Delhi? It is one of the largest architectural questions that could be raised, and one of the most difficult to answer. The Romans, in a similar case, would at all events have had no doubt whatever. For them Rome was the one important entity in the world; she was the mistress of the world, she was to say how things were to be done. Wherever the Roman eagles went, there followed in their train the Roman triumphal arch, the Roman forum, the Roman theatre, and the Roman aqueduct. The latter was an unmixed blessing to the conquered land; it did not pretend to be architecture, it was a useful engineering construction only, bringing an adequate water supply. For the rest, if the usual type of Roman architecture was good enough for the

CAMPANILE, VENICE.

conquerors," it was "believed to be certainly good enough for the conquered. They should be taught what architecture meant.

In the earlier days of our sway in India we pursued nearly the same course, not from any particular interest in architecture, but rather the reverse, from absolute indifference. The kind of men who had to battle with the difficulties and dangers of early English rule in India were not the people to trouble their heads much about art; they had more serious business in hand. When new buildings were wanted they were wanted for practical purposes; Government and business buildings were built in much the same manner as they would have been built in London, and Calcutta Cathedral was erected in Batty Langley Gothic. Now we have become aware that we have become rulers of a country which possesses a great deal of beautiful art quite different from our own, and the question is raised, If we build a new city there, for Western rulers among an Eastern people, is it to be Western or Eastern architecture? It is rather important, for we ought to do ourselves architectural credit with our new city.

It cannot be settled merely on æsthetic grounds, for the climate is an element in the choice. Were the climate and the light the same as in England, the Roman principle would really be the best; to put up our best architecture at Delhi as we should put it up in London. That would be the best architectural symbol that we are the rulers, and therefore bring our own architecture with us, as the Romans did. But the climate will not allow that. We have to keep the tropical heat off the walls, and to have verandahs or loggias for shelter from the sun, and smaller windows than in England, where we are glad to have all the light we can get. And mouldings and sculpture which have sufficient shadow and relief to be effective in a northern climate would seem far too pronounced in effect under an Indian sun. The simple transplantation of European architecture to Delhi obviously will not do.

There is the opposite course, of completely adopting an indigenous style; accepting, for instance, the school of architecture left as a legacy by the great Indo-Saracenic builders of the sixteenth and seventeenth centuries. There is something to be said for this, in view of the fact that we should have to employ native labour. There is a kind of precedent for this in the architecture carried out in Sicily under the brief rule there of the Normans. They obviously employed the Saracenic artists who had already had a footing on the island, and we see buildings which we know were built under Norman rule, but which are all but Saracenic in general character. But except in regard to some beautiful decorative detail, the result is not very satisfactory; there is an uncertainty of motive and a rather barbaric jumbling of different types of detail in most of these Norman-Saracenic buildings. The Normans obviously did not bring their own architects with them. We certainly wish to bring ours, or some of them, to Delhi; in fact, there will be great searchings of heart if we do not. And it seems not only suitable, but desirable, that new Delhi should bear the architectural impress of being a product of British rule.

The true solution of the problem seems to be this: the architecture should be designed by English architects, and should be founded in its main lines on the English public architecture of the present day; which may be taken to mean, generally, free Classic style; but modified in planning, details, and decoration to suit the climate, and to some extent to recognise Oriental associations. That would mean, in the main lines of the architecture, cornices of considerable projection, to keep the sun off the walls, and the introduction of open loggias or verandahs as far as they can be made to fall in with the plan. And as far as detail is concerned, it would mean less dependence upon mouldings, the effect of which is apt to be exaggerated in strong sunlight, and more dependence on surface decoration in colour. In the natural course of architectural development strong sunlight has always seemed as it were to bring out colour in a national architecture. And in regard to mouldings, we see the effect of the difference between southern and northern climate exactly expressed in the difference between Greek and Gothic mouldings. The deep rolls and deep hollows of Gothic mouldings are exactly

what were wanted for effect in the climate in which they were developed; in the climate of Greece they would never have been introduced, for they would have been felt to be too emphatic. We should study for effect in new Delhi, therefore, by delicate mouldings and a considerable use of colour in inlaid materials. On these principles something like a new style might be evolved, based on European Renaissance architecture in its general lines; based on Oriental style in its detail.

On such lines it would be possible to produce some fine results with the modern Anglo-Indian architecture for which there seems likely to be new opportunity of development.

Roads and Town Planning.

THE question of economy in road-making, in the laying-out of new residential estates, was a prominent one in the recent Housing Conference, and is rather a new practical point in connection with the subject. Mr. Jeffes, the surveyor to the Malden and Combe Urban District Council, read a paper on the subject, contending that under present by-laws roads were often made wider than was really necessary for what might be called side roads, merely for access to houses, and on which the traffic only consisted in the supply of goods to the houses. In a 40 ft. street the carriage-way was usually 24 ft., with an 8 ft. footway on each side. He said that the lay-out of these streets allowed of little variation to meet special circumstances, and imposed the same requirement as to width of carriage-way in streets taking a considerable amount of traffic as for streets where the traffic was light. He thought it was possible, in the case of such streets, to allow of a reduction in the width of the carriage-way, giving more space for footway and for the planting of trees; also that the widths of the streets between the fences might be reduced, thus allowing more variation, and giving to the houses some of the land at present used as a roadway. This is a point that certainly deserves consideration. There is no doubt that a roadway which is wider than is really necessary for the traffic to be counted upon means so much wasted space, besides the cost of making the roadway. The question whether there could be any economy found in the construction of carriage-ways led to a rather lively and amusing discussion. The chairman, Alderman Thompson (one of the ablest of chairmen in the conduct of a meeting), mentioned a case where clay suitable for brickmaking was found on an estate, was sent up to the neighbourhood of London to be made into bricks, and came back to the estate in the form of brick rubble for the hard-core for the roads. Why, he wanted to know, instead of paying the carriage of that clay to London and back, could it not be treated on the spot in some way suitable for the purpose and taken direct to the making of the road-bed? The opinion of surveyors present, however, was (and we have little doubt that they were right) that there was no alternative means of rendering the material hard enough for a road-bed. But the papers on the subject, and the discussion, certainly went to show that subsidiary roads on building estates are often made wider than is absolutely necessary, and that economy in that direction might be very well practised.

THE REBUILDING OF ST. MARK'S CAMPANILE.

GR^{EAT} rejoicings have welcomed the completion of the new Campanile of St. Mark's, which has been erected at Venice in imitation of the old one, but we do not know that this jubilation was of the wisest. The old Campanile had been a part of the history of the city; it had grown with the city's growth and importance, and with the lament of the citizens over its fall one can sympathise entirely. But the fact remains that it was an ugly erection, added to at different times without any regard for proportion and architectural unity, and its value was certainly historical rather than architectural. A new campanile built up in the likeness of the old has no historical value; but unfortunately, while this element of interest is lost,

its architectural faults have been carefully and conscientiously repeated. It is difficult to see what Venice gains by the proceeding; she has lost the real thing and built up a sham one at an immense cost, which might have been better expended. But the most important point in connection with the proceeding is the light which it throws on the manner in which architecture is now regarded, in Italy apparently at all events. It seems to consist simply of a worship of the past. In any age in which architecture as an art was a subject of real interest, if an old building fell down the immediate ambition would have been to replace it by something better; more than that, old buildings were deliberately destroyed for the purpose of putting something better in their place, in the proud consciousness of a capacity to do so. Now, an ugly and awkward-looking tower having fallen, the only desire seems to have been to replace it by an imitation; a proceeding which needs no architectural genius, nothing but the requisite cash. If the modern Venetians had been inspired by the genius of their forefathers, what they would have done would have been to organise a grand architectural competition for the design for a new and better campanile, since a campanile they must have. In doing so they would have given an immense impetus and encouragement to tower design, they would have excited the architectural interest of all Europe, and they would most certainly have obtained a finer campanile than the one they have lost. But no; they must have the same thing over again, beautiful or not, because it was there before. How far is such a principle to be carried? If St. Mark's should some day fail (and knowing what one does of Venetian foundations it seems only too possible a catastrophe), will they build a copy of it?

As the Centre Plate in this issue we give two views of the Campanile, the original structure which collapsed on July 14th, 1902, and the new tower which was inaugurated on April 25th by the King of Italy. The old Campanile, had it stood till next month, would have been 1,000 years old. It suffered greatly from lightning and earthquake, and it was these, coupled with the disintegration of the mortar—not any subsidence of the foundations, which were and are thoroughly sound—that brought about the collapse. In the rebuilding the foundations have been widened, the old method of piling being followed. Altogether 3,076 larch piles have been driven, of an average diameter of $8\frac{1}{2}$ in., and 13 ft. in length. They are calculated to carry about 90,000 tons, whereas the weight of the new tower is estimated at 20,000 tons only.

The pile-driving was completed by October 8th, 1904; and then arose a problem of bonding the new foundations into the old in such a way that they should receive and distribute the weight over the new foundation area. The old foundations were incised all round to the depth of 8 ft., and the upper layer of the new platform was laid over the lower layer of the old. This process of bonding virtually decided the fate of the old foundations, only 200 cubic metres of the old remaining as a mere nucleus in the centre of the tower. On the top of the new platform come the new foundations, eleven courses of Istrian stone, dressed and carefully cemented. The blocks are bonded into the old foundations to the depth of 6 ft. 6 in.; and thus, as Mr. Horatio F. Brown points out in the "Times," the new Campanile is carried almost entirely on new foundations and a new platform, and partly on new and partly on old piles.

The base of the old Campanile consisted of five steps, all of them originally visible. When the Town Council voted to rebuild the tower "where it was and as it was," they had not asked the question "as it was when it fell, or as it was when it was built." Were all five courses to be visible as when the Campanile was built, or only two and a half, as when it fell? After a long discussion, the question was decided in favour of five steps; and that marks almost the only difference between the new and the old towers; except, also, that the new Campanile has a lift.

The building of the new shaft presented no great difficulties. It is a magnificent piece of brickwork, and reproduces the old shaft exactly, save that for the sake of lightness there are only four instead of eight pilasters in the inner tower. The bricks were specially made at Casale on the Sile near Treviso. They are of a peculiar size, 12 in. by 6 in. by 3 in.; and as they contained a considerable amount of salt, which was apt to produce a white efflorescence, before being used they were soaked for seven days in tanks whose water was changed every twelve hours. The colour of the new shaft is, perhaps, a little rosier than that of the old.

The bell-chamber is an exact reproduction of the original. The five bells, except the largest, which was intact, have been refounded at the charges of his Holiness the Pope; and his name, perhaps for the first and only time, appears in conjunction with that of the King of Italy in the commemorative inscription. The attic above the bell chamber has recovered its two lions of St. Mark, defaced at the time of the French occupation; the shell of the new pyramid is of reinforced concrete instead of brick, the outer casing of copper and the ribs of Istrian and Verona marble being identical with the old; the angel has been recast, but is carefully modelled on the angel of 1822. In short, the new tower faithfully reproduces its fallen predecessor. The loggetta at the foot of the Campanile, erected by Sansovino in 1540, originally used as a meeting-place for Venetian nobles, and later as a guardroom for the soldiers during the sessions of the Great Council, has been perfectly reconstructed, as practically all the fragments of the four bronze statues that adorned it, its decorative reliefs, and its bronze gates, have been saved and used again. The exact dimensions and measurements were found in old MSS.

The cost of the rebuilding has been £88,000. Its height is 352 ft. Signor Doughi was the architect in charge of the work.

SOME OLD VIEWS OF ST. MARK'S CAMPANILE.

1, as given by Jacopo de Barbari, 1500; 2, as finished by Mastro Buono, 1513;
3, as given in Breydenbach's "Peregrinatio," 1486.

THE REBUILDING OF ST. MARK'S CAMPANILE, VENICE.

PROFESSIONAL PRACTICE
AND A CODE OF ETHICS.

Extracts from a paper in which Mr. C. McArthur Butler, F.C.I.S., opened a discussion on this subject before the Society of Architects on April 11th, were given in our issue of April 17th. A condensed report of the ensuing discussion here follows:—

DISCUSSION.

Mr. B. G. Lovell, A.R.I.B.A. (Member of Council), in moving a vote of thanks to the secretary, said he thought that the idea of forming a Board of Professional Control was a very excellent one, provided an assurance was forthcoming that it could be got together promptly. If, with the object of gaining greater unity, they were to wait for the co-operation of all the allied societies, the Royal Institute, and the other institutions mentioned, he could easily foresee that the matter would drag on for as long as their previous negotiations with regard to registration. The Society prided itself upon the fact that it was the forerunner of registration, and he saw no reason why they should not adopt the same attitude with regard to the suggested Code of Ethics, and he thought the Council would be acting in the best interests of the profession by pushing the matter forward immediately. He could not see any difference between putting the architect's name on a board and having it engraved on a corner-stone of a building; and he would urge that a very comprehensive view of this question should be taken when the matter came up for consideration.

Mr. A. O. Collard, F.R.I.B.A., in seconding the vote of thanks, said the subject appealed to him as a lecturer at the A.A. School for something like fifteen years on professional practice. He thought it would come as a surprise to many architects that any such suggestion as a body to control professional practice and to institute a code of ethics was necessary or desirable. Many of them, he assumed, managed to get along in the profession without committing any professional enormity. It would be a very delicate matter, but he would like to receive some indication of the extent of the misdemeanours which actually were known to happen and which had occurred in the past. He thought the offences, whatever they were, should be tabulated and classified. He thought Mr. Butler's suggestion might be carried out so far as requesting the different societies to appoint delegates to consider whether a Board of Professional Control was really desirable, and it would be absolutely necessary to decide the matter one way or another in the minds of those gentlemen by informing them definitely of the nature of the things which had happened.

With regard to specific charges of architects, he noticed that it was suggested that a minimum charge should be made. He thought with Mr. Butler that it was a very doubtful advantage to have any fixed charge whatever, and that it would be better to leave it open so that a man could charge whatever he thought himself worth. There should be nothing to prevent a man charging 10 per cent. if he thought he could get it, as they were well aware that in certain special work a man might have trained himself thoroughly and the value of his work be worth two or three times as much as the ordinary scale gave him.

With regard to advertising, he could not see the difference between putting one's name on a board and putting it on the building after completion. Although he had never done either himself, he thought if the architect were to put the design on the board as well as his name it might help matters, because they could then see the beauty or the wretchedness of the building, as the case might be, side by side with the name of the architect who was responsible for it.

Mr. W. H. Seth Smith, F.R.I.B.A., after enumerating the points or principles of policy or conduct that, in operation, had vastly improved the public esteem for professional men, said that the policy was in short:—(a) To benefit the public by giving the very best of services; (b) to benefit their members by fellowship and by due preparation for professional duty, and thus enable them to reap the confidence, work, and pay which invariably result from such a policy; (c) By organised resistance to frustrate attempts on the part of individuals, corporations, or of the legislature to impose unfair or unjust conditions on their members. Should such moral or legal resistance be abortive, the obvious and final resort was the corporate withdrawal of service. This weapon the medical profession had been obliged for the first time (last winter) to threaten to use, and architects, though not so immediately affected by democratic employment and democratic legislation, have had to adopt in a more limited degree by their recent agreement not to enter competitions under conditions unfair to their members. It is abundantly clear, therefore, that the confidence they had won has been much more due to an ethical policy rather than to one of expediency, and in discussing the question he hoped their past experience would encourage them to continue on these general lines while seeking to elucidate, emphasise, and enforce them. The great value of statutory registration would be, as Mr. McArthur Butler premises, the bringing of the at present detached architect under a

commonly accepted code of architectural etiquette, but legislation directly or indirectly compelling any man to join a professional body would be a gross breach of the liberty of the subject, and should never be suggested in applying for a Registration Act.

Mr. Arthur J. Martin (President of the Institute of Sanitary Engineers) said that with regard to some points of professional conduct, the value of rules of conduct lay not so much in the hard-and-fast line which they drew as in that it defined for the information of all concerned what should be the practice of the profession. He did not think it was practicable to enforce a scale of fees; it would be a mistake to treat it as a maximum, and it would not be fair to the young men to enforce it as a minimum; and on the other hand, if a scale were not rigidly enforced it would be useless. It would be of very great use for a professional man to be able to say that the recognised scale of charges for such and such work was so much, and that a man was not justified in accepting anything less unless he was a young man. The great question appeared to him to be that no person should be at liberty to represent himself as an architect or engineer without possessing the necessary qualifications for the title. Personally, he could not see any reason whatever why an incompetent man should be at liberty to practise in either of these professions any more than he was able to as a solicitor, medical man, or dentist. In their profession, just as much as those he had mentioned, the incompetent man was a danger to the life and health of a large number of people. It was not a matter for the profession to determine, but one which the general public had a right to demand. What that qualification should be was another matter.

Mr. A. S. E. Ackermann, B.Sc., A.M.Inst.C.E., said he thought more attention might have been drawn to the professions of law and medicine, from which they might learn a very great deal

ST. MARK'S CAMPANILE, VENICE: VIEW OF BASE IN COURSE OF ERECTION.

from their experience. Some years ago he had had occasion to make enquiries of the British Medical Association in regard to the question before them, and he was astonished to find how deeply they had gone into what was more or less an unwritten law. Quite recently a code of ethics in connection with medical consultations had been published, giving details even so far as the order in which each man should enter the patient's room.

Mr. A. Alban H. Scott, M.R.San.Inst. (Member of Council), said that most of the discussion had turned on the question of architects' fees, which he thought a great pity, because architects usually looked upon their fees as a secondary consideration, and did their work for the work's sake. With regard to the remarks which had been made as to the principle of payment by commission being an immoral arrangement, no doubt it was an unhappy one, but the young architect, he thought, fully realised that his career would be made not by his financial income or by piling up the cost of the work, but by getting economical buildings for his client and making, and afterwards maintaining, a proper reputation. Architects would benefit by a greater professional unity. He thought that advertising should not be allowed in any form. If it were permitted at all it would be very hard indeed to draw the line anywhere; for instance, if an architect were allowed to put his name upon a board it would be necessary to make a rule limiting the height of the letters, and so forth. Nothing was more degrading, he thought, than for a professional man to have his name appearing on a board in letters two feet deep. Fancy a lawyer or a medical man committing such an indiscretion! Architecture would never gain the respect of the public if such things were permitted. He did not think a job was ever gained by advertising, and it was simply lowering the profession to the position of a trade. He thought the suggested Board of Control an excellent idea, because in the case of an honourable architect having suggestions made to him regarding his reputation it would be quite a simple matter for him to submit the case for thorough investigation by the Board of Control, when he would be immediately protected from further slander. The scale of charges should, he thought, be entirely omitted.

Mr. A. Lawrence Cox, F.S.I., A.M.Inst. E., said with reference to advertising that some professional bodies raised no objection to it, while others did. He thought it made very little difference whether they as a Society objected or not, for architects would advertise in some form or another, although there were some extraordinary creatures who apparently did not care for publicity or remuneration of any sort. He saw no reason why advertising should not be permitted, so long as it was indulged in moderately.

The Chairman (*Mr. Percy B. Tubbs, R.I.B.A., Vice-President*) then summed up the discussion, and said he personally hoped that a Code of Ethics would be adopted, and that the Council of the Society would appoint a committee to inquire into the matter. He would very much like to see a Board of Professional Control as suggested by Mr. Butler. He thought it quite possible that if it were properly constituted it might ultimately develop into the registration authority if they were so fortunate as to get a Bill through Parliament. With regard to the charging of commission, he quite agreed that it was absolutely wrong

in principle, and ought to be altered at the earliest possible moment.

A vote of thanks to Mr. Butler was then put to the meeting and carried with acclamation.

Mr. C. McArthur Butler said he would reserve his reply—for the Proceedings.

The following extracts are taken from communicated criticisms:—

Mr. G. A. T. Middleton, A.R.I.B.A.: Perhaps it may be open to debate whether a written code is so good as one which is understood, as leading to possible harsh decisions when circumstances might warrant a lenient view being taken. At the same time, the value of strict discipline is great, and machinery for its universal enforcement, with safeguards for even-handed justice, are much needed. His impression is that the inclusion of some representatives of the public on the Board of Control might be essential to secure this in all cases. It has also been suggested to him that a point should be made of forbidding a custom, by no means unknown, of giving commissions for the introduction of work and for information of work likely to come, to officials, perhaps, of public bodies, enabling members of those bodies to be "got at."

Mr. A. B. Hayward: The ownership of drawings is one of the most important things to be remedied at the present time. It is most unjust that the client should be considered the owner of them in the eyes of the law, they being merely the instruments employed by the architect to produce the building ordered by the client, and as such should be as much the property of the architect as his tee-square or five-foot rod. The scale of fees as sanctioned at present appears to work fairly well on the whole, except when it comes to the question of paying for applications to County Council, Local Councils, drawings for District Surveyor for certificate or, in the case of public buildings, for his use. The architect must be paid for these, yet the number of them required has increased considerably of late years, and the scale as issued by the R.I.B.A. hardly makes it sufficiently clear that fees for such work are over and above the 5 per cent., and in the scale sufficient emphasis is not made of the fact that these charges in some cases amount to a considerable sum, and clients are not clearly led to understand that this work entails much extra labour and trouble to the architect. With reference to advertisement the writer thinks the modern tendency originated by the Garden City movement exhibitions, and the newspaper Cheap House Brand of exhibition, is a mistake, and does harm to the profession. It is exceedingly difficult, if not impossible, for a young man not to participate in these when he sees his professional brethren, more distinguished than himself, doing so, and prize cottages being put up at almost impossible prices; and in his opinion, it would be entirely in the true interests of architects if the various governing societies would discourage them as much as possible, and do all in their power to persuade their members that it is undignified and unprofessional to take part in them. If they were frowned upon by the professional powers that be, he thinks they would die a natural and unregretted death. Illustrations of one's work in journals, books, papers, collections of designs of houses, etc., etc., seem to him to be quite fair and legitimate, and, if considered advertising, is legitimate advertising.

Mr. H. Freyberg, F.S.I.: If in drafting any code of ethics for professional con-

duct all architectural, surveying, and engineering institutions could first agree to certain general principles applicable to all members of those institutions, it would not only bind them, but also could not fail to influence unattached people and the general public. The general principles being agreed, each society could then deal with details particularly applicable to its own profession, and could formulate a scale of charges. This latter would necessarily have to be on elastic lines, and should in the writer's opinion insist on a minimum.

Mr. H. Guicharde Todd, F.S.A. (Scot.): The practice of ethics cannot be codified in relation to architecture any more than it can be codified to the practice of art, to which it is sister in ideal and temperament. To attempt to do so is to degrade the profession to mere commercialism. Experience has demonstrated beyond dispute that expressed codes play into the hands of the unscrupulous, who get round the written law and so justify their sordid dealings. It is useless to tell them that they have done a mean thing when they can triumphantly point to the written code and ask, "Wherein have I offended?" The true artist with the ethical spirit, not the written code merely, guiding him, will be more defenceless than ever, for the soul of real brotherhood in art will have been buried in this penal code, and there will be none to help. The real protection for the struggling artist or member of any honourable profession is the consciousness that he belongs to a body, to the members of which honour and honourable dealing have become as much part of their existence as the atmosphere they breathe. The integrity of the members of the Bar is undoubted. The personal honour of its members is their most cherished attribute, although the temptations must at least equal the temptations of the architectural profession. The Bar has no written code of ethics. There is something better—an unwritten code, infringement of which makes the defaulting member liable to be ostracised by his fellow-members of the Bar.

THE PICCADILLY IMPROVEMENT SCHEME.

The delay in connection with the carrying out of the Piccadilly improvement scheme has again been the subject of a letter addressed by the Westminster City Council to the Office of Woods and Forests. The council ask for an assurance that the work shall be begun at once and carried forward without loss of time, the purchased land being added to the public way.

It was originally contemplated to complete the scheme before the Coronation season, but a deadlock arose in connection with the rebuilding of Nos. 19, 20, Piccadilly, known as Denman House; and although £70,000 was paid as compensation to the parties concerned, so long ago as February, 1911, the Westminster City Council are still waiting to get possession of the semi-demolished premises.

In answer to a previous letter of protest, the Office of Woods explained that the delay arose from the fact that complex negotiations were in progress before the Crown as freeholder and various parties possessing leasehold interests, which, it was hoped, might result in the rebuilding being carried out so that the front elevation may be a completion, architecturally of Mr. Norman Shaw's design of the Picca-

dilly Hotel. The new protest is not based on purely æsthetic grounds, but is the result of a series of complaints from tradesmen in the neighbourhood that the delay in the rebuilding of the premises has been a source of serious handicap to business during the last twelve months.

TEST OF A KAHN BUILDING AT YORK.

The new Lecture Theatre which has been added to the Yorkshire Philosophical Society's Museum at York is now rapidly approaching completion, and the opening ceremony, which is provisionally fixed for June 6th, will be performed by Dr. Bonney, the distinguished scientist, and former President of the British Association.

Recently, the building, which is entirely constructed of reinforced concrete on the Kahn system, was inspected by the York City Engineer (Mr. F. W. Spurr), and the beams were thoroughly tested. The following are the particulars of the testing:—

Preliminary Tests.

Some difficulty was experienced at the commencement of the works in securing a satisfactory foundation for the many pillars on which the building is supported, owing to the existence of the old ruined stone walls, on which some portions of the new building are constructed. Much time and care were expended in examining the subsoils and in testing and calculating the bearing capacity of the clay bed which was found about 5 ft. below the present surface, which clay bed is the same one on which the ruined walls of St. Mary's Abbey are resting. How well these tests and calculations have been made is shown by the fact that in no single instance in the whole of the building is there a sign of an uneven settlement.

Concrete and Steel.

The materials that have been used in the construction of the building are screened river pebbles, gravel sand, and Earle's "Pelican" brand Portland cement, the steel used being Kahn open hearth steel. Frequent tests have been made of the cement, concrete, and steel, and all the results were wonderfully uniform and good. Great care was used in putting together the wood forms in order to avoid the necessity of treating the outside of the building with any form of plaster work, and the present surfaces of the walls, mouldings, and cornices, etc., are just as they have left the wood-work, with the exception that they have been cleaned down. The whole of the enrichments have been cast *in situ*, and are remarkably sharp and well defined.

A Record Span.

The roof is also in reinforced concrete, and is constructed at a height of 31 ft. 6 in. above the lowest level of the lecture theatre floor. It is claimed that the beams carrying the larger portions of the roof are the longest span of any flat beams in this country—namely, 46 ft. 8 in. clear span. The building has been designed by Mr. E. Ridsdale Tate, architect of the city, with Mr. W. Oldfield as chief of the works, and the contractors are Messrs. J. and T. Biscoomb and Sons, York, who have recently carried out works of a similar nature in that district.

Corporation Tests.

The building has recently been tested to meet the requirements of the York Corporation, who have to safeguard the

public in respect to the stability of buildings of a like nature. Eight very severe tests were applied in different places, and the city engineer reports that in no case did the deflection approach the amount allowable in work of this description. The test loads applied were, with the exception of the roof test, $2\frac{1}{2}$ cwts. to the square foot, being $1\frac{1}{2}$ times the load which the structure was designed to carry, and when the fact that the building has been designed with a safety factor of 4 is taken into account, it will be seen that better results it is nearly impossible to get.

The first test was on one of the beams carrying the lower portion of the lecture theatre floor, having a clear span of 26 ft. 9 in., and supporting a floor area of 26 ft. 9 in. by 10 ft. 3 in. This area was loaded up with 32 tons of ballast in bags equal to $2\frac{1}{2}$ cwts. per square foot, and the greatest deflection was only .066 of an inch, practically 1-16th of an inch, while the deflection allowable was .890, or nearly 9-10th of an inch.

The second test was made by loading a floor area 10 ft. by 10 ft. 3 in. with $13\frac{1}{2}$ tons of ballast, the deflection being .031 of an inch, or 1-32nd of an inch, when .33 of an inch (1-3 of an inch) was allowed.

The third test was applied to one of the long beams of 35 ft. clear span, carrying the stepped floor to the lecture theatre, and supporting a floor area of 35 ft. by 10 ft. This area was loaded with $40\frac{1}{2}$ tons of ballast, the actual deflection being only .047 of an inch, or about 1-20th of an inch, when any deflection up to 1.166, or 1 1-6th inches would have been allowed.

Test No. 4 consisted of $11\frac{1}{4}$ tons placed on an area 8 ft. 10 in. by 10 ft., supported by one of the secondary or raking beams. This deflected only .027, under 1-32nd of an inch, when .294 was allowed.

Test No. 5 consisted of loading one bay 8 ft. 10 in. by 12 ft. of the stepped floor to the gallery or upper portion of the lecture theatre with $13\frac{1}{2}$ tons of ballast, which produced a deflection of .015 of an inch (under 1-64th of an inch) when a deflection of .294 was provided for.

Test No. 6 was made by loading one of the long roof beams, 46 ft. 8 in. clear span and supporting a flat area of 46 ft. 8 in. by 10 ft. This area was loaded with $12\frac{1}{2}$ tons of ballast, being 60 lbs. to the square foot. The resulting deflection in the centre of the beam was .043, or just over 1-32nd of an inch, when a deflection of 1.555 or over $1\frac{1}{2}$ inches was allowable. Two other smaller tests were made on the roof, and the results were practically the same.

Mr. F. W. Spurr, the City Engineer and Surveyor of York, reports that "the deflections recorded were remarkably slight, and the tests throughout were very satisfactory"; and it is therefore almost superfluous to add that the results that have been obtained have given great satisfaction to all concerned. The accompanying table of the results of the tests was prepared in the City Engineer's Office, York:—

"City Engineer's Office, York,
17th April, 1912.

"Tests of floors and roof at New Lecture Hall, Museum Gardens, 16th of April, 1912.

The test load applied in each case was equal to $1\frac{1}{2}$ times the load for which the structure had been designed to carry—that is:—

Floors = 168 lb. by $1\frac{1}{2}$ times = 252 lb per sq. ft.

Roof = 40 lb. by $1\frac{1}{2}$ times = 60 lb. per sq. ft.

Test.	Clear Span.	Load in tons structure designed to carry	Test Load in tons.	Total deflection at centre of span in decimals of an inch
Test No. 1. Beams carried by columns numbered 24 and 25	26' 9"	21	32	.066
Test No. 2. Ground floor between last-mentioned beam and the front wall of building	10'	9	$13\frac{1}{2}$.031
Test No. 3. Beam carried by columns numbered 20 and 21	35'	27	$40\frac{1}{2}$.047
Test No. 4. One secondary or raking beam carrying the stepped floors	8' 10"	$7\frac{1}{2}$	$11\frac{1}{4}$.027
Test No. 5. One bay of stepped floor to Galleries	8' 10"	9	$13\frac{1}{2}$.015
Test No. 6. One main roof beam	46' 8"	8	$12\frac{1}{2}$.043
Test No. 7. One secondary roof beam	8' 6"	2	3	.027
Test No. 8. One bay of roof flat	8' 6"	2	3	.027

"In no case did the deflection approach the amount allowed in work of this description."

OBITUARY.

Mr. D. N. Brims.

Mr. David Nicholas Brims, who died on April 16th after a short illness, was the founder of the firm of Brims and Co., Ltd., contractors, of Newcastle-on-Tyne, but had retired from active business five years ago. During his career Mr. D. N. Brims carried out many important engineering contracts on the Tyne and elsewhere, amongst them being the first Dunston Staiths for the North-Eastern Railway Company, the large dry dock of the Blyth Dry Dock Company, the quays and shipbuilding berths at Elswick Shipyard, a large dry dock at Bilbao, Spain, and very many wharves, harbour works, bridges, etc. He was one of the first contractors in England to carry out large works in reinforced concrete, the Co-operative Wholesale Society's building on the Newcastle Quayside being one of the first of its kind in England.

R.I.B.A. Necrology.

At the meeting of the R.I.B.A. held on Monday, April 22nd, it was announced that Mr. E. A. Kent, the eminent architect, of Buffalo, New York, was among those who had lost their lives in the "Titanic" disaster. A vote of condolence was passed to the sister of the deceased, his only relative.

The death was also announced of Robt. John Macbeth, Fellow, of Inverness, N.B. John Bevan Phillips, Associate, of Wyoming, U.S.A., Henry Shackleton, Associate, of Morecambe, and Edward Ashby Smith, Licentiate, of Acton Park, W.

THE ROYAL INSTITUTE LIBRARY AND SOME OF ITS CONTENTS.*

BY C. HARRISON TOWNSEND, F.R.I.B.A.

Mr. Harrison Townsend's paper serves a most useful purpose in calling attention to the treasures housed in the R.I.B.A. Library. Most of the critical comment and ana which accompanied Mr. Townsend's paper have had to be omitted owing to the limits of quotation imposed.

ONLY those who have carefully and systematically examined our collection of books know how fortunate we are in possessing many rare volumes of early works on architecture which are of exceptional interest. Thus, the library contains an extremely rare first edition of "The First and Chief Groundes of Architecture," by John Shute (1563). We have, from the Royal Library of France, the "Recueil d'Estampes de différents auteurs concernant les batiments, les tapisseries, tableaux, conquêtes et autres sujets qu'on trouve dans les maisons royales" (Paris, 1660-69), a magnificent series of twenty-two folio volumes, with wide margins, and many extra prints (and, in some cases, reversed prints, probably unique), of the superb engravings. Our collection of the works of Vitruvius approaches being a complete one, and numbers sixty-eight volumes, in Latin, French, Spanish, Italian, German, Dutch, and English, ranging downwards in date from the "editio princeps" of 1482-92. Again (and here I must stop with my illustrative examples of some of the more important of our books), we have, besides Alberti's "De re Edificatoria" (1512) and others of his works, his "Hecatombila," a volume which, if not very germane to architecture, is still excessively rare and almost unknown.

We are happy in possessing a considerable number of original architectural drawings, either designs, or sketches or measured drawings of existing buildings, in many cases executed by men of note, and ranging from, say, Scamozzi, in the sixteenth century, to Burges and Nesfield of our own time. The very valuable Burlington-Devonshire collection (which, thanks to the initiation of Mr. Crace, was in 1894 placed in the custody of the Institute) consists of no less than seven hundred bound volumes, and upwards of 300 miscellaneous drawings. We do not own many drawings of early date. Our oldest "Metal Work"—original sketches on both sides of one sheet, apparently the work of an artist of the fifteenth century—sheet containing drawings on both sides, which was presented to the library in 1886 by Sidney Smirke, who was the younger brother of the better known Sir Robert Smirke.

There are two drawings—exterior and interior architectural compositions—by Jacob van der Ulft (1627-1688), drawn in Indian ink, and delicately touched with wash.

A volume of drawings and sketches, presented to the library by Professor Donaldson, contains eighty drawings of scenes and altar-pieces. The date of the work is about 1713. Belonging to the Evelyn collection are five valuable sheets of drawings which, there is every reason to believe, are from the hand of Inigo Jones. Two of these represent a promenade designed, in the one case, for the masque of "Juno's Court, 1633," and in the other for the "Queen's Masque of the Islands, 1634."

In the Crace Collection of Views of Old London, in the British Museum, is a series of four prints, engraved by Loggan, 1661, representing four triumphal arches. Of these we have in the library the original drawings.

A remarkable volume consists of 120 drawings by some of those draughtsmen of the late seventeenth and early eighteenth century, who, I am afraid, come within the category of those lately described by Professor Blomfield as "in dustrious builders of 'Châteaux d'Espagne,' indefatigable and unprofitable designers in the air." The book contains sketches executed in pen-and-ink, or sepia, or Indian ink wash. We find in it some by Giuseppe Galli, probably executed between 1720 and 1730, consisting prin-

cipally of theatrical decorations and designs for scenes. There is also a pen-and-ink drawing, of about the same date, by Oppenordt, who was a pupil of Mansart and the architect, amongst other work, of the transepts of St. Sulpice. We find some good drawings of a scenic and barocco design by Panini, known as a painter of the Campagna and of Roman ruins, by whom the Institute possesses an oil painting of the Colosseum on its walls in the Council Room. By Pierre Puget, who was not only an architect, and a "great sculptor" (as he is termed by Mr. W. H. Ward), but a painter also, and was, on these three qualifications, called by his flattering admirers, in his own day, the "Michelangelo of France," there are also some examples. This "universal genius," during his stay in England, designed Walpole House, in Bloomsbury, on the site on which the British Museum now stands. By Desprè's is an important drawing in water-colour of the Celebration of High Mass, more noteworthy, perhaps, for its figures and accessories than for its architecture, and executed evidently about the middle of the seventeenth century.

John Talman, son of the elder Talman, who designed Chatsworth for the first

SKETCH FOR A FOUNTAIN BY OPPENORDT.

DETAIL DRAWING BY DECIMUS BURTON.

Duke of Devonshire, was an architect of considerable note in the early part of the eighteenth century, and, as a volume of his sketches and plans shows, designed houses for Lord Carlisle and a house for "Ye Lord Devonshire at Lambs' Conduit Fields." Before practising, he travelled to Rome with W. Kent.

A folio volume of drawings of Whitehall Palace contains the drawings made for Kent's edition of the works of Inigo Jones (1727) by Flitcroft, who was not only an accomplished and delicate draughtsman, but an architect of note in his day.

The original drawings of R. Wood's "Ruins of Palmyra" and "Ruins of Balbec or Heliopolis" are contained in two large volumes of laboriously careful sketches.

There is a volume of sketches by Chambers and Yenn, the latter of whom was Sir William's pupil, and became an architect of some distinction and an R.A. The drawings consist of "designs for fronts, projects for staircases in the grand manner, garden-houses," etc., but, being unsigned, it is not possible to ascribe the drawings to either of the two artists.

In 1784, George Hadfield received the first gold medal for the travelling studentship at the Royal Academy. He made use of his tour abroad to make measurements and collect data for the restoration of the Temple of Fortune at Palestrina, or Præneste, near Rome.

Hadfield may be further remembered as the architect of a considerable portion of the Capitol of Washington.

The library possesses the original water-colour drawings by James Stuart from which the engravings were made for Stuart and Revitt's "Antiquities of Athens," and also a small volume of his sketches and MS. notes.

There are in the library nine large drawings by Hardwick—plans, elevations, and sections of the Pantheon from his own measurements. Another large volume by him is a scrap-book in which have been mounted sketches and measured drawings, most of which he made in 1778. This conscientious, but not very inspired, book is the work of the father of the better-known Philip Hardwick. He was a pupil of Chambers, and obtained, in 1768,

the first silver medal offered at the Royal Academy for the class of architecture. J. M. W. Turner was at one time in his office.

To those who are interested in the work of the late eighteenth century, when the influence of the Adam brothers was supreme, the book of sketches of ornamental friezes from original models in the possession of Joseph Rose will appeal. The Rose family were engaged in the execution of plaster enrichments, for which they made the models from the designs of Wyatt, Stuart, and the two Adams. The drawings, 330 in number, were executed by Joseph Rose, the son, and the artist member of the firm, in 1782.

By Sir Robert Smirke (of whom we possess a bust, which is in the Common Room), we have eleven large water-colour drawings, executed during his travels in Naples, Sicily, and Greece, between 1801 and 1805.

There is a volume by Henry Parke, an architect of the early nineteenth century whose name should be known to members of the Institute as the designer of the medal which was given by his brother-architects, in 1835, to Sir John Soane, and the use of which is allowed us annually for the Soane Medallion. Parke's widow presented these 500 and 600 drawings, which are the result of his tour through Italy, Sicily, Greece, and—a somewhat rarer place to visit in his days than in ours—Egypt, in 1824. Many of his measured drawings were done in conjunction with his fellow-architect, Scoles, of whom there is a framed portrait on our walls.

One of the original founders of the Institute was John Goldicutt, who was born in 1793, and died in 1842. By him we possess about 300 sketches, and 100 designs and projects of his own. Many of the sketches are of Pompeian decorative work, probably done for his "Specimens of Ancient Decorations from Pompeii," published in 1825.

There is a volume of strongly coloured drawings by George Wightwick (1802-1872), an extraordinarily voluminous author on things architectural. They are the originals of his "Select Views of the Roman Antiquities," lithographed by T. N. Baynes, and published in 1827, and are useful in showing us the unexcavated state of the Colosseum and the Forum. Another volume of his is a scrap-book of sketches, many of which are measured work done in Italy. We have a further volume to which Wightwick gives the somewhat imposing title of "My Liber Veritatis." It contains drawings of vases, and sketches in France and Venice, and also the rough sketches for the above work; and, finally, this most prolific of architectural draughtsmen has left behind him a huge collection of large and very vigorously coloured drawings which had served to illustrate his many lectures.

A volume presented by Professor Donaldson in 1864 contains some water-colour sketches, done between the years 1816 and 1819, by Joseph Woods, who, it is interesting to note, was a founder, in

DETAIL DRAWING BY DECIMUS BURTON.

SECTION OF ST. PETER'S, ROME, DRAWN BY J. GOLDICUTT (1793-1842).

1846, of the London Architectural Society, of which our Institute is the lineal descendant.

A curious series of sketch and note books—no fewer than sixteen volumes of closely written and minutely drawn notes—are the result of John Wolfe's three or four years of travel in Italy, Greece, and France in 1820.

Of Elmes's work, we have a large collection of drawings and designs, and full-size and other details. There are, mostly drawn by his own hand, several interesting alternative treatments of St. George's Hall, both interior and exterior. Amongst these was a rough perspective sketch—a

The name of T. L. Donaldson seems to carry us very far back, for, though he only died three years before Nesfield, we have two volumes of sketches done in Greece and Rome as early as 1819 and 1821. Curiously enough, one of these is a large volume of sketches of Gothic work, to which one would not have imagined he had much leaning. The list of the works of Donaldson in our library is, I think, longer than that of any other architectural author. He runs things very close with Vitruvius, the many editions of whose works I have already referred to.

A donation to the library by Mr. C. E.

well drawn, on tinted paper in black crayon touched with white.

By William Burges we have three scrap books in which have been inserted drawings of original designs of stonework, and of silver and goldsmith's work, domestic and ecclesiastic. A later acquisition, through the generosity of Sir W. Emerson, is the pocket-book lately presented by him to the Institute. It consists of thirty-six vellum pages with sketches in brown ink, annotated in Burges' usual almost black-letter script, and still contains, interestingly enough, his own crowquill.

There are four volumes of a modern architect whose influence on the architec-

DRAWING OF PROSCENIUM FOR "THE QUEEN'S MASQUE OF INDIANS," BY INIGO JONES.

facsimile of which appeared in the March issue of the "Architectural Review." I sent a tracing of this sketch to that journal, which has taken so important a part in the debate upon the proposed treatment of the south end of the building, as rather valuable evidence that Elmes himself had entertained and finally abandoned the intention of finishing each end of the podium wall with a monumental pedestal bearing a horsed figure. Amongst his drawings are three large tinted perspectives (submitted in two cases in competition), but two of these, I think, evidently show the hand of Thomas Allom, whose vogue as a "perspective colourist" was so great in the middle of the last century.

Sayer, made some three or four years ago, was a volume by Alexander Roos, a German architect who was brought by Beresford Hope to England. It contains many beautifully executed little drawings of coloured decoration. Some forty or fifty of these are of Pompeian walls and ceilings, but, unfortunately, a large proportion of the remainder are without any indication as to their source.

Decimus Burton, the architect of the Wellington Arch, and a former Vice-President of the Institute, presented to the library the year before he died (which was as recently as 1881) forty-two drawings of classic relief ornament, stone or marble, carved decoration of architraves, strings, etc. They are drawn, and

ture of our own time has, in the opinion of many, not yet been fully recognised. Some of the evidences of the amazing fertility known to many who, like myself, were brought into close contact with William Eden Nesfield, are to be found in the four volumes of his sketches which the Institute possesses.

All the drawings of R. J. Johnson's "Specimens of French Architecture," published in 1864, are contained in two of the three volumes presented by his widow, the remaining volume consisting of sketches of English Gothic work, the execution of which is not on the high level of the French sketches.

In 1867, there were presented, through Professor Donaldson, by Texier (himself

a gold-medallist of the Institute in 1866) five volumes of sketches and details, in gold and colour, of mosques in Constantinople, one volume dealing specially with St. Sophia.

The volumes of Devey's sketches are somewhat disappointing. Not indeed that they are otherwise than beautifully drawn and touched with colour in quite a charming way, but that they happen to deal principally with one branch of his sketch material only. The majority of the drawings are of chimney-tops; and though they cover a great deal of ground, and comprise notes made of these throughout England and in Germany and Holland, the volumes are not of very great interest. There are, however, a few sketches of French towns, such as Harfleur, Rouen, etc.

A collection of very beautiful drawings is contained in two volumes, one of twelve sheets and the other of thirty-three, of the coloured decorations of Norfolk and Suffolk churches. The larger volume deals with the well-known series of screens, and the smaller containing principally roof decoration. These drawings, which were executed by G. Y. Wardle, with very charming feeling for his subjects, show a delicate and an accurate appreciation of the work of that great school of English art of the early sixteenth century which has not yet received its meed of recognition.

DISCUSSION.

Mr. R. Phene Spiers, proposing a vote of thanks, said a large number of drawings had been shown on the screen, only a few of which he knew the existence of in the Institute collection. Schute's book, he said, was published in 1563, and further editions appeared in 1576 and 1584. Now that we had established a School at Rome, it was of interest to recall that Hardwick's book contained measured drawings of the Villa Hadrian, prepared in 1777; but the most interesting drawings were those by George Hadfield, who was a travelling student in 1790, and who provided the only instance of a student doing a series of drawings in the manner of the modern Grand Prix students who went to Rome. A description of all Nesfield's drawings, he continued, appeared in the *Institute Journal* for 1895. Mr. Spiers recalled how Nesfield delighted to spend his time in the Houses of Parliament making sketches of Pugin's work there. Referring to Mr. Townsend's remarks with respect to possible competition in the acquisition of drawings between the Institute and South Kensington, Mr. Spiers said he had sent about 1,400 drawings to South Kensington simply because the necessary accommodation was not available at the Institute. At South Kensington they were catalogued and made accessible to students.

Mr. E. F. Strange, Assistant Keeper, Victoria and Albert Museum, seconding the vote of thanks, said that only last year they acquired some drawings by John Yenn. Yenn designed a large amount of furniture, among other things, and was also responsible for much of the decoration that was attributed to better-known names. With regard to the drawings of East Anglian rood screens, by Wardle, at South Kensington, they had a considerable number of drawings of the same subjects which were commissioned in 1865-1867. Apparently Wardle had exceeded the commission, and the additional drawings were those in the Institute collection. All the drawings at South Kensington, he continued,

were catalogued and topographically indexed, so they were able to do more for the Institute than they could do for themselves.

Mr. Rudolph Dircks having commented on some of the contents of the Library,

Mr. W. H. Ward said there were many gaps in the Library which required filling in. Columbia University, New York, had been known to spend £1,000 in one year upon the acquisition of books; the Institute of Civil Engineers spent £600 annually, half of that sum being absorbed in binding; but the Institute spent only £150, of which £40 or more had to go in binding, part of the remainder being put towards the Loan Library. If they could only have £30 or £40 allocated annually for the purchase of duplicate books for the Loan Library, and a clear £150, apart from binding, for the Reference Library, he thought the Institute would be in a much better position.

Mr. Herbert Baisford suggested that since Mr. Townsend had confined himself to the Institute's collection of drawings, it would be interesting to have at some future date, perhaps by Mr. Dircks, a paper dealing exclusively with the books themselves.

Mr. E. Guy Dawber, who was in the chair, summed up the discussion, observing that when the finances were on a better footing he hoped they would be able to increase the Library allowance.

Mr. Townsend, in reply, said that with respect to the Wardle drawings, those in the Institute collection were manifestly tracings—perhaps of those at South Kensington—and it would be interesting to compare the two sets.

Mr. Phene Spiers then presented the Institute with some drawings by the late Sir Henry Layard.

TOWN PLANNING CONFERENCE OF LOCAL AUTHORITIES.

About 200 representatives of town and district councils in the southern area of England and Wales met at the Westminster Palace Hotel on April 25th, for a two days' conference to discuss details of town-planning administration. Mr. W. Thompson, chairman of the National Housing and Town Planning Council, presided over the conference.

There were no set speeches, and though many useful papers had been prepared, these were not read. It was felt that information could best be imparted by question and answer, and in this way a great variety of useful experience was exchanged by representatives of authorities who are at present engaged in putting the Act into force.

The question was raised whether existing parks and recreation grounds should be included in town-planning schemes. At Sutton Coldfield a 24-acre park was excluded, but a Carshalton recreation ground was included on the ground that it might, at a future date, be required for workmen's dwellings or some other purpose. In reply to a question whether Crown lands should be included, Mr. Ward, of Portsmouth, stated that the War Office absolutely refused to allow an area of their land to be scheduled in the town plan, though it was being sold and developed as a building estate. The Chairman said this was a case of which public notice should be taken. There was no reason why a Government depart-

ment should be exempted any more than a municipality.

The question of the relaxation of by-laws in order to allow residential areas to be developed on garden city lines produced an animated discussion. Several representatives declared that councils had no power to modify their by-laws, but it was stated that this was done at Southgate and Ruislip, and Mr. Merton, or Rugby, said that in their case the Local Government Board sanctioned the exemption of a defined area from the operation of certain of the model by-laws. The Chairman also stated that the Board had approved of a by-law which allowed modified roads on Mr. Reckitt's garden village at Hull. Mr. Reay Nadin, of Sutton Coldfield, and Mr. H. R. Aldridge, the conference secretary, urged that it would be a fatal policy to relax road-widths and the conditions of road construction by by-law, as this would encourage owners to develop outside the town-planning schemes, and thus prevent the authorities from imposing conditions respecting buildings and the number of houses per acre. Great divergence of opinion was shown in a discussion of the question of the types of roads suitable for town-planning areas. Many members were opposed to the methods of road construction practised on garden suburbs, with grass verges, gravelled paths, and lightly metalled roadways, but this type of roads was defended as lending picturesqueness to residential areas. It was pointed out by the chairman, however, that the object of such cheaper methods of construction was to recompense owners for the restrictions placed upon them by the limitation of the number of houses per acre and the provision of open spaces. If the cost of development were not thus cheapened owners would withhold their consent. The essence of town planning, he said, was to get sunlight, fresh air, and vegetation round the dwellings, and they must take great care not to make the conditions too ideal, or the working-man would be unable to pay the cottage rents.

Mr. Raymond Unwin, architect of the Hampstead Garden Suburb, recommended roads for residential parts of a town-planning area with a width of 16 ft. Some of their 20 ft. roads at Hampstead cost 1½d. per foot for maintenance, whereas 40 ft. roads cost at least 6d. Mr. W. Cullis, of Ilford, and other speakers, contended that the best and most expensive road was the most economical in the long run; but it was pointed out that the roads under consideration were not arterial or business roads, but small residential roads and *culs-de-sac* for an attenuated population.

A resolution was passed requesting the Local Government Board to consider the advisability of dispensing with the service of personal notices on landowners affected by town-planning schemes beyond article I. of the regulations, and of requiring all subsequent notices to be by public advertisement only.

"A.A. Smoker," and Exhibition.

A members' smoking concert and exhibition of half-inch scale drawings and photographs of recently executed work will be held at 18, Tufton Street, Westminster, on May 3rd. The exhibition will be opened by the President, Mr. Gerald C. Horsley, F.R.I.B.A., at 7.30 p.m., and the concert will commence at 8.30 p.m. The exhibition will remain open until May 11th.

CORRESPONDENCE.

The Editors disclaim all responsibility for the statements made or opinions expressed by correspondents. Correspondents are asked to be brief, and to write on one side only of the paper.

*The R.I.B.A. and Registration.
To the Editor of THE ARCHITECTS' AND BUILDERS' JOURNAL.*

SIR,—In reference to the letter from the Institute Members' Club which appeared in the Journal of the R.I.B.A. for April 13th, we should like to point out that the question of Registration with which it deals is one so profoundly affecting the welfare of the profession that it should not be allowed to die through the apathy or indifference of the responsible guardians of the trust and obligations imposed upon them by the general body of the Institute. Nobody regrets more than ourselves the futile efforts made by the R.I.B.A. to deal successfully with a great problem which is of vital interest to every practising architect. These futile efforts were the result of an adoption of a foolish compromise which satisfied neither side, and subsequent events have shown that the compact made five years ago was an unworkable one. In these circumstances we now feel free to take an independent course, and definitely and finally to throw over our allegiance to the policy of compromise then forced upon us, with which we have never pretended to be really in sympathy.

We consider that the R.I.B.A. scheme, even with any considerable modification of its details, could never become law; for it is ludicrous to suppose that any Government would permit the Institute to become the sole examining body for granting diplomas or allow it to have sole jurisdiction over the profession of which it forms so small a part. For instance, the University of Cambridge has inaugurated a School of Architecture and instituted examinations on a higher and more comprehensive scale than those of the Institute. Is it likely that this ancient seat of learning, one of the two oldest educational centres in the kingdom, with its two parliamentary representatives, would submit for one moment to the proposed dictatorship of the Institute?

Again, is it reasonable to assume that the University of Oxford, which will probably follow the sister University in founding a course of study in architecture, with its prestige, power, and influence behind it, will stultify a more than probable future educational extension by passively submitting to the philandering scheme of the Institute?

Surely, having regard to the fact that the policy of the R.I.B.A. is bound to bring about the active opposition of the distinguished parliamentary representatives of these universities, whose views on educational questions would be likely to be accepted by Parliament almost without question, there would be no chance of the Institute's Bill becoming law, unless the equitable recognition of these and other educational bodies were freely accorded.

As a melancholy example of the short-sighted policy of the Board of Architectural Education, whose action was subsequently confirmed by the Council, we may quote the case of Cambridge University.

Certain Universities of recent formation, and without parliamentary representatives, which have adopted the R.I.B.A. regulations in regard to architectural study, were regarded as "recognised schools," and, as such, obtained certain privileges—that is, exemption

from the Intermediate Examination, etc., whereas Cambridge, with a higher standard of education and powerful influence in both houses, was not accorded a similar exemption. The absurdity of this exclusion is more apparent when certain other facts are taken into consideration, such as the privileges accorded to Liverpool and Manchester, which were granted because these universities taught "design," whereas Cambridge does not pretend to do so.

The reason for excluding Cambridge is not quite clear, inasmuch as "design" is only an optional subject in the Intermediate Examination, and the confusion of ideas becomes absolutely chaotic when it is remembered that the leading opponents to Registration have declared over and over again that "design" cannot be taught, and therefore we should have thought could not become a subject for examination.

However, the question of education is one of far too serious a nature to be allowed to be treated thus lightly and illogically, consequently as a preliminary proceeding we think the Institute would be well advised to approach the older universities on the subject of architectural education in a far more friendly and conciliatory spirit than it has yet shown, with a view to enlisting their guidance and support. Further, it is folly for the Institute to imagine that it has the remotest chance of securing Parliamentary recognition for its members without due assurance that its proposals will not encounter active opposition of the Surveyors' and Engineers' Institutes, to say nothing of the many borough and county councils, all of which bodies will assuredly have to be placated.

In short, the Institute must remember that it is acting for the welfare of a large profession, of which it forms only a part, and not for the individual glorification of its members.

There is much spade-work to be done by the Institute before any Bill can be drafted; and if the R.I.B.A. would condescend to set about this preliminary work instead of forming itself into Committees to draft Bills which have no earthly chance of ever becoming the law of the land, the Council would be embarking on a course of profitable work. The continuance of its policy of spending its time, and irritating its more serious members, in futile efforts to obtain parliamentary recognition without first preparing the ground, seems to us to be nothing more nor less than trifling with a stupendous problem which has yet to be solved.

A. W. S. CROSS.

GEORGE HUBBARD.

Verona, April 21st.

*What to Do with the Crystal Palace.
To the Editor of THE ARCHITECTS' AND BUILDERS' JOURNAL.*

SIR,—I was glad to read the interesting leading article in your issue for April 17th on what might be done with the Crystal Palace, and particularly to see that you regard the proposal to utilise it and its grounds for the purposes of an open-air folk-museum as "the most definite proposal before the public." Some of your remarks, however, suggest that you do not fully appreciate the character which we who have made this proposal aim at giving to such an open-air folk-museum.

With your central idea that the Crystal Palace and its grounds should be made into a place of beauty, and with your belief that, if this be done, people will

again be attracted thither, I heartily concur. That, however, is precisely what we are aiming at, and your suggestion that the folk-museum might be secreted "in some part of the ground set apart for it, so as not to interfere with the general character" of the grounds "as a pleasure-ground" will come with no little shock to those who are familiar with open-air museums in other parts of the world. So far as the usual indoor museums in towns are concerned, you doubtless are quite correct in saying that people go there "when the weather is uninviting for outdoor enjoyment," but with the open-air museum as it exists in the three Scandinavian countries quite the contrary is the case. The enormous crowds who visit these museums on all days of public holiday certainly do not go with the object of studying any abstruse question of folk-lore; they go because they will see beautiful objects in beautiful surroundings, and they find the beauty no less because something of human interest is superadded to it.

To make the Crystal Palace "a palace of pleasure", and to provide for its visitors "pure enjoyment" is a worthy ambition, and has my hearty sympathy, but I would suggest that the highest pleasure and the purest enjoyment do after all demand some intellectual substratum. Curiously enough, I myself happen to have formed one of the crowd at Hampton Court on the day you mention, and I am quite sure, both from this and from many a previous experience, that a very large number of those who go there to enjoy the beauty of the flowers combine with the purely sensuous enjoyment an intelligent interest. To judge from the scraps of conversation one over hears, a large percentage of the visitors are themselves horticulturists in a small way. So, too, the visitors to the open-air museum of Skansen at Stockholm do not find their sense of its remarkable beauty impaired because it is intertwined with memories of the past, strikes back to the foundation of national art, and presents in a small compass the surroundings that have nurtured so many of Sweden's unforgotten dead.

In this country we should aim at the same high ideals, and I do not share your doubts that fitting architectural material would be forthcoming. But our scheme, as you are aware, extends far beyond this; it includes the preservation of all the arts and crafts and pastimes that truly belong to the nations of the United Kingdom. Our scheme, while retaining much with which the Crystal Palace is already associated, will have in addition that which, as you rightly say, the Palace lacks—a central idea; and this idea is one that should commend itself to every Briton at home and beyond the seas.

F. A. BATHER.

British Museum.

Instruction in Structural Mechanics.

A course of instruction in this subject is being given at the London County Council School of Arts and Crafts, Southampton Row, W.C., on Thursday evenings from 7 to 9.30 p.m., by Mr. Percy J. Waldram, F.S.I. This course has been specially designed in preparation for the entrance examination, intermediate and final, of the Royal Institute of British Architects; the board of Architectural Education of the Royal Institute having called attention to the necessity for more thorough knowledge of the subject of structural mechanics on the part of those seeking admission to the Institute.

THE COST OF BUILDING LABOUR.*

BY R. M. KEARNS, F.S.I.

One of the chief difficulties encountered by the quantity surveyor when preparing a schedule of prices for measured work, or an estimate priced in detail of the cost of a proposed new building, is that of making a just allowance for labour. It is with this difficulty that the present paper mainly deals.

LOOKING at a table of wages rates in the building industry throughout the kingdom, the author could not help feeling astonished at the low rates obtaining at the present time in some of the country towns and throughout Ireland; for on studying the figures it is found that, as a rule, the number of hours worked is greater in those localities where the lowest rates are paid.

As to the number of hours worked in summer and winter, the author thought that, for all practical purposes in connection with estimating, the following figures are sufficient:—

	Average number of hours worked per week per man. Summer. Winter (12 wks).	
London (all trades, excluding overtime) ..	50	45
Country (all trades, excluding overtime) ..	55	50

The following rates, the author said, are paid in London in connection with reinforced concrete work: Labourers 7d. per hour (a few at 7½d.); gangers—one to about thirty labourers—9d. to 10d. per hour; smiths, 10d.; carpenters erecting casings and centerings, 10½d.; and foremen carpenters, 1s. to 1s. 3d. per hour.

Lump-sum Contracts.

Building contractors and their foremen are splendid organisers and controllers

	Total Cost.	Cost of Labour shown in percentages of the Total Cost of the Building.
A.—Lump-sum contract for the erection of an ordinary brick building with stone dressings. Estimate based on carefully prepared Bills of Quantities and tendered in competition	£9,500	
Extras ..	£700	
Omissions ..	£200	
Net cost of Variations ..	£500	
	£10,000	(say) 40
B.—A similar building, measured in the course of erection, and valued on a Schedule of Competitive Prices. (There is usually more day work allowed in this form of Contract than in Form A) ..	£12,000	45 to 50
C.—A similar building, erected entirely as day work, all materials and labour being paid for in accordance with weekly vouchers. Labour rates and the prices of the principal items of materials embodied in the Contract ..	£15,000	55 to 60

*Extracts from a paper read at the Ordinary General Meeting of The Surveyors' Institution.

of labour; consequently the cost of erecting a building is reduced as nearly as possible to the minimum in the case of the lump-sum contract. The author referred, of course, to a contract based on an estimated amount of the cost of all labour and materials, such amount having being tendered in a bona-fide competition. On the other hand, the cost of erecting a building approaches the maximum when labour and materials are paid for as day work.

The table at foot of the first column will show at a glance the advantages of the lump-sum contract, and the approximate percentage of the cost of labour.

It will be noticed that the percentage of the cost of labour increases with the introduction of day work. Under Contract "A" the building owner receives the full benefit of the organising and energising abilities of the contractor. In the case, however, of Contract 'C,' it is not to the contractor's immediate advantage to push forward the work with the utmost vigour unless he is anxious to remove his plant. As a matter of fact, the longer the workmen are employed in day-work, and the greater their number, the larger is the contractor's profit, seeing that he receives a premium varying from about 3 to 15 per cent. on all wages paid in that connection. The table is, of course, theoretical, but the author was convinced that the figures could be supported by general experience.

A salient point in connection with the lump-sum contract is that the contractor, in the absence of any special arrangement to the contrary, stands to gain or lose on the amount of his estimate, no matter what fluctuations may take place in the wages rates of the workmen. In equity, however—putting aside the question as to what should happen in the case of a decrease—it would appear that some allowance should be made to the contractor when he is compelled to make a rise in wages under the force of circumstances which could not be foreseen before the date of his tender. This allowance would have to be arrived at by ascertaining in the first place the value of the measured work executed after the rise in wages takes effect, and then adding a percentage on the proportion of the cost of labour, differentiating between mechanics and labourers.

Proportionate Value of Labour and Materials.

In this matter every contract should

Trade.	Approximate Proportion of the Cost of Materials and Plant.	Approximate Proportion of the Cost of Labour.	
		Mechanics.	Labourers
	per cent.	per cent.	per cent.
Bricklayer ..	67	24	9
Mason ..	40	55	5
Slater ..	80	15	5
Carpenter ..	70	27	3
Joiner ..	37	62	1
Smith ..	80	15	5
Plumber ..	75	16	9
Plasterer ..	45	41	14
Glazier ..	85	15	—
Painter ..	40	56	4

of course be dealt with on its own merits, as the proportionate value of labour to materials and plant varies in each trade according to the nature of the materials and the architect's designs. The proportions shown at foot of second column might apply to ordinary public buildings or first-class residences.

Reinforced-concrete Construction.

In reinforced-concrete buildings the cost of labour is something between 50 and 60 per cent. of the total cost of the structural work, as compared with an approximate 40 per cent. in the case of ordinary brick and stone buildings. There is very little difference between the cost of the finished reinforced concrete and that of brickwork, bulk for bulk; and the great saving effected by building in reinforced concrete is, of course, due to the extraordinary thinness which is permissible in walls, piers, etc.

Fair Wages Clause.

As to the responsibility for the payment of fair wages, I may refer here to a circular which was issued to various Councils in September last by the Local Government Board, setting forth the clauses recommended for general use in Government contracts by the Fair Wages Advisory Committee. Quoting from the circular: "It appears to the Board that the policy adopted in the case of Government contracts should be followed in the cases of all contracts for the execution of works, or the supply of materials, which are entered into by Local Authorities, or by or on behalf of any committee wholly or in part appointed by a Local Authority. Whilst they are aware that many Local Authorities specify in their contracts conditions to be observed by the contractor as to rates of wages and other matters affecting persons employed by him, the Board think that in every case the Authority should give the matter careful consideration, with the view to the introduction in the contracts of clauses on the lines of those inserted in Government contracts."

Of the clauses referred to, the following is the most important:—

"The contractors shall in the execution of this contract observe and fulfil the obligations upon contractors specified in the Resolution passed by the House of Commons on the 10th March, 1909—namely, 'The contractor shall . . . pay rates of wages and observe hours of labour not less favourable than those commonly recognised by employers and trade societies (or in the absence of such recognised wages and hours those which in practice prevail amongst good employers) in the trade in the district where the work is carried out. Where there are no such wages and hours recognised or prevailing in the district, those recognised or prevailing in the nearest district in which the general industrial circumstances are similar shall be adopted. Further, the conditions of employment generally accepted in the district in the trade concerned shall be taken into account in considering how far the terms of the Fair Wages Clauses are being observed. The contractor shall be prohibited from transferring or assigning directly or indirectly to any person or persons whatever any portion of his contract without the written permission of the Department. Subletting, other than that which may be customary in the trade concerned, shall be prohibited. The contractor shall be responsible for the observance of the Fair Wages Clauses by the sub-contractor.'"

Schedule of Labour Rates.

A schedule of labour rates should be attached to every form of contract, the rates named being those which must be actually paid by the contractor. In the case of a lump-sum contract the schedule of labour rates to be allowed to the contractor for labour in day work on extra works should contain a clause of the following description :—" The above rates are those which are understood to be the standard rates of wages appertaining to the various trades in , and to be actually paid to the men employed. An allowance of per cent. will be made to the contractor upon the actual rates paid to the men, to cover profit, superintendence, and the use of all tools, sharps, scaffolding, etc. In the event of any changes being made in the wages of the workmen during the continuance of the contract, corresponding changes will be made in these rates."

In many cases the rates can be verified by applying to the Master Builders' Federation or to the surveyor to the local authority of the district concerned.

The following comparative statement (taken from *London Statistics*, vol. xxi., issued by the London County Council) shows the weekly wages and hours of labour in certain trades in London, Paris, Berlin, and Brussels :—

TRADE.	LONDON (1906).		PARIS (1905).		BERLIN (1905).		BRUSSELS (1908).	
	Wages. per week.	Hours per week.	Wages per week.	Hours per week.	Wages per week.	Hours per week.	Wages per week.	Hours per week.
Bricklayers	43/9	50	38/5	60	39/1	53½	23/9—27/7	66—69
Carpenters	43/9	50	43/2	60	39/1	53½	25/4—28/8	66—69
Joiners	43/9	50	38/5	60	31/11	52	23/9—29/0	66—69

Works of Maintenance.

In a properly conducted maintenance contract the expenditure incurred over several years should show the cost of measured work and day work in something like the following proportions :—

Measured work, covering materials and all labour	65 per cent. of the total expenditure.
Day work (in jobbing repairs)	Labour 25 per cent. of the total expenditure. Materials 10 per cent. of the total expenditure.

Here again my mission is to point out that day work, although inevitable, should be restricted as much as possible, and in no instance should the cost be allowed to exceed 50 per cent. of the average annual expenditure. A case was recently brought to my notice in which various works of maintenance were carried out for a certain department under a schedule at a cost of about £4,400, and of this total the day work charges did not amount to 5 per cent. No doubt this is an unusually low percentage, but it shows what may be done under proper management.

Measured Work and Day Work.

It is obvious that in measured work which is paid for at schedule prices covering the cost of all materials and labour, the contractor's foreman, if he wants to

show a profit, must hustle the workmen and contrive to finish the job at the least possible cost to his employer. The desire to do everything as day work can therefore be understood. Day work calls for no measuring on the part of the surveyor, and ensures peace and quietness for both sides, the employers and employed. The only drawback is the extra cost. Experience proves, however, that this extra cost is a serious item; indeed, it may be taken as a well-attested fact that decorative works, repairs and alterations, connected with a maintenance contract, cost from 50 to 100 per cent. more if executed as day work instead of measured work. I am told, however, that it is possible to get work executed as cheaply by day work as by measured work; and I admit that it is possible, but only if the day work were performed by a picked group of conscientious men, properly supervised, and that the prices for "materials" were in correct proportion to the prices for "materials and labour in fixing." The possibility is, however, somewhat remote, especially in connection with large contracts carried out for public bodies; for it is well known that men do not work so strenuously for the latter as for private individuals. The work of supervision, after all, is the secret

is widely out of proportion to the amount of materials supplied, there is need for investigation.

(2) When examining the weekly vouchers, note the names of the workmen and the total number of hours charged per day in respect of each man. In this connection see that no more men are employed than the proper number required to do the work, foremen being apt to crowd workmen on to day work. In the absence of special arrangements, any claims in respect of contractor's foremen should be disallowed, except in cases where the foremen actually work as mechanics.

(3) See that the materials charged for are not in excess of what was required for the work. For instance, in setting ranges requiring a supply of, say, 50 bricks, a surveyor would be quick to make an adjustment if 500 bricks were charged for in error. Again, in plumber's work the quantity of solder charged for should bear a reasonable proportion to the soldered joints, etc., found in the work.

(4) See that there are no items in the day work accounts which are also charged for in the measured work accounts. In large contracts such items may often be found. They creep in, to put it generously more by accident than design. Stone, landings or sills, joists, floor-boarding,

of economy in all building operations so far as labour is concerned.

Examination of Contractors' Accounts.

The proper examination of the contractors' accounts is highly necessary if the expenditure on works of maintenance carried out for public bodies is to be controlled and kept within the required limits. For instance, the examination of day work accounts should not be relegated to a man with no more professional experience than that of an office boy or pupil, but should be examined, in conjunction with the measured work accounts, by a surveyor of ripe experience and possessing the highest technical qualifications. Further, in all cases where works are carried out partly as "measured" and partly as "day work," the whole of the accounts should be checked, or at least carefully scrutinised by the surveyor who has been entrusted with the "measuring up" and who has gained in the process of measuring a full knowledge of the work as actually executed.

Efficient examination will reduce expenditure, while inefficient examination, which is always quickly recognised by the contractors, will increase it.

For the benefit of some of the junior members of the profession, I venture to name the following rules which should be borne in mind when examining day work accounts :—

(1) Watch the proportion of charges for labour and materials. In the labour

slate-shelving, glass, and other items, which, according to particular circumstances may be passed either in day work or measured work accounts, are sometimes claimed in both. "Labour in fixing" and "preparatory labours" in decorative work, may also be found to be charged for in duplicate. On one occasion, when examining accounts for decorative work I found that the amount of labour charged for as day work under the heading of "repairing and bringing forward at damaged places, etc," was, according to a liberal estimate, sufficient to do the whole of the preparatory and finishing work which was charged for in the "measured" account. In this case only a small quantity of day work should have been charged for in respect of repairs.

(5) See that ample descriptions of the work done by the different men employed in day work are given on the weekly vouchers.

(6) Obtain separate vouchers and accounts in connection with all special works, in order that the cost may be compared with the estimated amounts.

(7) In checking the prices of items which are not in the schedule, do not be influenced by "sporting charges." For instance, if 1s. per ft. run or super. is a reasonable or "pro rata" charge, do not pass 3s. per ft. in the event of the contractor having charged 5s. To allow more than 1s. per ft. in a case like this would display weakness and incompetence.

Although in following such rules as the foregoing the total amount of any particular batch of accounts may not be reduced to any large extent, the moral force of the surveyor's queries and investigations would be very far-reaching, and of inestimable value to his employers.

Bearing an important connection with the cost of labour, it should be noted that under clauses already referred to in the case of the erection of a new building, the maintenance contractor should take all risks and responsibilities in regard to damage to property or injuries to workmen in connection with "measured" or "day work"; and also undertake to pay "such wages as are generally accepted as current in each trade for competent workmen."

The actual labour rates paid should be shown on all day work vouchers on which, as before described, a percentage should be allowed to the contractor, covering profit, superintendence, and the use of all tools, sharps, scaffolding, plant, etc. This system is preferable to that in which the rates shown on the vouchers and bills are inclusive of profit, and furnish no direct evidence as to the amounts actually paid to the different workmen.

The following are the current rates paid to non-building workmen employed in connection with the maintenance of buildings in London:—

	Rate per hour actually paid to the workmen, so far as can be ascertained.
Faviours	8½d. to 10d.
Rammermen	8d.
Engineers or Fitters attending to heating, ventilating, and cooking apparatus, and to fire-extinguishing apparatus	8½d. to 10½d.
Assistants do. do. ..	6d. to 7d.
Stokers	7d. to 9d.
Engineers attending to lifts ..	8½d. to 10½d.
Assistants do. do. ..	6d. to 7½d.
Electricians attending to electric bells, etc.	9½d.
Electric fitters and wiremen ..	9d. to 9½d.
Wiremen's labourers	7d. to 7½d.

The complex functions of the engineering trades are beyond the scope of his paper, and I can merely express the opinion that money is well spent in the payment of good wages in order to secure thoroughly reliable men in connection with the heating and lighting of any large blocks of buildings. The duties all for the exercise of much special skill and zeal. A really good stoker, for example, will economise in fuel and yet obtain the required heating power from his furnace. Details as to working hours, overtime, out-door allowances, etc., will be found in the "By-laws and regulations" of the Amalgamated Society of Engineers, 110, Peckham Road, S.E., and the "National Agreement as to Working Rules and Conditions," issued by the National Association of Master Heating and Domestic Engineers, 12, Great James Street, Bedford Row, W.C. Particulars as to the working rules, etc., of the electrical trades may be obtained from the head office of the Electrical Trades Union, 26, Cannon Street, Manchester, and from the Electrical Contractors' Association, 20, Bucklersbury, E.C.

Labour Efficiency.

In no way is the cost of labour affected much as by the efficiency or inefficiency of the workmen. While there are plenty of efficient men to meet all ordinary requirements, it seems to be the fact that a percentage of inefficient men in the

labour market is steadily increasing. This is no doubt largely due to the gradual collapse of the old-fashioned system of apprenticeship, and to the ease with which men can get enrolled as craftsmen in some of the trade unions.

The London County Council has for many years been taking an important part in promoting the efficiency of workmen. Schools of building have been established in Brixton and Dalston Lane which promise to be of great benefit to young men, as they can there receive practical teaching under somewhat similar conditions to those met with on buildings or in builders' shops. I have seen it stated, however, that a large percentage of the students who attend these classes do not eventually enter the building trades, but become clerks. If the statement be true, all one can say is that these clerks will be none the worse for possessing some technical knowledge, if it be only of tools, and the method of using them.

Overtime.

Overtime is well known to be detrimental to the health and energy of workmen, and whether in connection with measured or day work should only be countenanced in cases of most exceptional urgency. It is an expensive form of labour on account of the difficulty and extra cost involved in supervision, and by reason of the fact that the workmen's wages rates are increased from 25 to 100 per cent., according to a scale, in respect of the hours worked after the ordinary leaving-off time. Where the work has to be continued day and night the trade unions prefer that night gangs should be employed. This arrangement is a great improvement on the overtime system, although it does not dispose of the difficulties as to supervision. It should be noted that mechanics and labourers employed in night gangs received 1d. per hour and painters 2d. per hour in addition to the ordinary rates of wages.

Piecework.

With reference to piecework it is generally found that when men are engaged on such work they can earn more than they would receive for labour paid for at the trade union or current rates of the district; and as a rule good and expeditious work is done, the men having reason to be satisfied with the payment they receive for it. Piece-work, however, is injurious to the health of workmen.

CONCRETE WITH TIMBER REINFORCEMENT.

In a paper on "Ligno-concrete," read before the Society of Engineers, Mr. Gerald O. Case described some investigations undertaken with the object of ascertaining whether it was possible to reinforce concrete with timber rods.

The paper described experiments made to ascertain (a) the amount of water absorbed by 18 kinds of timber immersed in fresh water, along the grain and through the end grain respectively; (b) the relative absorption by the timber of fresh and sea water in the same period; (c) the relative amount of water absorbed by timber embedded in 6 to 1 concrete and neat cement blocks; (d) the effect of applying wood preservative, creosote, varnish, etc., to the timber before insertion in the concrete or cement blocks; (e) the effect on the adhesion between the timber and the concrete of soaking the rods before insertion. Examples were

given to show that concrete effectively preserved timber embedded in it.

During 1910 tests were made of a number of ligno-concrete and plain concrete beams 4½ by 4½ by 55 in. long at the Brighton Municipal Technical College. The beams were made on the cliffs at Rottingdean in timber moulds, four being made at a time from the same gauging of concrete, which was composed of one part granite chips, ½ part fine sand and ½ part coarse sea sand, and ½ part cement. For some of the beams fine beach sand was used instead of granite chips. The reinforcing rods had a number of nails driven into the wood which projected ½ in. The reinforcing frames with the exception of one made with teak rods were soaked in water for two or three days before being put into the concrete, and the beams were all loaded in the centre. The span was 42 in. The load which produced the first crack in a beam reinforced with ¾ in. jarrah rods was 850 lb., and the maximum load at which the rods broke was 3,300 lb.; with tallow-wood rods these figures were 1,050 lb. and 3,150 lb., while in the case of rods made of teak, deal, oak, ash, and mahogany the figures ranged from 1,400 lb. to 1,000 lb. and from 2,500 lb. to 1,595 lb. respectively. The age of the beams varied from six to 14 days.

Twelve ligno-concrete beams, 8 in. deep by 4 in. wide and 4 ft. 6 in. long, reinforced with oak and yellow deal rods, and one plain concrete beam, were tested for the author by Professor C. A. M. Smith, of East London College. The beams were made with concrete of the proportions used for the small beams. They were loaded in the centre, the span being 4 ft., and readings were taken on the deflection of the beam for each load, the load being then removed, and the amount of permanent set noted. The beams reinforced with oak took an ultimate load of 1 to 1.4 ton at the centre; the load at yield point was 0.42 to 0.40 ton, and the deflection at that point was 0.005 to 0.024 in. In the case of the deal reinforcement the figures were 1.2 to 2.0 tons, and 0.6 to 0.7 ton, and 0.01 to 0.017 ton respectively. The age of the beams ranged from 62 to 120 days.

In the author's opinion, ligno-concrete could not compete with ferro-concrete for purposes where more than about 1.2 per cent. of steel reinforcement was required, because the size of the timber would be too large for convenient use, but he thought that there was a large field for it in the construction of bungalows, buildings for small holdings, floors, piles, posts, fencing, coast and river work, etc. It had already been used for making fence posts from the author's designs. The cost worked out at about 2.1s. per foot cube, or about 20 per cent. cheaper than creosoted yellow deal and 40 per cent. cheaper than English oak. In Canada, as a result of the author's investigations, the Pacific Coast Construction Company of Victoria, British Columbia, had formed a special ligno-concrete department, and had made a large number of slabs for houses. They had built four houses, and at the present time had contracts in hand for over 20 others of the bungalow type, all of which were to be built with ligno-concrete slabs. The slabs were made to a standard size, 8 ft. by 2 ft. by 3 in., or 1½ in. thick. If they were made 1½ in. thick, two of them were used to form a hollow wall. No slabs had shown the slightest signs of cracking, although they were transported by rail three weeks after they had been cast.

NEWS ITEMS.

Birmingham Blue Coat School.

As the Governors have decided to seek a more suitable site for this school, architects taking part in this competition have been advised not to proceed with the drawings until further notice.

A Convalescent Home.

A convalescent home for women at Swithland, Leicestershire, which has been recently completed and opened, has been erected at a cost of £17,000. Messrs. Seale and Riley are the architects.

Plasterwork and Interior Decoration in the Students' Union, Liverpool.

Professor Reilly, of the Liverpool School of Architecture, has placed with Messrs. John Tanner and Son, of Liverpool and London, the whole of the fibrous plaster and "Ferrocon" imitation stone work for the new Gilmour Hall in the Students' Union, Liverpool, to be carried out in the Neo-Grec style of the interior.

The Windsor Memorial to King Edward.

The Windsor Memorial to King Edward, which was unveiled by Prince Christian on behalf of his Majesty on Monday, consists of a bronze statue of the late King, standing on a stone pedestal with bronze decorations. At the four corners are allegorical figures in bronze holding shields. The statue has been executed by Countess Feodora Gleichen, whose design was chosen from among those of about 18 competitors.

Professor Capper Resigns the Manchester University Chair of Architecture.

The Chair of Architecture in Manchester University has become vacant by the resignation of Professor Stewart H. Capper, M.A., F.S.A., A.R.I.B.A. Professor Capper some time ago met with a riding accident. Pneumonia supervened, and, acting under medical advice, Professor Capper has, to the great regret of all, resigned the chair which he has so long filled with conspicuous ability and success. All will wish him a speedy restoration to full health and activity.

Warming and Ventilating Installations.

Messrs. E. H. Shorland and Brother, Ltd., warming and ventilating engineers, Failsworth, Manchester, report the following installations:—Catholic Cathedral Schools, Plymouth: warm-air ventilating patent Manchester grates and inlet ventilators. Wycliffe Memorial Church and Schools, Preston, Horden Church, Co. Durham, and new schools at Wakefield: patent exhaust roof ventilators. Additions to Farnham Workhouse: patent Manchester grates. Hospital, Riverton, New Zealand: double-fronted patent Manchester stoves, with descending smoke flues. Houghall new infectious hospital, Durham: warm-air ventilating patent Manchester stoves.

National Nautical School, Somersetshire.

The King has expressed his regret that he cannot visit Portishead next month, when the chapel of the National Nautical School is to be dedicated by the Bishop of Bath and Wells. He will be represented on May 14th by H.S.H. Prince Louis of Battenberg. H.R.H. Princess Henry of Battenberg laid the foundation stone of the school buildings some years ago, and H.R.H. Princess Christian

visited Portishead when the school was opened. The school is beautifully situated on the shore of the Bristol Channel. It was built from the designs of Mr. Edward Gabriel (Edmeston and Gabriel), who has also designed the chapel, which is now nearing completion. Messrs. Cowlin and Sons, of Bristol, were the contractors for the school buildings, and Messrs. Samuel Martin and Sons for the chapel.

Delhi Town Planning.

The Government of India are considering the details of the Delhi arrangements, and the Delhi Town Planning Bill will be prepared and taken up during the autumn session of the Legislative Council. There are also possibilities of subsidiary legislation for the Imperial capital. Mr. Brodie, Mr. Lutyens, and Captain Swinton were expected to be in Delhi by April 15th. There are several Town Planning Acts, which the Government may utilise as a guide, particularly the recent ones which deal with this subject in the Philippines and also the Bombay Government Town Planning Legislation. The Bill, it is expected, will be introduced and passed by the end of September.

New Western Approach to London.

The Middlesex County Council last week adopted a series of recommendations presented by the Highways Committee approving of the proposed western approach road to London. It was suggested that in the first instance it should be dealt with by the London and Middlesex County Councils and the Road Board, the question of the contributions of the local authorities concerned being left to the Middlesex Council and the authorities. The scheme is to cost £1,750,000, of which £1,000,000 is applicable to London, and the Road Board is contributing £875,000. The committee thought that, as the new road is properly speaking, a national one, the Road Board should contribute a larger sum.

Incorporated Church Building Society's Grants.

At its usual monthly meeting, held on April 25th, at the Society's House, 7, Dean's Yard, Westminster Abbey, the Hon. Sir E. P. Thesiger, K.C.B., in the chair, grants of money were made in aid of the following objects:—Building new churches at Belfield, S. Ann, Rochdale, £100; and West Fordington, S. Mary, Dorset, £150, with smaller grants, ranging from £20 to £60, to churches at Eastrop, Lincoln, Gillingham, Notts, Derbyshire, Motttingham, and Essex. Four grants were also paid for works completed. In addition the sum of £250 was paid towards the repairs of various churches from trust funds held by the Society. The Annual General Court will be held at 3 p.m. in the Church House, Westminster, on May 23rd, the Bishop of Chester presiding.

Building Stone Made from Blast-Furnace Slag.

The manufacture of building stone from blast-furnace slag is an industry which is now assuming considerable importance in Germany. The process is not patented, and is very simple in details. Practically all blast furnace slag is suitable for stone making, but it must be in a granulated state. After it has been allowed to harden it is unsuitable. All attempts to utilise slag that has been crushed or ground, after having once

hardened, have failed to produce a good solid stone. The slag is granulated by the addition of water as it flows hot from the furnace. The granulated slag after being thoroughly mixed with the required proportion of lime is allowed to stand overnight before being put through the press. After being pressed the stones are stacked in the open air, and, after three or four weeks, according to the weather, they are ready for use. Under low temperature they harden slowly. If subjected to frost before thoroughly hardening they are crumbled and destroyed. Operations may, however, be continued in winter, the stones being hardened in steam-heated drying rooms. These stones grow constantly harder with time.

Architectural Studies at Cambridge University.

The General Board of Studies of Cambridge University recommends that a Board of Architectural Studies be established in the University. It is proposed that the Board should consist of the Vice-Chancellor, the Disney Professor of Archaeology, the Slade Professor of Fine Art, the Professor of Mechanism and Applied Mechanics, the Reader in Classical Archaeology, four members of the Senate elected by the Senate on the nomination of the Council, each of whom should serve for four years, together with two additional members nominated by the Board in the Lent Term of each year. The duty of the Board will be to organise the teaching of architectural subjects in the University, to draw up lecture lists, to include in the lists of lectures published by the General Board of Studies, and to admit students to courses of research in architecture.

The Shrine of the Sacred Heart.

By the completion of the mosaic in the shrine of the Sacred Heart at Westminster Cathedral one is able to gain a better idea than any of the other chapels of the scheme for mosaic decoration for the rest of the building. In accordance with Byzantine tradition, the walls are plated with cool marbles, white and green, while the vaulting is encrusted with vitreous mosaic, chiefly gold and blue. The statue occupies a niche at the top of the shrine, and in front is a large altar with a bas-relief of St. Michael. The statue, which cost over £300, is the gift of the English communities of the Sisters of the Sacred Heart. At the opposite end of the shrine, just under the vault, is a representation of the Sacred Heart in mosaic by the late W. C. Symons; it is the gift of Mrs. Murray. A silver lamp specially designed for Sir Paston Cooper is suspended from the vaulting in front of the statue, and from the silver-plated beams fixed across the shrine at the spring of the vaulting depend electric lamps, silver-plated like the beads. Most of the work for this shrine has been subscribed for by past students of the Sacred Heart nuns and by Catholics generally throughout the Empire.

Port of London Authority's New Office.

Details of the great scheme for providing a fitting home for the Port of London Authority have now become available. A three-acre site has been acquired in the City, forming practically the whole of the area bounded by Seething Lane, Trinity Square, Gt. Tower Street, Crutched Friars, and Savage Gardens. The block of buildings will be next door to Trinity House, and the main entrance

THE NEW HONG-KONG UNIVERSITY. LEIGH AND ORANGE, ARCHITECTS.

will face the Tower. The cost of the freehold is said to have been little short of a million sterling, and nearly a thousand tenants will have to find fresh quarters. Both old and new buildings will be concerned in the demolition. Muscovy House, a block of 150 offices, will come down, and—unless arrangements can be made for incorporation in the new building—the last of the Crutched Friars' Monastery, a fragment of the cloisters, must be swept away. Some of the houses in Savage Gardens are oak-panelled, and of great age. Only two buildings—Mark Lane Station and the offices of the Great Steam Navigation Company in Great Tower Street—will be left standing out of 62 on the island site. The clearance is believed to be the largest ever made in London for the purpose of erecting one set of public offices.

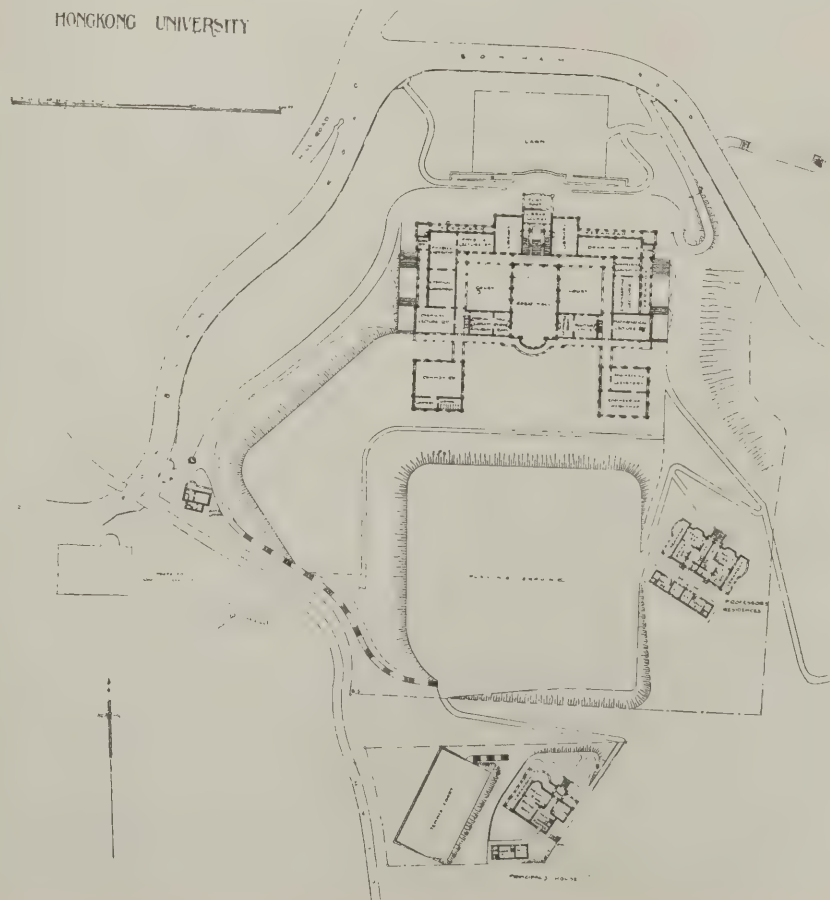

reinforced with Expanded Metal and finished with teak or English tiles. All the woodwork is teak.

The cost of the formation of site and erection of buildings has been \$350,000.00. (about £30,000).

The architects are Messrs. Leigh and Orange, of Hong-Kong, the present members of that firm being Mr. A. H. Ough, F.R.I.B.A., M.Inst.C.E., Mr. Alfred Bryer, and Mr. A. E. Griffin, M.Inst.C.E., and the contractor is Yik Loong.

THE HONG-KONG UNIVERSITY.

The Hong-Kong University was begun on April 20th, 1910, and opened on March 11th, 1912, by H.E. Sir F. Lugard, Governor of Hong-Kong. The site was given by the Colonial Government, and the building by the late Sir Hormusjee Mody. The buildings provide accommodation for 500 students, and are capable of extension. The chief feature is the great hall, 80 ft. by 50 ft., and 43 ft. high, with foyer, flanked by courts, around which are arranged on two floors, eleven classrooms, eight laboratories and workshops, libraries, common room, committee-room, principals' rooms, and offices. In the basement are cloakrooms, lavatories, and servants' quarters. Detached principal's house and professors' houses are finished, and a school of anatomy and residential blocks are in progress. The materials used are local red bricks, with local grey granite and Amoy red brick dressings. The floors are of concrete

MR. E. P. WELLS ON RE-
INFORCED CONCRETE.

A lecture on the subject of reinforced concrete was delivered by Mr. E. P. Wells, J.P., Concrete Institute, on March 18th, at the London County Council School of Building, Ferndale Road, Brixton, S.W., when over one hundred persons were present. A subsequent demonstration was given in the Mechanics Laboratory of a new piece of apparatus which had been designed by the Assistant Principal of the School, Mr. Arthur R. Sage, and Mr. A. E. Everett, for the determination of the Modulus of Elasticity of concrete, which machine is being used in connection with the class instruction in the theory and practice of reinforced-concrete construction given by Mr. H. Kempton Dyson, secretary of the Concrete Institute, and assistants.

The following is a summary of Mr. Wells's lecture, in connection with which 43 lantern slides were shown:—The practical side of reinforced concrete, Mr. Wells contended, was of the utmost importance in view of the poor quality of workmanship ordinarily employed.

The increase in the use of reinforced concrete, since 1900, has been greatly due to the fact that architects, engineers, and others had become convinced of the possibilities of the material. It had been proved to be more economical than steel-frame construction used in buildings, in some cases a saving from 15 to 20 per cent. being effected.

The design of reinforced concrete opened out a great field for efficient instruction therein, which the London County Council School of Building was giving.

In reference to drawings, the lecturer advised the use of single lines varying in thickness, for showing the reinforcement, the advantages being in preventing confusion in being more quickly seen, in not tiring the eyes so readily as two lines, and in saving time.

Referring to materials, he stated that cement should be kept free from dampness, cold or damp air, and stored in airtight bins, and that it should be tested directly it was delivered on the site of the works, and then, if quick use was required, three-day tests should be made. For soundness the Chatelier tests were sufficient.

An instance was referred to of some church foundations where, the cement having been hydrated before use, the concrete showed dampness throughout its entire length, and was easier to excavate after being down 20 years than the clay underneath it. The present-day cement was more liable to hydration than that of 12 to 15 years ago, owing to its greater fineness.

The sand used in concrete should be absolutely clean, and free from dirt, and the grains should not be the same size; this would result in the concrete being more homogeneous, impervious to moisture, and stronger.

Great care should be exercised in the selection of the water, which should be thoroughly clean and free from vegetable matter and salts that are deleterious to concrete; salt water itself did no harm, but it was advisable not to use it owing to its hygroscopic nature. The steel employed should conform to the British Engineering Standards Committee's Specification, and tests should always be made periodically to ensure that the quality did not fall off.

It was advisable to have cubes of concrete made on a job and to test them whatever the time of the year, keeping one set under laboratory conditions and another under the same conditions as those under which the work was carried out. That would form a gauge as to when the concrete on the works reached the strength required to take up the stresses for which it was designed so that it should be known when it was safe to remove the centering.

The centering should not be made of light material, otherwise on removal it might be found that the sides would have bulged out and settlement taken place throughout the work. This was not only ugly, but required extra expense in plastering. Centering should be so constructed that it could be removed easily without having to cut out the timber. In some cases it was more costly to pull down than to put up. The area of the base plates under struts should be sufficient to carry all the loads on them, or else settlement would occur, which would probably result in large shear cracks in the beams over the supports and destruction of the adhesion between the steel and concrete.

Once concrete was put into place, it should on no account be disturbed. The centering should be left up for a minimum period of three weeks, except for floor slabs and the sides of beams, which might be removed within seven days, but should the compression tests disclose a low crushing then the centering should be left in place from 4 to 6 weeks, or even longer.

Efficient superintendents were essential if the work was to be carried out in the manner designed. Lack of attention in this direction often resulted in serious accidents.

Referring to the placing of steel, the lecturer had sometimes employed small concrete blocks, slightly dovetailed in section and lightly reinforced, which were laid at the bottom of the beam casing, thus ensuring that the rods were the proper distance from the bottom and sides of the boxes and preventing any displacement from the calculated positions required.

The concrete should be of a wet nature, to enable it to flow readily round the reinforcement and to do away with excessive ramming and liability of damage to the reinforcement. An advantage of using dry concrete was that it attained its maximum strength at a much earlier period than that of a wet nature, but at the same time oxidation of the steel might set in, due to the concrete being too porous, and also the adhesion in most cases would be weakened.

If on removing centering large aggregate were found on the surface with an insufficient amount of sand, then such portions should be covered with a wash of cement grout, and a one to one sand and cement mortar forced into the interstices and finished off with a wooden float.

A mistake as regards floor finishing with granite or granolithic was to adopt too high a finish for the work, the consequence being that the initial set was broken up before the surface was completely finished. The remedy was to once trowel the floor and then leave it. But if a smooth surface were required it should be rubbed over with holystone and sand.

After the whole works were completed, final testing by loading over at least two bays to an excess of 50 per cent. beyond that for which it was designed was often done. If the work had been carried out efficiently, then the deflection of the floor

noticed should, after the load had been taken off, be entirely recovered and return to its normal state.

Mr. H. Kempton Dyson, lecturer on Reinforced Concrete and Structural Engineering at the School, in proposing a vote of thanks, stated that the course of instruction given was one of the most complete in the world, and that the London County Council School of Building was first and foremost in devoting great attention to the practical side by means of lectures and workshop practice, and without such practical study designers of reinforced concrete could not be thoroughly efficient.

BOOKS.

A French Manual of Reinforced Concrete.

French scientific and technical treatises are universally commended for their clearness of exposition, which is commonly attributed to the extreme neatness and precision of the language. On the other hand, it is sometimes complained that the quality of simplicity is overdone—that French text-books are apt to contain, in elaborate detail, much rudimentary matter that might well be taken for granted, or at least dismissed without labouring the point. Much, however, depends on the subject. An elementary treatise on reinforced concrete can hardly be too simple, or, within its scope, too comprehensive, and M. Salembier may therefore be held blameless for the thoroughness with which he has expounded the rudiments of the subject, and he is to be congratulated on his adherence to the tradition of lucidity to which he is heir.

The author begins with Tedesco's definition of reinforced concrete: "Concrete reinforced with bars of iron or of steel so that the combined resistance of these two materials serves effectually to support the loads, the metal being entirely surrounded by concrete." Then follows a very brief sketch of the history of the system, in which it is recalled, not without a touch of legitimate patriotic pride, that "reinforced concrete had its birth in France. It was a Frenchman—Joseph Monier—who, in the second half of the nineteenth century, first employed the combination of concrete and iron, materials which comprise between them the necessary properties for resisting tension and compression." Another Frenchman, M. Fr. Coignet, foresaw, about 1861, the possibilities of reinforced concrete; and a French marine engineer, M. Mazas, formulated, in 1876-77, the first bases of calculation for the new process of construction.

The advantages of reinforced concrete, as set forth by M. Salembier, are familiar enough, but the leading points may nevertheless be usefully repeated. Briefly they are as follows: The material is in the highest degree incombustible, and is therefore particularly suitable for the construction of theatres and other places of assembly, ensuring as far as possible the safety of human life by preventing and resisting outbreaks of fire, and in the same way affording the utmost security for the precious collections that are housed in museums and art galleries. Reinforced-concrete columns, it is again asserted, offer an appreciable advantage over unprotected iron columns, which, under the influence of fire, may either become contorted and tumble down, or, by mere expansion, may ruin the structure they were designed to support.

On the other hand, concrete, being a bad conductor of heat, offers effectual resistance, suffers but little damage in itself, and does none to its surroundings. The great strength relative to the comparative thinness of section of the walls, and their monolithic solidity, renders the material economical for large buildings; the cantilevering it makes possible prevents obstruction and saves valuable space; and M. Salembier lays stress on its hygienic value for the construction of hospitals, schools, and similar institutions, because it is not subject to decay, does not harbour disease germs, and is innocuous to vermin. The author's claim that, being a plastic material, it readily lends itself to decorative treatment, is one that may easily be pushed too far. Ornamentation is perhaps more possible than desirable in the kinds of buildings to which reinforced concrete seems most appropriate; and if the designers continue to give us buildings in which fitness, harmony, and proportion are duly observed, the question of decorative detail may be dismissed with the suggestion that reinforced concrete is "when unadorned adorned the most." M. Salembier's manual, which contains ninety useful diagrams, is published at Paris by Dunod et Pinat, 47 and 49, Quai des Grands-Augustins. In the section on materials, the name of the inventor of Portland cement (Joseph Aspdin) is misprinted 'Aspdier.'

An Elementary Manual of Reinforced Concrete.

In producing "Elementary Principles of Reinforced Concrete Construction," the author's aim was to meet the demand for an inexpensive book, written from an elementary standpoint in an explanatory manner, without the use of advanced mathematics, but at the same time in accordance with the best accepted theory. His method consists in explaining the theory of each problem, and illustrating it by worked examples. In a preliminary note on the economy of reinforced concrete, the case is thus stated: "Roughly speaking, steel costs volume for volume about fifty times as much as concrete. Steel is about thirty times as strong as concrete in compression, and three hundred times as strong in tension; so that to carry a given load in compression the cost of concrete will be about three-fifths that of steel, while for tension the cost of concrete will be about six times that of steel. In a structure, therefore, in which some portions are subjected to compression and some to tension, we can get by a scientific combination of steel and concrete a more economical result than would be obtained with either material alone." Unlike M. Salembier, who, as noted above, claims the invention of reinforced concrete for M. Monier, Mr. Andrews gives precedence to an Englishman, Mr. W. B. Wilkinson, of Newcastle-on-Tyne, who in 1854 took out a patent for fire-resisting construction in which the fundamental principles of modern reinforced-concrete construction are embodied. The expository portion of the book, which seems, on a cursory examination, to be well and thoroughly done, is followed by a chapter in which the leading systems of reinforced concrete are described and illustrated; and the book forms an easily graded and altogether convenient approach to a subject that grows daily in importance, and of which complete ignorance is no longer excusable, seeing that treatises on it are now plentiful and are becoming cheap. The notation adopted through-

out is that put forward by the Concrete Institute. One or two very slight misprints leap to the eye, such as the misprint of the late L. G. Mouchel's name on p. 154, the use of an acute instead of a grave accent in the name of M. Considère, and the omission of the cedilla from François.

Elementary Principles of Reinforced Concrete Construction. A Text book for the use of Students, Engineers, Architects, and Builders. By Ewart S. Andrews, B.Sc.Eng. (London). With numerous illustrations and worked examples. London: Scott, Greenwood and Sons, 8, Broadway, Ludgate, E.C. Pages xii. + 196, 7½ins. by 4½ins., price 3s. net.

CONCRETE FOR GREENHOUSES.

Concrete is rapidly superseding wood in greenhouse construction. The conditions, both inside and outside a greenhouse, are very unfavourable to woodwork, of which the very best yields quickly to the influences of heat and moisture to which it is continually subjected. A method of protecting the timber with concrete is, it is stated, proving very satisfactory at the extensive greenhouses of the Poehlmann Brothers Co., Morton Grove, Illinois, which cover approximately thirty-seven acres.

The greenhouses are built 27 ft. wide, and there are 37,800 linear ft. of these houses. In this immense flower factory, where 300 men are employed, timber at one time was used exclusively in the construction of benches, but even cypress would last only a few years, so the company began experimenting with the use of concrete. At first only the posts were made of concrete to support the wooden benches. In the greenhouses of the George Witthold Co., Chicago, benches were made 250 ft. long and 5 ft. wide, and are very satisfactory except that they cannot be moved. Poehlmann Brothers are now using benches made of concrete lumber, set up in sections.

The bench is described as follows: It consists of a 6 in. tapered post having a

10 in. base, cross beams 49 in. long, 6½ in. deep, and 1½ in. thick, resting in slots in the post; stringers 6 ft. 2½ in. long, 4 in. wide, and 2 in. thick resting on the cross beams; side pieces of "L" section, 6 ft. long by 10 in. high and 1½ in. thick, with an angle cast at the bottom 3½ in. wide forming the rest for bottom slabs. There are end pieces of the same section, and there are bench slabs 53 in. long, 9½ in. wide, and 1½ in. thick resting on the sides and also on the stringer at the centre.

The bottom slabs lock the whole structure together, so that it has all the stability of a monolith. Each member is reinforced both with chicken wire and with several ½ in. twisted square bars, except the stringers, which have two ½ in. bars only. The forms were made by greenhouse employees. All drains and sewers in these greenhouses also are of concrete.

One of the accompanying illustrations shows a bench all put together except for some of the bottom slabs, which were left out to show construction, and these pieces were set up by three men in about ten minutes, from the piles of "concrete lumber" which are seen in the background of the illustration. Other illustrations show the use of concrete block in greenhouse construction on the estate of O. C. Barber, near Barberton, O.

The Dowdeswell Gallery.

At this gallery there is a collection of small landscapes in water-colour by Mr. Oliver Hall. Like one or two other etchers who occasionally paint in water-colour, Mr. Hall seems to have acquired, in the frequent treatment of landscape in black and white, a peculiar sense of colour in nature. His small landscapes are always admirably composed, but their effect seems to depend on oppositions of dark and light (dark often much predominating) rather than on colour.

USE OF CONCRETE IN GREENHOUSES.

SOCIETY OF ARCHITECTS.

The sixth ordinary meeting of the session 1911-12 of the Society of Architects was held at 28, Bedford Square, W.C., on April 11th, at 8 p.m. Mr. Percy B. Tubbs, F.R.I.B.A., vice-president, having taken the chair, in the unavoidable absence of the President, twenty nominations for membership and six for studentship were announced.

The ballot was then taken, and the following candidates were declared to be duly elected as members:—Browne, F. A., Chelmsford; Foley, T., Yorks; Valentin, G. S., London, W.C. Ten candidates were elected as students.

Mr. C. McArthur Butler, F.C.I.S., Secretary of the Society, then opened a discussion on "Some Principles of Professional Practice and a Code of Ethics." Extracts from his paper were given in our issue of April 17th. A summary of the discussion appears in another part of the present issue.

The Annual Dinner.

The twenty-eighth annual dinner of the Society was held on Friday last, April 26th, at the Holborn Restaurant, the president, Mr. George E. Bond, J.P., being in the chair.

At the conclusion of the dinner Sir G. Lawrence Gomme proposed the toast of "The Houses of Parliament," to which the Right Hon. Lord Saye and Sele and Mr. L. A. Atherley Jones, K.C., M.P., replied.

Judge Rentoul, I.L.D., proposing the toast of "The Society of Architects," said he had always had a great interest in the Society since it came into existence in the same year as he became a barrister. On behalf of the Society he then presented Mr. Bond with a medal which, he said, he knew would be prized, not for its intrinsic value, but as the expression of the Society's strong approbation in electing him as president so many times in succession.

Mr. George E. Bond, in reply, referred to the steady increase in the Society's membership and to the progressive development of its financial position. Having recapitulated the progress of the Registration movement, and having referred at some length to the negotiations between the Society and the Royal Institute, the speaker said: "Most of you know how, after being approved by the Councils and members of both bodies, a legal hitch occurred in regard to the power of the Institute to enter into an agreement, how its Council immediately set to work upon an amendment to the Charter, with a view to surmounting that difficulty, and how it was a second time submitted for approval, in a meeting at which about a seventh of the Institutes' members were present, and which was obviously packed by an organised opposition, consisting of junior members; it was referred back, ostensibly upon a side issue about which we care nothing; and by what was practically an adverse vote, the twelve months' ceaseless thought and study given to the subject in all its bearings by their duly appointed representatives and nominal leaders has been rendered of no avail. No great progressive movement was ever carried to a successful issue without some sacrifice; but the grand ideal of our leaders, who aimed at nothing less than the establishment of that professional unity within one strong institution, which would have rendered all ethical and educational reforms within our ranks much easier of attainment; and would, at the same time, have

positively secured that unity of action in regard to Registration which is essential to success; was apparently, by some of our younger men in the profession, not considered worth even the sacrifice of a little petty pride; for with the arrogance which usually accompanies immature thought, they had no difficulty in assuming that they were perfectly justified in committing themselves to a wrecking policy before they had even heard the other side of the question. And I am convinced that all thoughtful members of the profession were both sorry and surprised to find that many members of the very class which had everything to gain and nothing to lose under any scheme of Registration, had so readily allowed their vanity to be exploited, by two or three irresponsible individuals, whose egoism constituted their one and only claim to leadership in the matter. The present position is an eminently unsatisfactory one, for I say, without hesitation, the real voice of the Royal Institute has not yet been heard upon the question."

Mr. Bond then heartily thanked Judge Rentoul, his colleagues and Council for the kindly thought which prompted the presentation of the medal for whatever services he had been able to render the Society.

Mr. Percy B. Tubbs proposed the final toast, "The Guests," which was responded to by Mr. J. S. Gibson and Mr. A. Needham Wilson, both of whom reasserted their confidence in the ultimate fusion of the two institutions.

SOCIETIES AND INSTITUTIONS.

Liverpool Architectural Society.

The annual meeting of the members of the Liverpool Architectural Society was held last week, Mr. Arnold Thornely, the retiring president, in the chair. The council recorded with regret the death of Mr. H. Blomfield Bare, who had been a member of the society for many years, and was a vice-president in 1888. The council had communicated with several of the bodies interested in the memorial to Sir Alfred Jones, the work of which had been placed in the hands of Sir George Frampton, R.A., urging the desirability of selecting a suitable site before the completion of the design, and advocating the laying-out of the landing-stage approaches in a manner which would afford many excellent sites for monumental statuary. The following officers were elected:—President, G. Hastwell Grayson; vice-presidents, E. P. Hinde and W. Glen Dobie; hon. secretaries, Gilbert Fraser and E. L. Bower; hon. auditors, John Woolfall and T. F. Shephard. As unofficial members of the council there were elected:—J. Dod, T. E. Eccles, C. H. Reilly, P. C. Thicknesse, Arnold Thornely, W. E. Willink, and R. B. Holt (fellows), and L. P. Abercrombie and F. E. G. Badger (associates).

Leeds and Yorkshire Architectural Society.

At the last meeting of this society the officers for the next session were elected as follows:—President, Mr. A. E. Kirk; vice-presidents, Mr. G. F. Bowman, and Mr. J. F. Walsh; members of council; Messrs. W. J. Morely, C. B. Howdill, G. W. Smithson, J. C. Procter, G. J. Combs, and Douglas Bowman (associate member); hon. treasurer, Mr. R. Fielding Farrar; hon. librarian, Mr. W. Peel Schofield; hon. secretary, Mr. Wm. Whitehead. A

vote of thanks was accorded to Mr. Sydney D. Kitson on his retirement from the president's chair. He had worked hard during his term of office, and with a spirit of comradeship that had been pleasant for everybody.

Devon and Exeter Architectural Society.

The "Journal of Proceedings, 1911-12" of this society contains the annual report for 1911, which gives the membership at the end of that year as standing at 82. The presidential address by Mr. James Jerman, F.R.I.B.A.; the same gentleman's "Reflections on the International Congress of Architects at Rome, 1911"; "Venice and its Reception of the International Congress of Architects, 1911," by Mr. Harbottle Reed, F.R.I.B.A.; and a summary of a paper by Mr. J. Archibald Lucas, F.S.I., on "Some Bits of Architecture from the Valley of the Loire." Lists of officers and members are included, and for frontispiece there is a portrait of the 1912 President, Mr. E. Coath Adams, M.S.A.

London Master Builders' Association.

A council meeting of the London Master Builders' Association was held in the Council Chamber, Koh-i-Noor House, Kingsway, W.C., on April 18th, the President (Mr. James S. Holliday) in the chair.

The President reported that the Special Committee and the Law and Parliamentary Committee had met, and would in due course submit their reports to the council.

Correspondence relating to Priced Schedules with Tenders, Provisional Sums in Quantities, etc., was read, and instructions were given.

Various other trade matters of interest were considered.

Messrs. Messers, Ltd., were elected an Associate Member of the Association, and the following firms were nominated for membership: (1) Messrs. H. J. Carter, Ltd., as ordinary member; (2) Messrs. Bovis, Ltd., as ordinary member; (3) Mr. J. B. Smith, as associate member.

COMPETITIONS.

Council School, Knavesmire.

The assessors in this competition Messrs. T. Mellard Reade and Son, announce the awards in this competition as follows: 1, Mr. John T. Proffitt, Walkden; 2, Mr. E. R. Barrow, F.R.I.B.A., London; 3, Mr. J. A. O. Allan, Aberdeen.

Football Grand Stand, Cardiff.

In this competition, in which Cardiff Rugby Football Club invited designs for a new grand stand, etc., the following awards are announced; 1, (£30), Mr. Leitch, Liverpool; 2 (£20), Messrs. R. and S. Williams, Cardiff; 3 (£10), Messrs. Ivor Jones and Percy Thomas, Cardiff.

OCTOBER 1. KING EDWARD MONUMENT, OTTAWA.—Designs for a monument to King Edward VII., to be erected at Ottawa, and to cost about \$35,000, are invited by the Public Works Department of that city. Sketch models in plaster (scale $1\frac{1}{2}$ in. to the foot) are to be delivered to Mr. Eric Brown, Director, National Art Gallery, Ottawa. Particulars from Secretary, Public Works Department, Ottawa.

ARCHITECT. ■ PLASTERWORK PANEL BY GEORGE JACK.

HOUSE AT GARBOLDISHAM, NORFOLK : GARDEN FRONT. P. MORLEY, HORDER, F.R.I.B.A., ARCHITECT

This house was built behind an old malthouse, on the road, and a picturesque group of buildings has been thus achieved. As will be seen from the plan on page 486, there is a small court formed by the house and former malthouse, connected on one side by a covered walkway, and on the other by a long pergola shutting off the private flower garden. The old malthouse formed useful stable buildings on one side, with a small cottage entered off the covered walkway made through the old building. The new house is of brick, rough-cast, with old pantile roof. Mr. P. Morley, Horder, F.R.I.B.A., of London, W., was the architect.

Architecture at the Royal Academy.

THE first thing that strikes one in the architectural collection at the Royal Academy this year is the large and unusual proportion of drawings of church architecture. These form such an important element in the show that they may be considered separately, on another occasion, under the heading of Church Archi-

ture. For the present we will confine our attention to the works of Academicians, and to those exhibits which illustrate public architecture.

Taking the Academicians in their alphabetical order, we come first on four works by Mr. Belcher. The "New Premises for the Royal Society of Medicine, Henrietta Street" (1,545: no plan), is a very plain building of Classic style, with a Roman Doric Order of four columns in the centre portion, and a cornice from which the orthodox frieze is omitted, and the architrave (except over the columns), decorated with a key-pattern ornament which to some extent makes it play the part of a frieze. The design is well balanced, and makes an agreeable whole, somewhat spoiled by the ornament on each side of the side windows, where a vertically depending fillet runs through six projecting blocks, as if they were pierced for it; one of the prevalent tricks of architectural ornament of this decade. Morden House, Blackheath (1,593: no plan), is merely a picture of a rather commonplace house and gardens. The interior of "Holy Trinity Church, Kingsway" (1,603), is shown in a slightly executed water-colour sketch; an interior with a semicircular plastered barrel ceiling into which the arches of the windows at the side cut in a manner that makes a very ungraceful contorted line. A band of coloured decoration on the ceiling connects the heads of these two windows, and does something to carry off their rather accidental appearance; the effect of the coloured decoration in the semi-dome over the apse is well indicated. There is no plan to this either, which is less important in a mere sketch of the interior effect of a single compartment, but the house (No. 1,593) absolutely needed a plan to give it any architectural value. No. 1,758 (no plan) is a dry mechanical elevation of Whiteley's premises in Queen's Road, all columns and glass, with an octagon cupola at each end. We should at least have had a section through the front wall to show the construction.

Professor Blomfield adds to his perspective view of "Wretham Hall, Norfolk" (1,581), a complete plan of a symmetrical mansion like the letter I laid horizontally, the drawing-room and library, dining-room and billiard-room, occupying the cross blocks at each end; the entrance being in the centre of the recessed face. It is mainly a brick house with portions of the wall emphasised by rather narrow brick pilasters, the roof line at each end being broken by a square-lined erection above the cornice, treated rather more decoratively than the rest. It is not a building to excite enthusiasm, but as house architecture it is eminently sensible; the only detail we do not quite like is the curved-out line of architrave moulding to the entrance-door, which rather quarrels with the severe lines of the general design. "Manoir de la Trinité, Jersey" (1,634: no plan), is a remark-

ably effective exhibit strongly shaded in black and white which attracts one mainly as an original and a powerful drawing; the treatment is very simple, but the projecting mouldings to form a base to the pilasters on the upper part of the porch hang rather awkwardly on to the angle. "Lincoln Free Library: details" (1,755) is a kind of drawing we wish there were more of in the architectural room; it is a working section of the entrance pavilion and dome, with details of the construction and materials completely given; a small perspective sketch of the whole building being included to show how the dome comes into the general design. That is what we call really an architectural drawing in the true sense of the word. We presume that the hanging strings and knots of flowers at each side of the doorway is a kind of detail in which many architects at present find pleasure, else we should not see it so often now; but it is a taste we cannot pretend to understand.

After this we come into the region of pictorial sketches. "A wood-frame house in British Guiana" (1,598: no plan), by Sir E. George and Mr. Yeates, is an interesting experiment in the treatment of a house of this kind in an architectural manner quite different from that of the ordinary type of wood-frame house, so as to suit it to climate and surroundings.

By the same architects is "Woodside, Esher," a water-colour drawing of a house in more of a Georgian style, with a square projection on columns forming a porch in front, and a large semicircular columned porch round the angle, looking rather too large for the scale of the house. A plan would have shown the meaning of this. Mr. Ernest Newton's "Oldcastle, Dallington" (1,623), is a very pleasing water-colour sketch of the end of a house, and No. 1,628, a small drawing showing the garden front of the same house, a long low building giving the idea of being an old farmhouse remodelled. No. 1,629 is a water colour of the garden front of "The Greenway, Cheltenham," a three-gabled house, shown nearly in elevation. None of these last-named five drawings has any plan.

Mr. Jackson does not exhibit this year. Sir Aston Webb shows carefully finished water-colours by Mr. Gascoyne of two interiors from his design. "New Chapel, Worksop College" (1,663), is an interior with a pointed-arch barrel vault in timber and plaster, the principals and rafters slightly decorated in colour; the principals spring from stone wall-shafts. The woodwork of the stalls is solid and plain in treatment, capped by a cove cornice, and broken here and there by a projecting canopy over the seat—altogether a good example of the orthodox form of College Chapel. "Offices of the Grand Trunk Railway of Canada" (1,711) shows the interior of an imposing room, the official portion forming an apse with the counter on the chord of it; the floor is boldly treated in a large simple design of black and white marble, and the wall above the wainscot pointed as a large pictorial frieze in colour. Plans are not so necessary to these two drawings, as they represent each the interior effect of a single apartment; still, plans had better have been given, if only to set a good example.

Among designs for public buildings are several for the Art Gallery at Manchester. Messrs. Adams and Holden's (1,554: no plan) is an extremely, almost defiantly solid design with masses of rustication at the angles, a colonnade along one side, and an immense blocking mass extending

over a great part of the area of the building. The elevation of the columnar front is shown in No. 1,721; the design was hardly worth two large drawings in the limited space of the Academy Rooms; its massiveness is overdone. Messrs. Warwick and Hall's design (1,557; no plan) is a better one, more refined in detail and less heavy in general effect; but we cannot understand the beauty or significance of that manner of finishing above the cornice with a mass of masonry designed so as to give the idea of two or three sarcophagi piled one upon another. Of course it meets us everywhere in competition drawings at present, but it is a mere fashion, with no architectural meaning. Mr. Worthington exhibits another design for the same building (1,568: no plan), a good Classic design with a projecting centre; in the wings the treatment with windows below and niches with statues in a blank wall above suggests the idea of its internal arrangement as a picture-gallery. Mr. Robert Atkinson exhibits yet another design (1,724: no plan), a large and fine perspective, dignified but not very original. None of these designs shows anything but the outer aspect of an Art Gallery; what the exterior is built on and how the gallery is arranged, there is nothing to show.

Mr. Cooper wisely gives two complete plans accompanying his illustration of the design for Marylebone Town Hall (1,559); it is a well-planned building, with the sole defect that the corridor communication is not continuous. When corridors on the opposite sides of a plan each end in a door to a central room, that room must become occasionally a passage, and it is better to avoid such a result. The tall tower behind the front does not seem at all necessary to the design, and there is no adequate base for it in the plan.

Messrs. Lanchester and Rickards's "Study for the Royal Memorial, Parliament Square" (1,569) is a mere sketch, but a very brilliant one, quite worth exhibiting; it shows a triumphal arch with a quadriga on the top and an equestrian statue beneath the arch; there is an extended base in the shape of steps, balustrades, and parterres decoratively arranged; the whole a fine scheme for a monument of this kind.

Professor Pite seems to be rather under the influence of Egyptian ideas in his "Design for Insurance Offices, Holborn" (1,710: no plan), for the centre feature has certainly a resemblance to a tall Egyptian square-headed doorway with the usual cove cornice over it; apparently the centre of this is filled up by three storeys of sculptured figures with openings between them. On each side of the centre are six columns of a freely treated Ionic order. All this is very good, but the details of the actual doorway seem to fit in rather awkwardly, and do not belong to the main design, nor does the square erection above the centre. It is a clever effort at something new and original, but rather wanting coherence.

In Nos. 1,722 and 1,730 we have two remarkable drawings by Mr. J. J. Burnet of the staircase in the new part of the British Museum, treated in isometrical perspective, with the main construction shown in section; a method of illustrating architectural design more in use with the French than with us. Two small plans are given as a key to the drawings, but it is not quite easy to connect them with the position of some of the columns as shown in the perspective. However, these are two of the most brilliant drawings in the room, and (like Professor Blomfield's dome detail, before referred to) represent a kind of drawing that we wish we saw more of in the architectural room.

Messrs. Smith and Brewer exhibit a large and fine perspective view of their design for the National Museum of Wales, accompanied by two plans to a fairly large scale. The design is dignified Classic, with a low leaded dome over the centre of the front block; but why not have made it an exterior stone dome? It would have looked far more monumental. The attempt to treat a dome as an exterior stone erection should be made oftener than it is; it requires care, but it has been done, and therefore can be done again. We do not quite understand how the authors proposed to work the "reserve space" all round outside the main plan. The "Clock-tower in Course of Erection at Buenos Aires"

(1,746), by Mr. Ambrose Poynter, is shown in a very large elevation drawing; it has a brick stalk rising from a two storeyed stone base of Elizabethan character, and with stone lantern above the clock face. We cannot feel very enthusiastic about the details or the general design, which is somewhat commonplace. Mr. Arnold Mitchell's "Northwestern Polytechnic" (1,749), shown in plan and elevation is an exceedingly simple brick building, with unbroke rows of windows, with a long modillion cornice; there is no much in it, but there is nothing to object to. We find three competitive designs for Marylebone Town Hall, by Messrs. E. T. and E. S. Hall (1,751), Mr. Robert Atkinson (1,750) and Mr. C. Gascoyne; all of some merit as exteriors.

A large bird's-eye view of the neighbourhood around St. James's Park, called "Design for a Development Scheme," by Messrs. Berrington and Jemmett, is of some interest though some of it does not express their intentions very clearly. They seem to contemplate, among other things, a rebuilding of Buckingham Palace, with two concave wings something like old Buckingham House, facing the new avenue up to Piccadilly. The meaning of the whole picture would have been very much helped by a small plan of the scheme, to scale; there is plenty of room for it on the drawing.

In the interior view of "The Council Chamber, New London County Hall" (1,727), by Mr. Ralph Knott, we see a very satisfactory promise as to the interior architecture of the new County Hall. The drawing, by Mr. Horsnell, which is slightly executed but in a masterly style, shows the room arranged for seating in semicircular lines, with an architectural treatment which is simple and dignified, with seated statues in the niches in the wall, which form the principal decorative incidents. There is, however, one point for criticism. It is not easy to see, from the shading of the drawing, whether the central portion of the ceiling is intended to be domical or whether it is a flat unbroken space (a small section appended to the drawing would have made this clear), but in either case that ceiling would produce echo. A ceiling, whether flat or domed, of which the surface is not broken up in any way, will always produce echo in a room of any height. That point should be considered before it is too late.

There are two models exhibited in the architectural room. One of them is a model of one façade of the Glamorgan County Hall design by Messrs. Harris and Moodie. It shows a colonnade standing free in front of the walls, stopped by two square pavilions which seem to want something on the top to finish them. The lower porches at the end do not join very well to the main block, and consequently look too much like afterthoughts. The other model is a "Sketch model of a country house," by Mr. Jaggard. This shows a good and interesting arrangement of plan around a courtyard, but a compass should have been added to show the aspect of the rooms. The model makes a picturesque whole, though the treatment of the upper storey with over-sailing construction in black and white is an anachronism in these days.

The Welsh Museum.

WE publish on page 469 a photograph of a large model of the Welsh National Museum to be built at Cardiff, which is now exhibited, by permission of the First Commissioner of Works, in the Petitions Room, off Westminster Hall. The cost of the building is to be defrayed from various sources, including local rates and voluntary subscriptions, and the Welsh Party hope to get the good offices of the Chancellor of the Exchequer to secure a grant from the Treasury. Cardiff crowned its ambition to be the metropolis of Wales by getting possession of Cathays Park, in the centre of the city, in which the Law Courts and City Hall, designed by Messrs. Lanchester and Rickards, now stand. The South Wales College of the University of Wales (designed by Mr. Caröe) is also in process of completion, and here, too, is to be erected the Welsh National Museum, the architects of which are Messrs. Smith and Brewer.

Royal Academy Pictures.

THE impression left by a general survey of the pictures this year is that it is a collection of a great many highly finished pictures, many of them very pleasing, but nothing great among them. There is no work that can be regarded as essentially the leading picture of the year, in an artistic sense, though no doubt Mr. Bacon's picture of the Coronation will take that place in a popular sense; but the interest in that kind of picture is not primarily artistic, and we would much rather have seen Mr. Bacon's talents employed on something different.

The exhibition is strongest in portraits, of which there are many fine examples, notably the two by Mr. Orpen, in Galleries II. and III.; in the former he has managed to make the head of the sitter stand out with great power in a generally light picture, without any forcing of the effect. The other work, "A Lady and Gentleman," is in the manner that he almost originated, of treating a portrait as a figure in an interior, in which the surroundings are pictorially as important as the figure; this is the best of the type that he has exhibited. Mr. Orpen seems to have fairly found himself now, and it is to be hoped he will give up experimenting. Among portraits of the more usual type, those which make no pretence to be anything but a portrait, Mr. J. Shannon's are the finest in an artistic sense, from the rich and harmonious colouring which he produces in the treatment of the costume; that of Mrs. Wigan in Gallery III. is especially fine. In this respect Mr. Dicksee's portrait of a lady in bright green, in the same room, looks somewhat crude by

trivial in subject for its size; one wants some better reason for so large a canvas. Mr. Bundy has made a spirited attempt to realise the place and the audience at "The first performance of the 'Merry Wives of Windsor'"; to give an idea of the kind of rabble of an audience for which Shakespeare's comedies were produced; it is clever and worth study, but somewhat confused in composition. Mr. Waterhouse's "Penelope and the Suitors" is a very pretty picture, both in design and colour, but anything more absolutely out of the atmosphere of archaic Greece one could not imagine; and Penelope is a young girl, whereas she must have been a middle-aged woman; it was her wealth that the "suitors" courted.

Among figure-pictures, or those in which figures are an important element, which may be counted among the successes of the year, are Mr. Henry's "The Picnic," a masterly sketch of a forest scene, in Gallery I.; and in the same room Mr. Hacker's "Imprisoned Spring," a cottage girl, the sole inmate of a room with the bright sun pouring in through the window; a little bit of pathos of real life very completely worked out in every detail. "Springtime" is a good *pointilliste* landscape with figures by Mr. Mark Senior. Then there is Mr. Stanhope Forbes's "The Drinking-trough," in Gallery III., one of those works in which a common incident of country life is translated into a picture, because the artist knows how to see it; there is nothing in the scene, one would have thought; it is the painting that does it. Mr. La Thangue's "A Sussex Common," with a boy leading a cow in the foreground, is another fine work

MODEL OF WELSH NATIONAL MUSEUM TO BE ERECTED IN CATHAYS PARK, CARDIFF.
SMITH AND BREWER, F.F.R.I.B.A., ARCHITECTS.

comparison; it is a furniture and costume portrait. The portraits of men give no opportunity for rich colour schemes; in them we have to look rather to the expression of character. In this respect Mr. Cope's portrait of Mr. S. Roberts, in Gallery V., a quiet, unassuming work which many would no doubt pass over, is one of the cleverest and most successful of its type.

Among what may be called figure subjects the late Mr. Abbey's "Education of Isabella the Catholic" (unfinished) is interesting as an obvious attempt to contrast bright English nature with religious asceticism; it would hardly have been one of Abbey's great works, but it has a point of meaning dramatically expressed. Sir L. Alma Tadema has moved from his accustomed position in Gallery III. to a place in Gallery I., with a larger picture than usual, with a less subject than usual—"Preparations: in the Museum." It is mainly a study of architectural and decorative detail in what might be called the Imperial box in the foreground, with the marble stalls for the favoured few, the mosaic-paved corridor in front of them, and the numbered seats for the populace rising in tiers behind. It is a splendid study in archaeological realism, and in perspective and texture of marble and other materials; the figure of the female attendant in the foreground is the least interesting part. Other figure subjects the largest and most ambitious are the best. Mr. Gow's "Tumult in the House of Commons, March 2nd, 1862," justifies its scale only in the subject, and in the treatment, which is unreal and theatrical; on the other hand, Mrs. Laura Knight's "The Flower," in Gallery I., a most brilliant and forcible piece of painting, is far too

of the same class. Mr. Wetherbee, in "Butterflies," idealises rural life a little, with a lovely result, both in colour and in the expressive line of the three figures in chase after the butterflies; a little less of fact here and a little more of poetry. Mr. M. Hornel, in "Crossing the Brook," is beginning to get a little more out of his peculiar programme than he used to; the figures do not look so much imbedded in a mosaic. He has been "skied" this year; perhaps a hint that he has carried on one experiment long enough.

There are some fine landscapes. Mr. Lamorna Birch, in his view in the "Wengen Heights" ("Wengern"?), has not quite equalled his "Cornwall" of last year. Sir Alfred East, in his "Tranquil River," is a little too tranquil in style; "Under the Wold," in Gallery VIII., is in his stronger manner. Mr. H. W. B. Davis has his usual number of landscapes, which are always charming, but never powerful; Mr. Arnesly Brown strikes a much stronger note in his "Norfolk Landscape." Among landscapes by less well-known painters Mr. Goodman's "The Walls of England," though heavy and loaded in tone, deserves recognition; and there is a great truth of colour and effect on the small landscape by Mr. Alfred Oliver, called "A Breezy Day."

This is certainly not a great year for sculpture; there are too many memorial statues in costume, though Mr. Drury has made something sculptural of the simple dress of Mrs. Fry the Quakeress. In the Octagon, Mr. Garbe's "The Magdalenes" is a beautiful and expressive group of two figures, though it rather needs an explanation of its intention; and in the Octagon is also a good "Fountain of the Valkyrs," by Mr. Gilbert Bayes; a piece of decorative

work on a small scale. To the same class of work belongs one of the best things in the Lecture-Room, Mr. Reynolds-Stephens's statuette of a lady, with a decoratively treated pedestal. Mr. Colton's "The River unto the Sea" and Mr. Babb's "Love and the Vestal" are both works which answer the true aim of sculpture, the indication of an abstract idea through sculptured form. There are some good small works, but the sculpture collection begins to remind us a little too much of the rows of busts of the old Academy exhibitions. That is not entirely the fault of the sculptors. There is talent enough among English sculptors, if it got more opportunity and encouragement.

The Protection of Ancient Monuments.

NO fewer than five Bills relating to the preservation of ancient monuments are now before Parliament.

They respectively bear the names of Lord Southwark, Earl Beauchamp, Lord Eversley, Mr. Russell Rea, and Mr. Noel Buxton. Lord Southwark's Bill would "extend the Ancient Monuments Protection Acts, 1882 to 1900"; Earl Beauchamp's would "consolidate and amend the law relating to ancient monuments"; and Lord Eversley's aim is "to amend the Ancient Monuments Protection Acts, 1882 to 1900, and further to protect ancient monuments." These Bills are now before us, but the others apparently are not yet printed. Lord Southwark's Bill provides for the constitution of an Ancient Monuments Board, to consist of not more than twelve and not less than five persons to be appointed by the Commissioners of Works. The membership is to include the inspector of monuments under the Act of 1882; one member each to be nominated by the trustees of the British Museum, the Society of Antiquaries, the Royal Institute of British Architects, the Ecclesiastical Commissioners, the National Trust for Places of Historic Interest; and a member of the county council or corporation in whose jurisdiction the monument under consideration is situated. The duty of the Board will be to advise the Commissioners of Works with reference to any question arising under the proposed Act. Every owner of a monument, when he proposes to sell, destroy, alter structurally, or add to or part with possession of a monument, must give the Commissioners of Works at least two months' previous notice of his intention, and obtain their consent in writing. The Commissioners of Works

may assume guardianship of a monument that is liable through neglect to become ruinous; or, if they see occasion, may have power to acquire the ownership, in which case the price may be settled either by agreement or by arbitration under the Lands Clauses Acts. The two other Bills that have been mentioned are similar in principle, but show greater elaboration of detail. In Earl Beauchamp's Bill provision is made for public access to monuments, and for punishing persons who deface them; and any county council may acquire guardianship of an ancient monument or may, at the request of the owner, undertake or contribute towards its maintenance. Lord Eversley's Bill proposes an Ancient Monuments Advisory Board, which shall exercise such functions as the Commissioners of Works may direct. The essential principle of the Bill is that it would render the owner of an ancient monument liable to penalties for injury or defacement, and would make compulsory the permissive force of the Ancient Monuments Acts of 1881-1900. "It is thought that prehistoric monuments or ruined abbeys or castles ought to be preserved and that the right of property in them should not include the right to destroy, remove, or injure them." Earl Beauchamp's Bill is of course a Government measure.

Architectural Drawing.

THE paper read by Mr. Townsend on the drawing which are in the Institute Library was a valuable summary of its contents in this department, accentuated by the numerous illustrations thrown on the screen and we are glad to find it printed in the R.I.B.A. journal; but we cannot at all agree with the President in his remark at the close of the discussion, that the younger students of the day, if they examined these drawings, would have to admit "that present-day draughtsmanship does not compare at all favourably with that of the men of former generations." On the contrary, with the exception of one or two remarkable drawings, such as Goldicutt's section of St. Peter's, we were rather struck with the poor style of many of the old drawings exhibited. Architectural draughtsmanship, whatever it may be worth in itself, has seldom been better than it is at the present moment; and we should surmise that there were men in the room on that occasion who could produce better architectural drawings than most of those exhibited as illustrations to Mr. Townsend's paper.

The altar rail and the balusters are of oak; the panels, and the balls on which the pedestals rest, being of ebony. Coromandel is introduced as an inlay.

FIRE PREVENTION NOTES.

Having for years past stood almost alone in London's "Luck." constant insistence on the necessity for educating the public with reference to fire-prevention methods, we are the more gratified to find that this point has not been overlooked in a paper by Mr. Lawrence H. Fryer which was awarded a prize in the Insurance Institute of London competitions. "There are," he observes, "many old buildings in London, and the city is to a degree congested. Its comparative good luck in the past is not an adequate guide to the future. San Francisco's record was excellent. For twenty-five years before the conflagration in 1906, the loss ratio was well under 30 per cent. Bearing this in mind, and remembering that any day may see a disaster at home, should aid us to see that every opportunity is used to educate the public respecting the advantage of building their structures to resist fire, and to advance by all means the use of fire-retarding materials." Nowadays the public accept fires in very much the same spirit of hopeless fatalism in which, in pre-hygienic days, they accepted epidemics of disease, which were accepted as an inexplicable visitation, measures of prevention being regarded as futile if not presumptuous. In the matter of fire-prevention we have hardly advanced beyond the ignorance that merges in superstition. The keen advocate of fire-prevention methods is too often met with the objections (1) that fires are sure to occur in spite of all that can be done; (2) that it is useless to build and equip on fire-prevention lines in the midst of buildings in which these precautions are disregarded; and (3) that the average architect does not know enough about fire-preventing construction to do more than increase the cost of a building without materially improving its fire-resistance.

The Apathy of Architects. With regard to (1) it is certainly true that fires, like disease, will probably continue to occur as long as the sun gives forth light and heat; at the same time it is as possible to minimise the probability and extent of fire as it is to reduce the incidence of disease and the mortality from it, and, in the one case as in the other, it is a plain duty to take all possible steps towards securing comparative immunity from danger and death. (2) To say that one is absolved from doing his duty because of the defection of his neighbours is to argue in a vicious circle; and the prevalence of this excuse is strongly suggestive of the need for all-round compulsion, which would very effectually dispose of (3) the reluctance of the average architect to acquaint himself with the ways and means of doing what is required for safety. The apathy of the average architect is but the reflex of the indifference of the general public, who, so far as educational effort is concerned, are left almost completely without guidance or stimulus; for although fire-drill in schools is now almost universal, that, after all, is an approach from the wrong side, and rather tends to foster the inveterate notion that all that need be known about fire is not how to prevent it, but how to get away from it. Unfortunately, however, the lesson that prevention is better than cure is one that is always exceedingly difficult of enforcement.

Inadequate Publicity.

One reason why architects and the general public are so ill-informed as to the means of fire-prevention is to be found in the ineptitude of many of the vendors of fire-prevention goods, who, with inexplicable modesty, refrain from taking due advantage of the ordinary channels of publicity. It is absurd that these tradesmen should so often require to be tracked to their lairs; yet it frequently happens that we are asked by architects and others to supply the names and addresses of the manufacturers or vendors of fire-prevention specialities which deserve to be much better known. We are always glad to be of service by supplying any desired information of a technical character, yet cannot shut our eyes to the fact that due advertisement would, and ought to, save our correspondents and ourselves thus much of gratuitous labour. It is very clear, however, that most people will not go to the trouble of making such enquiries. To avoid it, as well as the consequent delay, they abandon any attempt to hunt out the particular object that suggests itself as being most suitable for the work in hand, and prefer to adopt something similar which the vendors have had the good sense to keep in evidence by means of advertisement. The moral is of general application, but applies with special force to the materials of fire-prevention, which, on the whole, suffer very severely for want of adequate publicity.

Fires at Country Mansions.

During April there was almost an epidemic of fires in mansions. On April 5th, Lake House, about seven miles from Salisbury, was completely destroyed, to the great regret of all who are aware that in this way another Elizabethan interior has disappeared. The walls, which are of flint and stone, are left standing, but the interior, with its fine old roof-beams, paneling, and chimney-pieces, is beyond redemption. As usual, the outbreak has been attributed to the firing of a beam in a flue, but, for aught that has as yet appeared, this may be an unwarrantable inference. A day earlier, a fire occurred at Gibbstown Castle, Co. Meath. The damage was estimated at £40,000; the motor-engines which extinguished the fire coming from Dublin, a distance of thirty-six miles, in little more than an hour. The castle was built in 1870, at a cost of £200,000. On April 5th damage amounting to many thousands of pounds was done to Rosslu House, the seat of Sir Ian Colquhoun of Luss, at Loch Lomond. The north wing, in the drawing-room of which the fire is believed to have originated, was completely destroyed. The building was erected about 1774.

A Month's Disasters.

Thus, in the short space of three days important mansions in England, Ireland, and Scotland suffered severely from fire. This, unfortunately, does not end the tale of the month's disasters. On April 11th, considerable damage was done to Inglewood House, Kintbury, near Hungerford, by a fire that broke out in the cellars; and on April 25th there was a fire at Clumber House, the residence of the Duke of Newcastle. The damage, which was confined to the west wing of the building, was estimated at £8,000. During the month there were also several serious fires at workshop and other business premises.

A great fire at Ipswich involved the destruction of a furniture establishment, a bicycle factory, a leather-merchants' and an hotel, the damage being estimated at £100,000. A shipyard fire occurred at Middlesbrough, with damage estimated as exceeding £20,000; and five lives were lost in fires which broke out at minor premises in London.

Wanted, a Commission on Fire Prevention.

These calamities enforce the moral which must be insisted upon even to weariness—that is that something should be done to awaken the national consciousness from its strange lethargy with regard to fire prevention, and to the protection of life and property from fire. During last week an interim report reminded us of the existence of a Departmental Committee on Tuberculosis. Setting aside as unnecessary any attempt to assess the relative importance of disease prevention and fire prevention, we yet feel justified in claiming that the many deaths and other disastrous consequences resulting from fires—the huge money loss being perhaps outweighed by the irretrievable loss of venerable buildings and of their sometimes priceless artistic or historical treasures—and the appalling possibility of a calamity in London comparable in magnitude to that which reduced Chicago to ashes, warrant the demand for a Parliamentary Commission to enquire into all the circumstances of fire prevention, fire extinction, escape from fire, and the organisation of fire-fighting forces. The report of such a commission, we feel sure, would be little short of sensational in its revelations.

BUILDING CONSTRUCTION AND FIRE HAZARD.*

If we start with the axiom that "anything will burn, given the necessary conditions," we shall not be guilty of the error, so often perpetrated, of calling any building "fireproof." There is no such thing as a "fireproof" building, so we will content ourselves with calling the best "fire-retarding."

Conflagrations are best avoided in the manner of construction of new buildings and the improvement of the old. A great deal may be done in reducing the fire hazard in buildings by regulating their construction under suitable by-laws, but far more important is a constant supervision of building work and of the framing of by-laws relating to it by those interested in the prevention of fire.

It is often difficult to induce the occupant of a building to take the necessary precautions to prevent setting fire to his neighbours' property by efficient separation or protection of openings, yet, if he would reflect for a moment, he would see that the same protection holds good for his own building from the risk of fire from his neighbour's property, and whereas he is only one, his neighbours are many, and his own risk of exposure much greater. In existing buildings which cannot be called fire-retarding, the risk of fire spreading is greater than in new buildings, and so far as possible they should be constantly improved. Timber in or near chimneys and hearths should be removed or protected with cement, and particular care be taken that the walls of chimneys are not rendered less secure. It has

*Extracts from a prize paper by Mr. Lawrence H. Fryer in the Insurance Institute of London Competitions, 1911.

occurred, in making a cupboard in proximity to a flue, that the enclosing wall has been made thinner to add to the space in the cupboard, a wooden lining being put in, and this attached to wooden stops in the flue wall. Where stops are required in walls, particularly in party walls, to which joists or other woodwork are nailed, they should be made of fireclay. These blocks are capable of receiving and holding nails quite as effectively as wood. Trimmer arches in hearths should be inspected in repairing a building, and wooden floor joists not allowed to approach within a reasonable distance of the fireplace. Wood linings and partitions, where necessary, should be treated with some fireproofing material, preferably some cyanide solution. This is obtainable in all coloured paints, and as wood stain, and is undoubtedly retardant to the combustion of wood and textile fabrics. One of its most valuable uses is for the stage fittings of a theatre. The London County Council require scenery to be treated with some such solution to conform with their by-laws.

Linings in boiler-houses, in storerooms, in corn mills, and in any compartment in a manufactory where heat is generated, should be made of fire-resisting materials, such as uralite, asbestos, or other mineral composition. Similar materials should be used for drying rooms in laundries, breweries, maltings, sawmills, hat factories, tanneries, and others where goods in various stages of manufacture or process have to be dried or conditioned. Both boiler-houses and drying rooms should be isolated from the remainder of the premises by protecting all openings with fire-resisting doors. Concealed spaces should be avoided as far as possible, so that a fire may not spread unseen. If they exist in floors, they can be remedied by filling in with pugging, consisting of cement, silicated cotton, and hair. If they are made in floors or walls for pipes, ducts, or conveyors of any kind, the holes should be of no greater size than to admit the pipes, etc., and should fit close round them. In the case of conveyors or ducts, these should be made of metal, and have a metal shutter on each side of the opening in floor or wall. Holes for shafting should have a metal shield fitting close round the shaft. Hoists and lifts should be cut off from the main building by fire-resisting doors, and the enclosing walls of the lift or hoist should be increased in height above the roof of the main building.

The external hazard consists of the exposure to fire of one building from another, or of one storey from another, by means of openings in walls and roofs. This feature of risk is perhaps greatest in those cases where the buildings are for warehouse purposes. Such buildings are usually large, and require much daylight; and three or four warehouses enclose a hole into which windows look from all sides. In London, where building regulations are more strict than in provincial towns, the warehouses are mostly brick or stone, but many streets are so narrow, compared with the height of the buildings. In Manchester and Glasgow the areas allotted to warehouses are generally wider streets, but the buildings themselves are of inferior quality, and timber entering into their construction. Skylights and other roof lights are frequent causes of the spread of fire. The spread of the Cripplegate conflagration is attributed mainly to these.

Iron and metal-covered shutters, wire mesh, electro-copper glazing, wired glass,

and drenchers are the chief methods of protecting external openings; of these electro-copper glazing should be placed first, with wired glass as a cheaper substitute, of almost equal merit. They will not easily break under heat; the glass may crack, but will not fall away; the metal will not corrode nor rust under natural influences or fumes, and concussion will not seriously damage them. If metal shutters be used, they should conform to the specification of the fire offices, and the work of making and fixing them be entrusted to competent firms. The same stipulation applies to wired glass and electro-copper glazing. Particular care should be taken that they are fixed in metal frames, and that no solder is used.

For the protection of internal openings Messrs. Mather and Platt construct armoured doors of both folding and sliding types, which are fitted with an ingenious apparatus for closing automatically. In the case of sliding doors they are hung on an inclined rail, and when open are held back by a weight on a rope running over a pulley. In the rope is a piece of fusible metal, which melts at a certain temperature and releases the weight. The door then slides into place by gravity. It should be possible to find some mechanical means by which all window and door openings could be closed by one action from a point outside the building on the ground floor.

In turning to the subject of new buildings reference must be made to one point in the London Building Acts. In the London County Council by-laws, made in conformity with these Acts, the following materials are given for use in staircases—viz., "York or other stone, or fire-resisting materials, to be approved by the Council." Why should stone be particularly mentioned, especially in conjunction with "fire-resisting materials"? Stone when heated to a high temperature and submitted to the influence of water will crack and fly about, and be rendered very unstable. In fact, a strong oak or teak staircase will not burn through at the same temperature as will render stone unsafe, and the application of water to wood when at a high temperature will not cause it to disintegrate like stone. The difference in the behaviour of brick, terracotta, concrete, and cement when submitted to fire and water is so wide that it would appear expedient to make some distinction in their use. Brickwork and concrete might be classified as almost equally efficient both for walls and for covering metal work. Cement alone is not so reliable in resisting heat. Plaster is weaker still, for it will very soon disintegrate under the combined influences of fire and water. Terra-cotta is a faulty material for covering structural ironwork, owing to the difference in the ratio of expansion between the two materials.

In putting up a fire-resisting building, the chief considerations are—(1) resistance to heat and to combined influence of heat and water; (2) compressive and tensile strength in resisting abnormal strain; (3) water-tightness; (4) conductivity; (5) resistance to deterioration from natural influences and wear and tear. The first consideration is obvious. By the combined influence of heat and water is meant the liability of a substance to expand and contract under quick changes of temperature. The second consideration is important in view of the risk of materials of great weight falling during the progress of a fire. Water-tightness must be considered in some buildings with a view of preventing loss to goods which may be affected by water. Conductivity, though

seldom given sufficient thought, is very important in warehouses, dry goods stores, etc., where large stocks of inflammable goods may be piled up against walls, through which sufficient heat to set them alight may be conducted from a fire on the other side, while the fire may not be sufficient to penetrate.

Deterioration of a building material may weaken it so much as to allow a fire to work from point to point where it was least expected. In the earlier forms of fire-resisting construction—viz., unprotected metal and masonry—none of these requirements can be said to have been complied with. Indeed, the behaviour of unprotected or insufficiently protected metal work, when subjected to the influences of fire and water, has been demonstrated, and the lesson reiterated so often that it seems superfluous again to mention it.

The developments in the use of metal and concrete have not been rapid, but now that so much more is known of the qualities of concrete, its manufacture has become a science in itself, and the better standard attained in it makes the scope of its uses far wider, irrespective of the fact that it is one of the finest fire resisters known. Of Roman structures, e.g. the Pantheon in Rome was built of lime concrete 2,000 years ago, and Portland cement concrete is admitted to be superior to lime concrete. Reading Abbey had a concrete core and stone facing. The stone has crumbled away with age, but the concrete remains. The water-tightness of concrete may well be illustrated by the following occurrence, in spite of statements that with age concrete loses this quality. A fire occurred in a reinforced-concrete cotton spinning mill at Fives Lilles in 1907 (the mill had been built eleven years before). The fire was confined to the upper storey in which it broke out, and the damage done was to the goods and machinery on that floor, which were destroyed. The water-tightness of the floor prevented damage to goods and machinery in the lower floors, and the mill, with the exception of the floor on which the fire broke out, was working three days after. The hardness and impenetrability of concrete will prevent rats and mice and other vermin from making holes and runs in a building constructed of it. These holes are known causes of the spread of fire.

The kind and size of the aggregate used in mixing concrete is important. If it consists of large stones, its stability is threatened in case of fire by these stones cracking and disintegrating the concrete. Cinder as the aggregate in concrete is not satisfactory. Its resistance to fire is very small, so much so that it has been known to catch fire. The Prussian Government have prohibited the use of coal residues in concrete or reinforced-concrete floors. The lessons to be learnt from the San Francisco fire, the biggest conflagration on record, are numerous. Many buildings there had cinder concrete in their construction, and the results were most unsatisfactory. Captain Sewel, U.S. Corps of Engineers, spoke in strong terms of the deficiencies of this form of concrete, and in one case the floors of the building constructed of cinder concrete supported by unprotected iron columns were practically ruined, although the heat was not sufficient to affect the bare ironwork.

The difference in expansion of terracotta and iron is said to be the cause of the failure of so many buildings in Baltimore. Many buildings were constructed on the principle of metal frames protected by terra-cotta, and its behaviour was similar to that in San Francisco.

The floors of the Civil Service Stores in Haymarket were built on Messrs. Dennett and Ingle's principle in 1881, and they appear to have acted very well in the two fires which occurred there, one soon after their construction and another in 1903. In each case the fire was confined to the floor on which it broke out, and in the latter case the heat generated in the packing room, where the fire originated, was intense, owing to the inflammable nature of the goods that were stored there. These were quite destroyed.

Reinforced-concrete construction, from the comparatively few recorded instances of its behaviour in fire, can apparently claim to possess the requisite qualities of a first-rate fire-resisting material.

With the march of civilisation in the mechanical appliances for saving labour and time, in the manifold uses of electricity, in the height of buildings, their size, number of occupants, etc., we are constantly increasing the opportunities for the outbreak of fire. But against this we have the increase in knowledge of fire resistance and scientific research, and we can best apply this knowledge in endeavouring to confine a fire to its origin, in preventing its spread from room to room and from building to building, and so securing the greatest degree of safety for inmates. The construction of a building on sound fire-retarding principles is the key to this, and proper supervision during the process will attain the best results.

IN PARLIAMENT.

(By our Press Gallery Representative.)

Victoria Tower Garden.

In the House of Commons, Captain Murray asked Mr. Wedgwood Benn, representing the First Commissioner of Works, whether he could give an approximate date for the completion of the garden which was to be laid out on the site now being cleared in Millbank Street; whether plans had yet been prepared showing the dimensions of the garden and the manner in which it was to be laid out; and whether he had any other information to give to the House in the matter.

Mr. Benn, in reply, said the plan for laying out the Victoria Tower Garden, as enlarged, was now under consideration. The First Commissioner could not say when the work would be finished, but it was not likely to be before the summer of next year. He proposed to put the plans, when they were completed, in the Tea Room for the inspection and approval of members. It had been suggested to him that he should provide a site in the garden for the group of statuary by Rodin known as the Burghers of Calais.

In reply to Captain Jessel, Mr. Benn stated that it was the intention of the First Commissioner to lay down wood-paving instead of macadam in the portions of Abingdon Street and St. Margaret Street which were under his control.

Museum of Safety Appliances.

Mr. McKenna has informed Mr. Wardle that the Government have decided to establish a museum of safety appliances, and the arrangements are now in hand. The selection of the site has taken a little time, but the offer of a suitable site in a central position in Westminster has now been accepted, and provision has been made in the estimates for commencing the erection of the building in the course of the present year.

Sub-Inspectors of Quarries.

In reply to Mr. H. Jones, who asked

whether the examinations for sub-inspectors of quarries would be conducted by a gentleman having a practical knowledge of slate quarrying, Mr. McKenna said the examinations were conducted by the Civil Service Commissioners, but he was informed by them that the technical portion of the examination was in the hands of well-qualified experts.

King Edward Memorial.

Mr. Asquith, answering Colonel Yate, said an opportunity would be given the House of recording its opinion on the proposed memorial to King Edward VII. in the Green Park on the vote for the Office of Works, which would be taken at an early date.

Rates upon Land Value.

A Bill which has been brought in by Mr. Neilson, and read a first time, enables local authorities to relieve ratepayers from paying rates in respect of buildings and fixed plant and improvements, and to adopt land value as the standard of rating. The Bill has very little chance of again being heard of this session.

Peter Pan.

In the House of Commons, Mr. France asked Mr. Benn, as representing the First Commissioner of Works, in view of the fact that consent had been given for the erection of a statue to Peter Pan in Kensington Gardens, if he was prepared to accept offers from other authors, from actor managers, or from business firms for the erection of statues to commemorate and to increase the fame of persons or wares in which they and the public were deeply interested. Mr. Benn replied that the First Commissioner had already promised not to authorise the erection of any more statues in the Royal Parks without consulting Parliament.

Office of Works Architectural Assistants.

Mr. Snowden inquired whether any decision had been arrived at in regard to placing the class known as architectural assistants engaged in the Office of Works upon the established list whether the undertaking given on the 7th December last that the wishes of all the men in this class in regard to their desire to be established would be ascertained, had been carried out; and if any scheme had been prepared, whether he would state the nature of the proposals made.

Mr. Benn said the scheme had been submitted to the Lords Commissioners of his Majesty's Treasury, which provided for the establishment of a staff of permanent architectural draughtsmen and technical assistants the architects.

Protection of Ancient Monuments.

Three of the Ancient Monuments Protection Bills, now before Parliament—namely, those introduced by Earl Beauchamp (First Commissioner of Works), Lord Southwark, and Lord Eversley—have been read a second time and referred to a joint committee of both Houses. This committee will probably hear evidence after Whitsuntide. Bills dealing with the same question have also been introduced in the House of Commons by Mr. Russell Rea and Mr. Noel Buxton.

New Imperial Institute Building.

Mr. Radford asked Mr. Benn whether a new building was being erected on a portion of the site occupied by the University of London and the Imperial Institute, known as the North-East Quadrangle; and if so, for what purpose the building was to be used, and would it be open to the public. Mr. Benn replied that the building was being erected by and at the cost of the Imperial Institute in one of the quadrangles which had not been appropriated to either body

exclusively. With regard to the last two questions he referred Mr. Radford to the Colonial Secretary.

Cork Post Office.

Mr. Augustine Roche asked the Postmaster-General if he would explain the cause of the delay in proceeding with the enlargement of the post office buildings in the city of Cork, having regard to the fact that the plans of the proposed improvements were lodged with the city engineer in 1911; and whether he could now state when the works would be commenced.

Mr. H. Samuel stated that it had been necessary to reconsider the original proposals for improving the accommodation at the Cork Post Office. A revised scheme which did not involve the purchase of additional property had now been authorised, and provision had been made for commencing the work during the current financial year.

A Trade Protest.

In reply to a question by Mr. Tyson Wilson, Mr. Churchill stated that a portion of a glazed partition in No. 15 Storehouse was taken down and re-erected by skilled labourers in order to change the position of the doorway. The work of the removal and re-erection, using the same fittings and glass, was considered such as might be reasonably be performed by the skilled labourers who were employed on it.

Town Planning in London.

Sir Arthur Griffith-Boscawen asked the President of the Local Government Board whether he could state what steps had been taken under Part II. of the Housing and Town Planning Act, 1909, by any of the local authorities of London and of what was termed greater London; and whether, in view of the tendency of the population to move outwards and the desirability of encouraging this tendency, and in view also of the great multiplicity of authorities in greater London, he would consider the possibility of forming a housing and town-planning board to embrace the county of London and the districts outside with a view to attaining uniformity and consistency in the planning of these new districts.

Mr. John Burns, in a printed reply stated: The London County Council are the only local authority in the administrative county of London under Part II. of the Housing and Town Planning Act, 1909, but I am not aware that any steps have been taken by the council with a view to the preparation of any town-planning schemes.

As regards districts in the immediate vicinity of London, Ruislip-Northwood and Hanwell have received authority to prepare schemes, Walthamstow has made application for such authority, and Enfield, Southgate, Finchley, East Barnet, Hendon, Willesden, Wembley, Bushey, Greenford, Hayes, Southall-Norwood, Acton, Twickenham, Barnes, Richmond, Ham, Esher and the Dittons, Surbiton, Maldens and Coombe, Merton, Epsom, Epsom Rural, Sutton, Carshalton, Croydon, Croydon Rural, and Beckenham have all taken some steps in the matter and many of these authorities have been in consultation and co-operation with one another. On the information before me, I should not be disposed to regard the formation of a housing and town-planning board for greater London as desirable but I should agree that in certain matters there should be consultation and co-operation between the local authorities and I should expect the London County Council to take a leading part in securing it.

CORRESPONDENCE.

The Housing Problem in London.
To the Editor of the ARCHITECTS' AND BUILDERS' JOURNAL.

SIR,—In your issue of April 24th, the contributor of a note under the above heading suggests that the writer of the "Times" articles and I are both shutting our eyes to facts in suggesting that districts may be developed so as to be occupied by different classes of people; but is not your contributor drawing arguments from a degree of intermixture of houses which has not been suggested, and allowing these arguments to influence him in discouraging another degree of intermixture to which in reality his arguments do not apply?

The great evil, which every effort should be made to avoid, is the aggregation into different suburbs of a town of very large numbers of people exclusively belonging to one class, whether that class be the working, the middle, or the upper class. This I believe can be avoided by the careful planning of the district, allotting certain areas to different classes—areas which, for one reason or another, are specially suited for that class. There is already sufficient evidence up and down the country to prove that this is not only practicable, but that it is not in any way objected to by any of the classes provided for.

The arguments which your contributor suggests as bearing on the matter really only apply to an attempt to mix up indiscriminately different classes of people in such a way that their difference of habit and life, their difference in tastes, and so forth, would be constantly causing friction. This degree of intermixture, however desirable it might be from a sociological point of view, is not suggested by any of us as being at present practicable. It seems a pity to accept tamely as inevitable a segregation of classes into different suburbs which has sprung from definite causes that are being and can be removed. One of those causes is undoubtedly the squalid appearance of the ordinary lower-class suburban district, with its entire lack of amenity, due to the overcrowding of the houses on the land, and the absence of all attempt to make the streets pleasant for passers-by.

Where the cottage areas of a district are built with as much attention to general amenity of arrangement and building, and with as generous provision of open spaces as is devoted to the villa areas, it will be found that the two areas can be planned in close proximity to one another with considerable mutual advantage, and without any deterioration in the value of the larger houses. Surely, to the degree that this is possible, everybody will admit that this is desirable.

RAYMOND UNWIN.

Hampstead, N.W.
The American Frame House.
To the Editor of the ARCHITECTS' AND BUILDERS' JOURNAL.

SIR,—I was much interested in the article which appeared in your journal dated March 20th on "Cheap Cottages," and the reference therein to frame construction, and it occurred to me that a short description of the American frame house might be of interest to your readers.

In Western Canada frame construction is very largely adopted for houses and larger buildings of all kinds—banks,

churches, stores, etc. It is the cheapest and quickest form of construction, and makes a satisfactory building from all points of view.

The process of building a cheap frame house in Western Canada is as follows:—The basement is excavated for to the full extent of the house, as the furnace and piping require considerable space. The external walls up to ground floor (which is kept about 3 ft. 6 in. above ground-line) are built (around Winnipeg) of local rubble limestone, 16 in. to 18 in. thick, and on top of the wall is placed a plate 2 in. by 4 in., halved at angles, and bedded in mortar. This plate receives the joists, which are spiked to it, and the ends are carefully beam filled to keep out the cold. Then a rough floor is laid diagonally over the whole house, which is then ready for the frame walls. These are built of 2 in. by 4 in. uprights 16 in. apart, and a whole side of the house is framed-up on the ground and hoisted into position. The sections are spiked together, and the roof rafters fixed. Openings for windows and doors are cut out later.

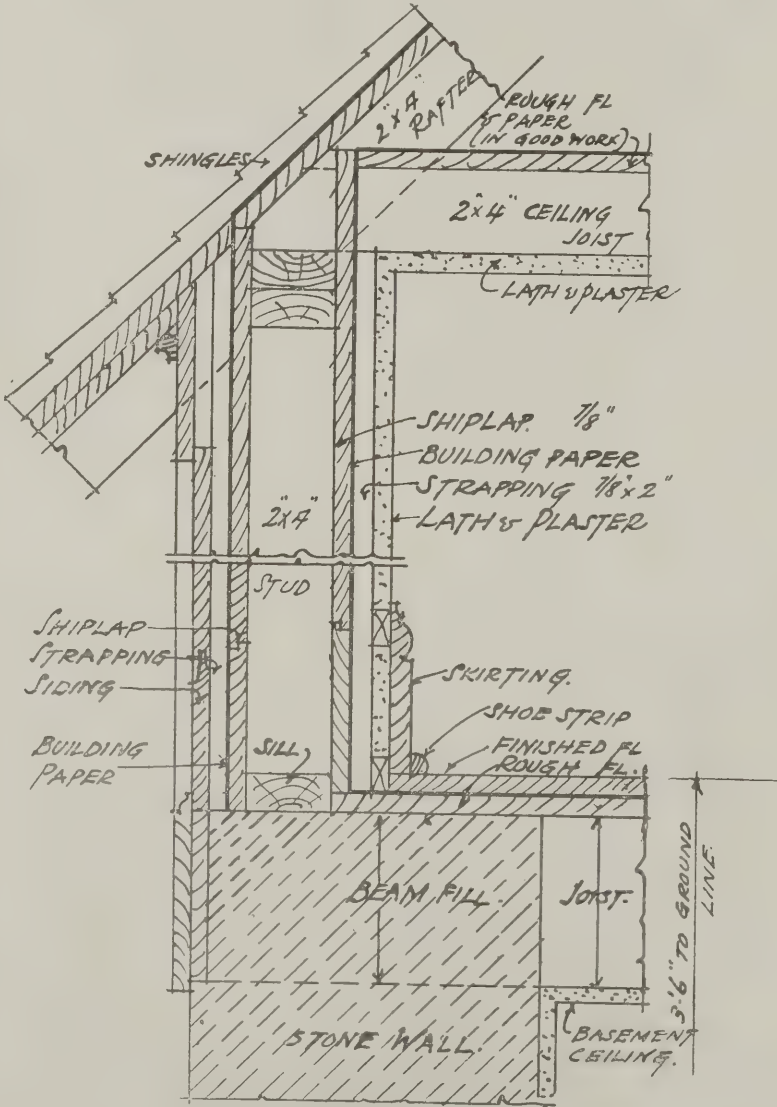

The whole of the walls and roof are then covered with $\frac{7}{8}$ in. rebated boards,

known as shiplap; the rafters are generally cut off square with the walls, to allow of a good weathertight job being made of the papering at the eaves. The walls and roof are covered with very thick tarred paper, securely lapped at the joints and held in place with $\frac{7}{8}$ in. by $1\frac{3}{4}$ in. strapping, which also receives the finishing lumber, which may be siding as shown in the diagram, or shingles.

The short rafters forming the projection of the eaves are nailed on over the paper, which thus removes the difficulty of fitting the paper around them.

The inside of the house next receives attention; a layer of shiplap is first nailed to the studding, then building paper, and finally strapping to receive the lath-and-plaster.

There is nothing about the framing of a house of this type which cannot be done by anyone able to use a hammer and saw. There is practically no framing in the building, all joints being secured with wire nails; and this is all that is necessary, for the double boarding does all the bracing required. A house of this description, with the addition of double windows and doors, is good enough to keep out the high winds prevalent in this

SECTION AT SILL & EAVES THROUGH WALL OF FRAME HOUSE.
0 3 6 9 12.
INCHES

SECTION SHOWING CONSTRUCTION OF AMERICAN FRAME HOUSE.

district, and the cold, which occasionally reaches 40° below zero Fah., or 72° of frost; and I have never seen dampness come through the walls.

In building a similar house in England, I should think the inside boarding and paper could be omitted; but the outside papering is most important, as it keeps out wind, cold, and rain, and some of the papers used are guaranteed vermin-proof.

The average life of a frame dwelling is from twenty to thirty years, although there are many buildings in Winnipeg which have stood for nearly twice that time. The cost of upkeep is more than with a brick house, as the exterior needs painting every two or three years.

The standard building lot in Winnipeg is 25 ft. by 100 ft., with a lane at the rear, and the small six-roomed house is usually built 20 ft. wide, which leaves 5 ft. between the houses. The number of fires in frame dwellings is remarkably small—electric lighting is universal—but it is easy to see that if a fire did once get a good start on a windy day whole blocks would disappear.

The point I want to emphasise is that it is possible to build a thoroughly warm and sanitary dwelling entirely of wood, and one that will be sufficient to stand even such a range of temperature as we get in Winnipeg—130° F.

ALF. B. SCARLETT, Architect.
Winnipeg, Manitoba.

The Decadence of English Architecture.

To the Editor of THE ARCHITECTS' AND BUILDERS' JOURNAL.

SIR,—When the work of designing important London buildings is entrusted to foreign architects, it is evident that there is something radically wrong with the architectural profession in England. In the cases we have in mind, it can scarcely be urged that the buildings are of such a special nature as to require the services of foreign architects, in preference to those which one might reasonably expect could be equally well rendered by our fellow-countrymen.

Why, then, have the owners of these buildings thought it advisable to go so far afield for the professional assistance they required? We are afraid the answer must be that the owners have had sufficient discrimination to see that they are likely to obtain a better result by the employment of the foreigner. In other words, it is impossible to obtain the services of English architects who have been equally well trained in the technique of their art. The dearth of highly qualified men in this country is due to our present unsystematic and inefficient mode of architectural training. And so long as we remain without properly organised and properly administered schools of architecture, we may anticipate that the work of the better trained foreign architect will be more and more in evidence in the United Kingdom.

Recognising this fact, it is imperative that the architectural profession should seriously consider what steps can be taken to cope with the difficulty.

It seems to us that following the formulation of a sound and comprehensive scheme of architectural education, the Government should be approached to give its financial support to enable the scheme thus put forward to be realised in its entirety.

We are aware that the British Government rarely, if ever, does anything

in the cause of art; but in this particular case it might be induced to see what foreign countries have long ago realised—namely, the undoubted fact that good architecture is a national asset, and, as such, State assistance to art education has proved a sound financial investment.

But, however good such a scheme may be in theory, and however well endowed, all would go for nothing unless the direction of the students' work were under the absolute control of specially trained men. Handicapped as they have been in the past by the non-existence of any school for the advanced study of their art, the architects of this country cannot be expected to furnish the necessary teachers.

It would seem, therefore, that upon its inauguration a National School of Fine Art would have to rely upon obtaining professors from foreign countries. To those who do not know the details of the system of architectural training which has been carried on so long and successfully in France, the following brief description of the curriculum of study at the Beaux-Arts may be of interest.

After a competitive entrance examination for admission, the student in architecture attends a course of lectures on each of the following subjects:—Mathematics, Descriptive Geometry, Stereotomy, Physics, Chemistry and Geology, Construction, Perspective, Building Regulations, History and Theory of Architecture.

In addition to the foregoing subjects which are specially applicable to the training of architects, it has been wisely felt that as architecture is but one branch of art, it is necessary that its exponents should receive at least some instruction in the sister arts of painting and sculpture.

As the architectural student receives specialised instruction, so in like manner do the painters and sculptors become specialists in their separate arts. But prior to this specialised training, all students of the Ecole des Beaux-Arts, whether painters, sculptors, or architects, are obliged to attend a course of study on Design, Modelling, Elementary Architecture, Literature, and Decorative Design.

By adopting this method of training, painters, sculptors, and architects are taught at an early age to appreciate the merits and necessary limitations of their colleagues' work. The exponents of the three arts thus become accustomed to work together, and it is only by this appropriate application of their united efforts that a homogeneous and thoroughly satisfactory artistic result can be obtained.

To compare the results obtained under this methodical training with those that follow the haphazard system (or want of system) in vogue in this country is not only humiliating and depressing, but shows that our much-vaunted commercial instinct in this instance is disastrously astray.

This is only one aspect of the many problems relative to the welfare of the architectural profession which show the urgent necessity of obtaining statutory powers to enforce a satisfactory system of architectural education.

So long as we are content to see untrained men allowed to practise in this country, just so long will the decadent period of architecture now existent be apparent.

GEORGE HUBBARD,
A. W. S. CROSS.

Shop-Front Architecture.

To the Editor of THE ARCHITECTS' AND BUILDERS' JOURNAL.

SIR,—The article appearing in your issue of April 17th, headed "Regent Street Architecture," overlooks the obvious fact that the man who pays the piper usually calls the tune. There are no "imaginary notions" about the style of shop-front that pays a shopkeeper. It is certain that huge stone piers are absolutely detrimental from a business point of view. The writer of your article is very severe upon shopkeepers as a whole, classing them as vandals and holding up his ideals of "noble and dignified street architecture" as represented by the shop-fronts in the Piccadilly Hotel. He would rout the whole tribe of ignoramuses from their prosperous plate-glass shops, and bundle them neck and crop into a row of railway arches. They must be taught better; they must be taught that their customers come out on fine days to study the street architecture not to go shopping, and that the shopkeeper who can show the nicest display of architectural features and stone wall will do the most business.

London shopkeepers always have controlled London street architectural features and they always will, for the simple reason that they have to find the money to pay for them. The shopkeepers of London have made the streets the gold mines they are to the ground landlords and property-owners, and these gentlemen will always study their own financial interests when erecting shop premises.

Rent-day is the pivot of the question, not a noble vista.

The article argues for a return to mediæval styles in shop windows, and instances a tobacconist's shop with an old-style front. This business is probably one that would do as good trade with no window at all—there are many such in the West End of London—and to drag it into the argument is an irrelevancy. Probably not two per cent. of a tobacconist's customers ever look into the window. When milady goes a-shopping she does not view the shop from afar off; she does not even stand in the centre of the road and take stock of the building; she just goes along with her eyes glued to the plate glass, and is more interested in picking out the particular shade of ribbon she is in search of than in rhapsodising over the architectural treatment of the premises. She votes the stone piers of the railway arch type of shop a plaguy nuisance.

The many weary years some of the Piccadilly Hotel shops stood tenantless proves conclusively that the elevation is unsuitable from a business-bringing point of view. Rental value is not a matter of opinion—it is a matter of fact—hard solid fact. There is a shop, not at all a large place, on offer in Regent Street at the present moment for £6,000 per year rent. At a rough guess this is at the rate of £200 a foot frontage. It would be rather serious to have to pay rent for stone piers, in this proportion, to please æsthetic tastes of folks who do not have to earn the money, and, provided they occasionally get a good eye-full, care little if the shopkeeper (or vandal) gets a living or not.

The shop window is a showcase, and always will be a showcase, because its mission is to get the money. A stone wall is always a stone wall, and wastes valuable frontage. Architectural superiority sounds good, but shopkeepers want

daylight and space, and every inch of the street they can get.

We acknowledge the debt the world owes to Mr. Norman Shaw for the impressiveness and grandeur of his conception, and we are with the writer of the article in wishing for an improvement in the styles of London business premises. But to the latter gentleman we would say that shopkeepers are a very wary lot, and have learned by experience that plate-glass—and plenty of it—draws business. And that the intolerant attitude in the article will not go far to teach them the error of their ways.

E. POLLARD AND CO.

29, Clerkenwell, Road, E.C.

ENQUIRIES ANSWERED.

Town Planning Parties.

IONA writes:—"I wish to make a study of town planning, and should be glad of your advice. During the month of June or July I intend spending a month abroad. Please advise as to suitable countries to visit. Do you know of any parties that I might join?"

—Parties to study town planning are being arranged by the National Housing and Town Planning Council (address Mr. H. R. Aldridge, 18, Dulverton Road, Leicester); also possibly by the Garden City and Town Planning Association (address Mr. E. G. Culpin, 3, Gray's Inn Place, W.C.). The most instructive countries to visit are France and Germany. In France, such towns as Paris and Nancy, for example, should be visited, and in Germany town planning is practised in nearly all the towns.

As to books, read Camillo Sitte in French or German; Stübben in German and in English; also the "Proceedings of the Town Planning Conference," October 1910, obtainable from the R.I.B.A.; "Town Planning in Practice," by Raymond Unwin; "Town Planning," by Inigo Triggs; "The Town Planning Review," issued by the Liverpool University Press, quarterly. R. U.

Sand-faced Rough-Cast.

C. K. T. H. writes:—"There is, I believe, a kind of rough-cast known as 'sand-faced,' being of a less rough texture than the ordinary variety. Kindly give the specification for this."

—Fine rough-cast is executed in a precisely similar manner to the coarser varieties, the pebble-dash being of finer gauge. Specifications of rough-cast have been several times given in this column. Texture is sometimes given to the rendering in Portland cement and sand (1 to 3) by dabbing the floated surface with a wood float covered with coarse sacking or old carpet, or scratching it with a drag. This method gives a better effect, when limestempered, than any more even method. G.

Water on Site.

F. H. H. writes:—"During the erection of a cinematograph theatre, water appears on the site, which causes extra cost in excavating, strengthening the foundations, and pumping; and it is also found necessary to have a layer of asphalt laid on the floor. We may mention that in the agreement there is nothing provided for an emergency such as this, and our contract is to erect the building as based on the plans and specifications. Are the proprietors responsible for the extra cost entailed by the unexpected appearance of the water

(which is probably caused by a spring or small springs underneath), or is the contractor liable?"

—The information given is insufficient to enable a definite opinion to be expressed. When the water was encountered, the question of liability for the cost of the remedial measures should have been settled before proceeding with the work. It would then have been necessary to prove by the original contract whether the builder was responsible or not, and in the latter case an order for extras should have been required from the proprietors or their architect. If the builder proceeded to remedy the water without taking these precautions, he would appear to have assumed a responsibility from which only a sense of fairness on the part of the proprietor can relieve him. A. G. W.

Band-stand Design: Question of Acoustics.

A CORRESPONDENT writes:—"What constructional points should receive attention in the designing of a band-stand, in order that the acoustics may be satisfactory? The site chosen is an open one, on a mound of earth some 10 or 12 ft. above an esplanade and gardens, where the listeners will principally assemble, although there will probably be a walk around the band-stand on top of the mound for the accommodation of some of the audience."

—The band-stand should be built entirely of wood, with wooden supports for the roof. The floor should be boarded, with some space underneath, which need not be enclosed; better not, in fact; a boarded floor with space under it makes a resonator. The roof should not be in a dome-like form; that catches and retains some of the sound. It should be more like the accompanying sketch; the form

of roof shown keeps the sound down and drives it outwards. For getting rid of the rain from the roof, there would be two methods: either have a false outer roof on the top, as dotted, discharging into a gutter around the sides; or the roof may be left in its cup-like form, leaded on the upper surface, the rain being taken away by a central vertical rain spout (dotted on section), discharging into the gutter beneath the band-stand. The first way would have the better external appearance; the second is the more simple, though the central rain-pipe might be a little in the way, and perhaps the centre position may be thought the best for the conductor of the band. The false roof may therefore be the best, though a little more costly. H. H. S.

Concrete Slab Beneath Floor.

H. T. W. G. writes:—"I wish to build a small two-storey house on a hard sandy foundation. It is my intention to put down a concrete slab 6 in. thick over the site; in other words, to extend the concrete beneath the boarded floors under the footing as well. Please say whether the concrete, having no load, is likely to fracture under the middle of a floor."

—No gain in strength will result from the continuation of the surface concrete beneath floors to form the wall foundations, unless adequately designed reinforcement is added; and even then 6 in. will be thin. Consider the two possible eventualities. If the soil is compressible or likely to shift, the weight of walls transmitted to the outer edge of the slab will throw a cross strain on the concrete as soon as settlement begins, owing to the absence of load beneath the floors, and this strain will result in fracture. If the soil is incompressible, so that there is no tendency to settlement under concentrated loads, the concrete—slab or otherwise—serves no real purpose. G.

Exudation from Pine.

ABIES DOUGLASSII writes:—"I have been using Oregon pine treated with three coats of Carbolineum for the internal joinery of a house, but find that an exudation takes place, apparently of resin, especially where the sun gets upon it. Kindly inform me if the wood can be treated in any way to prevent this."

—I have heard of no other case where Oregon pine has shown serious exudation where used in joinery. Is it certain that either pitch pine or sugar pine was not substituted? Their appearance is not dissimilar. The former is, of course, well known to ferment if coated in any way likely to prevent free evaporation of turpentine, and the latter contains reservoirs of saccharine matter which is likely to produce such an effect as described. It is an American wood scarcely known in this country. I know of no treatment likely to stop the trouble permanently. G.

Reversible Fireplace.

A. O. C. writes:—"I have an indistinct recollection of a patent fireplace which was somehow arranged so that it could be turned round and used in the adjoining room, thus being available in two rooms. I cannot find any advertisement of this fireplace; perhaps you may be able to supply the name of the makers."

—Some time ago a Royal personage, visiting a new block dwelling, expressed the opinion that it would be highly convenient if the living room and parlour fireplaces were so arranged that the fire could be transferred from one apartment to the other when desired. This incident obtained wide publicity in the Press at the time, and we are under the impression that in a later block the experiment was tried, but whether the contrivance is on the market we cannot say. Perhaps the maker will respond to this.

Penalty Clause in Contract.

SUBSCRIBER writes:—"A contract was made under the following conditions: Building to be completed within six weeks, or penalty of £5 to be inflicted for every day exceeding the stipulated time. In making the necessary excavations, water and fibrous matter was encountered, making it necessary to go

considerably below the footings originally shown on the plan. This work was charged as an extra and accepted by the proprietor as such. Would this cause the contract to be broken? Two weeks' bad weather was experienced, and the excavations involved $8\frac{1}{2}$ weeks over contract time. There was no signed stamped agreement."

—The exchange of a tender and an acceptance constitutes a contract; the fact that it has not been stamped, however, may involve the party who sues under it in trouble with the Inland Revenue. The fact that the proprietors accepted an extra charge for extra work to foundations probably vitiates the penalty wholly or in part, but it will be a question of fact depending on the circumstances whether and how far this was so.

A. G. W.

Action of Frost on Mortar.

R. I. (Mussoorie) writes:—"Kindly give your opinion on the action of frost

on lime mortar. Is it mechanical or chemical, or a combination of both? I ask this question as I find that lime mortar, after it has been exposed to the action of frost, becomes absolutely inert, and resembles a mixture of sand and ashes. This would not be the case if the action of frost were only mechanical."

—The true inwardness of the setting of mortar has never yet been satisfactorily explained. It is often assumed that intermolecular penetration takes place between the particles of lime and the sand or other aggregate to which it adheres, forming a silicate-of-lime cement between them, but this, so far as I am aware, has not been proved. In this state of knowledge it is difficult to define the precise action of frost on lime mortar. What is certain is that frost swelling the moisture in the mortar arrests the process of crystallisation, and causes internal disruption of the mass, and that the setting process thus arrested is not resumed—an explanation which appears to depend on mechanical action.

G.

Effect of Heat on Mortar.

W. W. (London) writes:—"What is the effect of great heat on bricks laid in (1) lime mortar, and (2) cement mortar?"

—The effect of great heat on lime mortar and on cement depends entirely on the duration of exposure and the temperature. Momentary exposure to the most intense heat will only effect a partial fusion of the material, which will tend to increase rather than diminish strength as a binder. If, however, the exposure is prolonged, even at a relatively low temperature, the tendency will be to dehydrate the lime or cement, destroying the bonding power and reducing the cement or mortar to a more or less loose friable mass.

It is extremely difficult to ascertain precisely the effect of a fire on brickwork for the exterior of the mortar may appear to be quite sound on account of a superficial partial fusion, whilst the interior has been robbed of its binding power through the action of radiated heat. On the other hand, the exterior may appear to have been destroyed, whilst the interior is still as sound as ever, and pointing is all that is needed. Under such circumstances it is cheapest in the end to consult an expert in mortars, and to follow the advice he gives after he has examined the site. Such a man knows from past experience the almost indescribable signs which distinguish safe from unsafe mortar, and his opinion would therefore be more reliable than that obtained from an ordinary architect or builder. We advise you to consult Dr A. B. Searle, The White Building Sheffield, on the matter, as he has paid special attention to this subject.

Tip-up Baths: Question of Rating.

A. W. writes:—"A pair of houses comprising kitchen, sitting-room, parlour and three bedrooms, are fitted, in the kitchens, with patent tip-up baths. The water supply to the houses consists of one service tap—one w.c., no water being laid on to baths. The local council demand a water rent, which, in the demand note, is under the heading of fixed baths. I have objected on the grounds that the term 'fixed baths' implies a separate and additional water tap, and also that strictly speaking the baths are not fixed. I declined to pay but, having considered my objection, the council demand payment. Can a rate in such circumstances be legally enforced?"

—I can find no recorded legal decision upon this rather interesting point.

There appears to be no logical reason for treating the "tip-up bath" (as described) as a fixed bath, and I am of opinion that, under the circumstances the local Council will find themselves unable to enforce their demand. I advise that the remainder of the water rate be tendered, but that the portion referring to "fixed baths" be repudiated. F.S.I.

A PAVILION FOR AN ITALIAN GARDEN IN ENGLAND.

The subject set in the design competition recently instituted by the Northern Architectural Association was a "Design for a Pavilion to be erected in an Italian Garden in England." The design which we now publish, by Mr Marcus K. Glass, of Newcastle, was awarded the first prize.

The only condition made was the size

PERSPECTIVE VIEW

DESIGN FOR A GARDEN PAVILION. BY MARCUS K. GLASS.

of the building, which was restricted to 50 ft. by 25 ft. An endeavour has been made to design the building and its setting, together with the lay-out of the surrounding garden, on good Classic lines.

The lower floor is divided into three compartments, the ante-rooms having separate access to the terraces and being subdivided from the central compartment by means of bronze sliding doors. Over the central compartment is a circular gallery reached by spiral staircases, the walls of the latter being carried up to the springing of the dome, which is of reinforced concrete covered externally with gilded copper slates. Over the ante-rooms are balconies or roof-gardens entered from the gallery.

PRIVATE HOUSE LIGHTING BY ELECTRICITY.*

BY W. R. RAWLINGS.

Dwelling-houses may be roughly divided into three types—namely, (1) the cottage, or artisan's dwelling; (2) the middle-class house; and (3) the mansion, both town and country.

The first type—namely, the cottage—being the humblest of the three, has, until recent years, been practically neglected as far as electric lighting is concerned, for obvious reasons, but it is now generally agreed that it offers a promising field for enterprise.

Coming next to the middle-class house, we find that, while there is, of course, much more demand for increased illumination and decorative effect, there are naturally limitations as to expenditure. Town and country mansions offer the best examples and opportunities of the highest developments of artistic illumination.

What is the proper amount of light required? In the author's opinion the art of illumination in the home is not to illuminate any room equally all over, but to produce the proper light and shade effect, according to the purpose for which it is intended.

There is no difficulty in providing a certain number of foot-candles for this or that purpose; the problem of house illumination is not so much one of foot-candles as of convenience, taste, and personal requirements.

It may be admitted that there is a minimum limit in foot-candles for specific work. For instance, a bedroom is comfortably illuminated with a variation from .2 to 1 foot-candle, but the dressing table and the part in front of the dressing mirrors must have at least 6 to 10 foot-candles on the dressing table surface; but this amount of illumination must be confined to these special positions.

A dining table requires not less than 2.5 foot-candles, and need not exceed 3.5; but the ceiling and walls of that room should be kept from .5 to 1 foot-candle, so that the surroundings may be subdued in comparison with the table, and for this reason the author did not advocate here indirect illumination.

Most people occasionally seek the shelter which is to be found in the alcove, conservatory, and the shade of the palm, and it is only when the actual illumination for specific work is required, such as for reading, writing, and the illumination of special objects, that the brighter light is desired. The billiard table perhaps provides an good example

as any of this contrast effect. It is well known that while the player likes a strong light on the table, he prefers a lower illumination for the rest of the room. It might, perhaps, have been thought that to illuminate the billiard table properly a volume of light, such as that given by a skylight, would have been desirable; but, as a matter of fact, professionals prefer the method of local illumination.

The author knew of nothing more uncomfortable than a room equally illuminated on every square foot of the floor, and a room so lighted was, in his opinion, in-artistic. He suggested the following rules for illuminating the home: (1) That a room should not be evenly illuminated all over. (2) The filament of the lamp should be so placed as not to be in the line of vision under normal conditions. (3) The position of the light should be so placed as to illuminate specific objects (according to the nature and purpose of the room.) (4) That small units of light are in general to be preferred. (5) Indirect lighting should only be used for general lighting, or as supplementary to the necessary local illumination.

The time is coming when the illuminating engineer will also be a party to the arrangement of windows and the selection of the colour scheme. At the present time this phase of the art is frequently settled without his experience being consulted at all. The engineer is set the task of illuminating the house as he finds it in the best manner possible. The problem frequently assumes the form, not "How best to illuminate the house," but "How the problem can be solved to the satisfaction of the employer and his friends," most of whom have opinions of their own; and, since they pay the piper, it is natural they should desire their ideas to be carried out.

It is a common experience to be met with the remark that "it is not fashionable now to use brackets"; or another will remark "that no one thinks of fitting pendants"; while a third insists upon having nothing but standards, each in turn raising objections to one or other of the three fixtures. It is therefore a matter of tact in obtaining more or less a compromise between what is considered correct and what the powers that be insist upon.

It is seldom that the engineer is allowed free scope in placing the lights as he in his opinion thinks best, and, in a word, it is more difficult to satisfy the taste of the owner than the actual requirements of the house.

Not only do opinions differ as to the fittings, but there is a greater diversity with the individual as to the amount of light required. Some ladies insist upon having a light of 20 to 30 foot-candles on the dressing table, while another complains that one-fourth that amount is too much, from which it will be readily seen that it is difficult in the case of private houses to specify the illumination in foot-candles even for a specific purpose.

Again, one has to take into consideration the positions of the windows and the general arrangement of the furniture. In many instances the old positions which were allocated to gas or oil, permanently fixed with a view of being within easy reach, must be retained. For the owner, having adapted himself to the general inconvenience of the arrangement, will insist upon the new lights being in the same position as the old. Many absurdities of lighting to-day

are due to this and the other causes which have been mentioned.

The town house requires more light than the country house; the same people who consider a 16 c.-p. lamp too strong in the country will complain that a 30 c.-p. lamp is insufficient when in town. This diversity is one of importance in all lighting problems, and plays most important part in the illumination of houses. Excess of light in the town compels the same fault to be perpetrated in the home, and for this reason the hall and corridors should never be illuminated to a higher degree than the rooms. The effect would be to render the remainder of the lights insufficient by contrast. The author had known a number of cases where the illumination of the house generally was considered satisfactory until a metal filament lamp had been fixed in the hall, doubling the original candle-power and causing dissatisfaction with the rest of the lighting (which until then was considered ample). It is therefore important that in no case should any excess of light be provided in the less important positions in the house, such as the corridors, etc.

The author then illustrated by a series of thirty-five slides, which he described in detail, some of the foregoing suggestions as to how the present-day house should be illuminated.

In conclusion, the author said that by stimulating discussion on these matters, the Society will make more fully understood that the nature of good illumination in the home, the advantages of various styles of lighting, and the mistakes to be avoided; and the contractor who has studied these matters will be in a much better position to put his views forward; for, having definite knowledge at his disposal, he will be able to explain to consumers *why* a certain course desired is not advisable, and he will have behind him the conclusions of the Illuminating Engineering Society in doing so. Having confidence that his contentions are correct, he will be able to advise consumers much more effectually, and to induce them more readily to accept his view. In this way we may hope to avoid many mistakes which ultimately create dissatisfaction, and of which the contractor not infrequently bears the blame. There are many points in private house lighting which remain to be discussed and settled, and the Society, by promoting mutual education in these matters, should help to raise the status of the contractor and enable him to assume a more independent position.

SOCIETIES AND INSTITUTIONS.

MANCHESTER SOCIETY OF ARCHITECTS.

Forty-eighth Annual Report.

At the annual general meeting of the members of this Society, held on April 24th, the report and accounts were approved and adopted, and the following officers and members of council were elected: President, Mr. John Brooke, F.R.I.B.A.; vice-presidents, Professor S. H. Capper, M.A., A.R.I.B.A., and Mr. F. B. Dunkerley, F.R.I.B.A.; honorary secretary, Mr. Isaac Taylor, F.R.I.B.A.; assistant hon. secretary, Mr. J. T. Halliday, A.R.I.B.A.; members of council, Messrs. A. E. Corbett, John Ely, W. C. Hardisty, Joseph Holt, P. D. Lodge, Paul Ogden, Claude Paterson, J. H. Sellers, G. Sanville, Edgar Wood, J. H. Woodhouse, and P. S. Worthington.

*Extracts from a paper presented at a meeting of the Illuminating Engineering Society, April 16th.

Supplement to THE ARCHITECTS' AND BUILDERS' JOURNAL, Wednesday, May 8th, 1912.

This drawing is one of a set now being circulated among the Allied Societies by the Board of Architectural Education as an example of the style of draughtsmanship approved under the new alternative scheme of Problems in Design which are to take the place of Testimonies of Study for the Final Examination of the Royal Institute of British Architects.

In the forty-eighth annual report, it is shown that the aggregate membership is 283—comprising 112 Fellows, 118 Associates, and 53 students—an increase of one as compared with the number recorded in the preceding report. The Council have decided to divide the whole area of their extensive province into twenty-seven districts, and to appoint in each an architect to act as correspondent for his district. By this means it is hoped to keep in touch with outlying parts, and to obtain the very earliest information of any proposed competitions and town-planning schemes, and generally to extend the usefulness and influence of the Society.

The Council successfully interested itself in the preservation of the old Town Hall in King Street, supporting the proposal of the Parks Committee to re-erect the scholarly and dignified façade to a suitable position in one of the parks, and contributing £25 towards this object. The public interest having been thus stimulated, the Parks Committee agreed to re-erect the façade in Platt Fields.

Reports of the Education, Competition, House, Library, Town Planning, and Students' Committees show healthy activity in all these directions.

Nottingham Architectural Society.

The Council of the Nottingham Architectural Society report that they have been in consultation with the building trades employers with regard to the difficult problem of specialists and sub-contractors, and have also considered the scale of charges suggested by the Royal Institute and the legal liability of architects. They have also brought pressure upon the framers of competitions to ensure fair conditions and reasonable payments. As the jubilee year of the society commences next November, the council have been asked to consider how best to celebrate it.

At the last meeting of the Society the following elections took place:—President, Mr. E. R. Sutton; vice-president, Mr. H. Gill; members of council, Messrs. R. Evans, W. R. Gleave, A. Marshall, E. H. Heazell, and H. G. Watkins; associate members, Messrs. A. Dale and H. A. Dickman; honorary secretary-treasurer, Mr. F. M. Royle; hon. secretary of the designing club, Mr. W. H. Swann; honorary librarian, Mr. R. Spencer.

Institution of Civil Engineers.

At last week's annual general meeting Mr. R. Elliott-Cooper (London) was elected president, and Messrs. A. G. Lyster, M.Eng. (Liverpool), B. H. Blyth, M.A. (Edinburgh), John Strain (Glasgow), and G. R. Jebb (Birmingham) were elected vice-presidents.

Leicester Society of Architects.

Mr. A. H. Hind, A.R.I.B.A., has been elected president of this Society for the ensuing year, with Messrs. W. A. Catlow, W. E. Keites, S. P. Pick, H. H. Thomson, C. J. M. Cowdell, and N. B. Robertson as Council.

London University Site.

Replying to Mr. McCallum Scott in the House of Commons on the question of the proposed new site for London University, the Prime Minister said he understood that a less sum than £375,000 would be accepted for the site on the Bedford estate. He was not aware that the question of the value of the site referred to had ever come before the L.C.C.

THE NEW R.I.B.A. PROBLEMS IN DESIGN.

As already announced in our columns, the alternative Scheme of Testimonies of Study for the Final Examination of the Royal Institute of British Architects will come into operation at the option of the candidates in November next, and after the end of the year 1913 the existing Testimonies of Study for this Examination will be abolished. Six alternative Problems in Design will be set by the Board of Architectural Education each year, and candidates for the Final Examination must submit designs in answer to at least four of these problems. These alternative problems will be published twice a year, three sets in January, and three in July. The subjects set for the first half of the present year were:—

Subject I.

(a) A large Monument, to commemorate King Alfred's refounding of London one thousand years ago, for a public place in the City, not to cover more than 500 superficial feet; (b) A Terrace of Five Houses, 20 ft. frontage, each six stories high, including basement, facing the parade of a small watering-place.

Subject II.

(a) A large Monument to an Explorer, to be placed against the wall of a public

building; (b) a Cloister with external entrance gateway or tower to a collegiate building round a courtyard 100 ft. square.

The drawings for subjects 1 and 2 have already been submitted by students in the United Kingdom, and two of the sets are being circulated among the Allied Societies as examples of the class of drawing that is desired. These two are by Mr. H. Chalton Bradshaw and Mr. W. Harding Thompson, students at the School of Architecture, Liverpool University. Mr. Bradshaw's design for a monument to King Alfred is reproduced as the Centre Plate in this issue. Mr. Harding Thompson's design for a terrace of houses will be reproduced in a later issue of this Journal.

Subject III.

The third subject set comprises (a) A Detached Ballroom to a large country house, to be connected with the house by a covered way; decorations to be specially considered. (Shaded drawings to $\frac{1}{2}$ in. scale showing both interior and exterior, and a detail of decorations.)

(b) A Landing Stage to a river or lake, with a restaurant. (Drawings to show complete construction $\frac{1}{8}$ in. scale and $\frac{1}{2}$ in.) The date for submission of designs in this third subject is June 30th for the United Kingdom.

BY H. CHALTON BRADSHAW.

COMPETITIONS.

Swansea Police Station Extension.

The competitive designs for the extension of the Swansea Central Police Station, with the erection, under the same roof, of a police court, are now being adjudicated. There are about half a dozen sets.

Church at Carrington.

The designs of Mr. W. Curtis Green, F.R.I.B.A., have been selected by the assessor, Mr. E. S. Prior, F.R.I.B.A., F.S.A., for the first premium in this competition. Specially commended: Mr. C. Gascoyne, Mr. Macdonald Gill, Mr. G. C. Horsley, F.R.I.B.A., and Mr. Charles Spooner, F.R.I.B.A., all of London.

Winnipeg Parliament Buildings.

In this preliminary competition, in which the Government of Manitoba invited designs for a building of the estimated cost of £400,000, Mr. Leonard Stokes, P.R.I.B.A., has selected the following five architects to take part in the final competition: Messrs. Brown and Vallance, Montreal; Messrs. Clemsha and Portnall, Regina, Saskatchewan; Messrs. E. and W. S. Maxwell, Montreal; Messrs. Sharp and Murray, Toronto; and Mr. F. W. Simon, F.R.I.B.A., Liverpool. Each of these competitors will receive a sum of 2,000 dollars. The competition was limited to architects being subjects of the British Empire, and practising therein.

Bristol Town-Planning Scheme.

At Bristol a town-planning competition is being promoted to deal on broad lines with the whole of the environments of the city where building is likely to take place. The competition is being arranged by a special joint committee of the Bristol Society of Architects, the Somerset, Gloucestershire, and South Wilts committee of the Surveyors' Institution, and the Bristol Civic League. The committee is at present engaged in drawing up the conditions of competition, which, it is hoped, will take place some time during the summer. It will not be confined to local competitors, but will be thrown open to the country generally. The conditions, which will follow those of the competition held at Halifax last year, will ensure that the plans submitted will be of such a character as to be of service to the Corporation if they think fit to make use of them when the town planning of Bristol is eventually undertaken.

Municipal Buildings, Padiham.

This competition for plans of a town hall and other municipal buildings is mainly for the purpose of laying out the ground, and Mr. Arthur S. Brewis, secretary of the Manchester Society of Architects, states that it is not the intention of the promoters to carry out much, if any, of the building scheme in the near future. As the only remuneration offered for the complete plans of all the buildings is two small premiums, the Competitions Committee of the Society have been endeavouring to induce the promoters to meet the special conditions either by some guarantee for the employment of the successful architect, or by substantially increasing the amounts of the premiums offered. The promoters, however, cannot see their way to vary the terms already offered. Mr. Brewis is instructed by the

Council to inform members that these conditions are unsatisfactory, and that they must not submit any designs in this competition.

Hale Town Planning.

Mr. Arthur S. Brewis, secretary of the Manchester Society of Architects, has informed the members that the Hale Urban District Council decline to make any alteration in the conditions of their town-planning competition. Each competitor, he says, has to purchase Ordnance sheets for the district at a cost of about 25s., and as these were last revised in 1908, he will have to go over the whole district and embody the numerous buildings since erected. The competitors are also asked to estimate the total amount of their charges should they be successful. As the duties are to a very large extent at present unknown, this becomes an almost impossible task. There is no guarantee that any qualified assessor will be appointed, either to adjudicate on the plans or to advise the Council. The Competitions Committee of the Manchester Society of Architects approached the Hale Council before the conditions were issued, and as soon as the conditions appeared they pointed out to them the unfairness of the points mentioned above. The Council of the Society consider that these conditions are unsatisfactory, and direct that members of the Society must not submit, either directly or indirectly, any designs in the above-mentioned competition.

THE AUSTRALIAN CAPITAL.

The following correspondence appeared in the "Times" last week:—

To the Editor of the "TIMES."

SIR,—The attention of the Council of the Royal Institute of British Architects has been called to a telegram in your issue of April 16th in which your Sydney Correspondent states that the designs for the Federal Capital have been reduced to a dozen, most of them the work of Americans, Frenchmen, or Germans, and the British designs have only a small chance. In the absence of fuller information this statement would naturally lead your readers to think that British architects have been unsuccessful in competition with foreigners in the planning of the new Australian city. The facts are these. When the conditions of the competition were published by the Minister of Public Works the Australian Institutes of Architects at once protested against their unfair and unsatisfactory nature. There was no proper provision made for the appointment of qualified assessors, and the Australian Institutes warned the Minister that unless the conditions were amended their members would refuse to take part in the competition. The Minister refused to adopt the suggestions of the representative architectural bodies, and they accordingly vetoed the competition. They then appealed for support to the Royal Institute of British Architects, of which they are affiliated societies. The Royal Institute, which entirely agreed with the attitude of the Australian Institutes, endeavoured both by correspondence with the Minister and by deputation to the Acting High Commissioner in London, to induce the Australian Government to put the competition on a fair and proper basis. The Minister again refused to alter the conditions in any way, and the Royal Institute supported the action of its affiliated societies in Australia by issuing

a veto to its members against the competition and by informing the American Institute of Architects, and the principal architectural bodies on the Continent, of the action which it had taken in the matter.

There is reason to believe that the great majority of the architects of the Empire have loyally supported the decision of their representative bodies and have not entered for this competition.

IAN MACALISTER, Secretary, Royal Institute of British Architects.
London, W.

The gist of the cablegram to the "Times" is that "The designs for the Federal Capital have been reduced to a dozen, most of them the work of Americans, Frenchmen, or Germans," and it was added that the British architects had but a small chance, which, taking all the circumstances in consideration, is an unfortunate and unfair observation.

To the Editor of the "TIMES."

SIR,—A letter on the above subject appeared a few days ago in your columns signed by the Secretary of the Royal Institute of British Architects. That letter has just been brought to my notice and I beg leave to reply.

It contains the very serious statement that no proper provision has been made for the appointment of properly qualified assessors. The Australian Minister assured the Australian and British architects that the assessors should be thoroughly qualified professional men, and this assurance has, I believe, been faithfully carried out by the appointment of the following gentlemen: Mr. J. M. Coane, chairman, Mr. J. H. Smith, and Mr. John Kirkpatrick. The secretary is Mr. C. J. Clarke. The chairman is a well-known consulting engineer and surveyor in Melbourne. Mr. Smith is president of the Victorian Institute of Civil Engineers, and Mr. John Kirkpatrick is a Sydney architect of great ability, who was a member of the committee appointed by a preceding Government to report upon the suggested city for the capital. The secretary appointed is Mr. C. J. Clarke, a Tasmanian architect.

The nature of the competition must be kept in view. It is not for a building, or series of buildings. It is to submit a design for a new city and surrounding on a vacant piece of country, with all the town, street, garden, and park planning such a project involves.

Commonwealth Offices, Westminster.

FEDERATION NEWS.

Conciliation Proceedings at York.

A meeting of the Local Conciliation Board was held in the Old Council Chamber of the Guildhall, York. Councillor G. Sharp, chairman of the board, presiding. With respect to the joiners' notice for increase in wages to 9d. per hour instead of 8½d., the following resolution was carried unanimously:—"That all payments be reckoned by the hour, and 8½d. per hour be the standard wage to all of fair average ability; such wage to be increased to 8¾d. per hour on January 1st, 1913." No minimum period for duration of this alteration to rule was fixed by the Board.

A question of walking time was referred to the Northern Centre Board

NEWS ITEMS.

Peter Pan in Kensington Gardens.

In Kensington Gardens on May Day Sir George Frampton's bronze figure of Peter Pan, with his fairies and mice and squirrels—the gift of Mr. J. M. Barrie—was disclosed at the tail of the Serpentine.

The Liverpool Chair of Civic Design.

At a meeting last week the Council of the University of Liverpool established a Chair of Civic Design and appointed to it Mr. S. D. Adshead. Mr. Adshead has previously held a lectureship in that subject in the University.

A Swimming Bath for Children.

A swimming bath specially designed for the teaching of swimming to school-children has been constructed by the Ealing Town Council. It is 65 ft. long, 27 ft. wide, and has a depth ranging from 3 ft. to 5 ft. 3 in.

New Embankment Garden.

The river front to the west of the Houses of Parliament is to be beautified this summer by a public garden extending from Lambeth Bridge to the Victoria Tower Gardens. The site is now being cleared.

Change of Address

Messrs. Gale, Durlacher and Emmett, architects and surveyors, have removed their offices to 15, New Bridge Street, Ludgate Circus, London, E.C. Their telephone number will in future be—6888 City.

New Buildings at Downside Abbey.

Cardinal Bourne visited Downside Abbey, near Bath, on Thursday last, to bless and open a large addition to the school buildings which has recently been erected from designs by Mr. Leonard Stokes, F.R.I.B.A.

A Work on Russian Architecture.

We have received from Mr. Nicholas Lanceroy, of St. Petersburg, prospectus of a volume entitled "Retrospective Exhibition of Architecture in Russia in the XVIIIth and first half of the XIXth Centuries." This work, edited by the Society of Russian Architects and Artists, has just been published.

Another London Hotel.

Another great London hotel is being planned. It is to be called "The Green Park," and is to occupy a site in Piccadilly overlooking the Green Park. It will cover an area now occupied by Nos. 108 to 115, Piccadilly, and Nos. 14, 16A, 18, 37, and 39, Brick Street.

"The Sprinkler Bulletin."

This quarterly publication, which is issued by Messrs. Mather and Platt, Ltd., Queen Anne's Chambers, Westminster, renders good service in the cause of fire-prevention by recording instances of the efficacy of the sprinkler system, and by showing the manner of installing them under varying conditions in different classes of buildings, of which excellent views are frequently given. The current issue contains articles on sprinklers in silos and in post offices, notes on recent great fires, a quotation from the "Insurance News" attesting that automatic extinction has been "an enormous boon both to the insured and to the fire offices," an illustrated description of an important

installation of sprinklers in the largest drapery establishment in South Wales, a quarterly fire report showing instances in which, in the United Kingdom, on the Continent, and in the Colonies, the sprinkler system has come into play, and other interesting information of similar character.

The Old Manchester Town Hall Facade.

At last week's meeting of the Manchester City Council Mr. E. F. M. Susman protested against the decision of the Parks and Cemeteries Committee to erect the facade of the old Town Hall in Platt Fields, as many residents had come to the conclusion that its erection would spoil one of the beauty spots of Rusholme. Mr. Tom Fox, deputy chairman of the committee, said they had no objection to taking the matter back for further consideration.

Transference of Practice.

Mr. J. Houghton Spencer, architect, No. 5, Hammet Street, Taunton, announces that, owing to impaired health, he has disposed of the practice carried on by him at Taunton continuously for forty-four years past to Mr. F. W. Roberts, F.R.I.B.A., architect, No. 2, Hammet Street, Taunton, who will continue to carry on the same at No. 2, Hammet Street, in conjunction with his own practice carried on by him in Taunton for the past twenty years.

A Business Appointment.

Mr. V. Zingler, for seven years manager of the Publicity Department of Messrs. Siemens Brothers and Co., Ltd., has been appointed manager of Messrs. Ozonair, Ltd., 96, Victoria Street, Westminster, London, S.W., in succession to Mr. R. Borlase Matthews, Wh.Ex., M.I.E.E., who is joining the General Electric Co., Ltd., 67, Queen Victoria Street, E.C., in order to devote his attention to the promotion of the sale of electric heating and cooking apparatus.

Reopening of Boulter's Lock.

After being closed for two months for enlargement, Boulter's Lock, Maidenhead, was reopened last week. The old lock was 152 ft. long and 18 ft. 6 in. wide; the new lock is 200 ft. long and 21 ft. wide, and it can be divided by intermediate gates, so that when the traffic is small, time may be economised by using one compartment instead of the whole. In place of the old rollers there is to be a mechanical boat conveyor, to consist of two electrically driven moving platforms crossing Ray Mill Island. It is hoped that the conveyor will be ready for service by Whitsuntide.

Alterations at the Hotel Cecil.

The alterations which have been in progress at the Hotel Cecil for some time past are now completed. The carriage approach through the Strand arch has been reduced to one-third its former size, and the floor space thus obtained, with the site of the lounge, which has also been absorbed, has been converted into two Palm Courts. The lower Court is about 93 ft. by 45 ft. and 32 ft. high, and the upper Court, which is reached by a wide flight of steps and is 4 ft. above the level of the lower Court, has a length of 110 ft., a width varying between 28 ft. and 34 ft., and a height of 28 ft. A covered way 10 ft. wide has been made between the

lower Palm Court and the east block for entrance to the hotel. The architect for the work was Mr. E. Keynes Purchase, F.R.I.B.A. All the decorations are in Louis Quatorze style.

The New Middlesex Guildhall.

The Duke of Bedford on Thursday last laid the foundation-stone of the new Middlesex Guildhall, Westminster, which is being erected on a site opposite the Abbey. Mr. James S. Gibson, F.R.I.B.A., is the architect, and Mr. James Carmichael the contractor.

Brighton Aquarium Improvement Scheme.

At the Brighton Aquarium it is proposed to construct garden terraces about an acre in extent, with level approaches from the Marine Parade, these terraces to link up with the existing Madeira Drive terraces, forming an attractive promenade to the eastern end of the cliff. A terrace for the performances of the municipal orchestra will be provided, with approaches both from the Aquarium and the Marine Parade, while a concert hall will have seating accommodation for 3,000. A winter garden, with promenade or lounge attached to the concert hall for reading, writing, and refreshments, is also suggested. The total cost of the scheme is £30,000.

Nottingham Parish Church.

Last week the foundation-stone was laid of a new chancel aisle and organ chamber for St. Mary's, the parish church of Nottingham. The building is estimated to cost about £4,000, the whole scheme, including the provision of a new organ, costing about £7,700. The new chancel aisle, which is to serve for the organ chamber and morning chapel, extends from the east wall of the south transept, along the south side of the chancel, to within one bay of the existing east end. The new chapel will open into the chancel by an arcade of three lofty arches, and the height of the chapel is to be the same, to the wall-plate, as the existing chancel. The three old south windows of the chancel are to be fixed in the south wall of the new chapel, and a new window, of similar design, will be placed at the east end of the aisle. Much of the old stone removed from the south wall of the chancel is being used in the erection of the additional aisle, the new stone being from Houghton. The roof of the aisle is of oak, covered with lead. The architect is Mr. Temple Moore, F.R.I.B.A., F.S.A.; the builder being Mr. Ullathorne, of Selby, and the clerk of works Mr. Thomas Fisher.

Public Opinion and the Prevention of Vandalism.

The Bishop of Winchester presided at a meeting held at Farnham Castle recently at which a society was formed for the preservation of the ancient features of the town and for promoting its beauty in future developments. The Dean of Wells, who is on a visit to the Bishop, said that such societies were needed all over England. Such a society would be of the greatest advantage to them at Wells. It was a city of wonderful beauty, not only in the cathedral and its buildings, but also in the city itself—the old houses, the old inns, the almshouses, and various charming features—and these were in constant peril of a very insidious kind, because it was no one's business exactly to look after them. The delay in the disappearance of one very interesting feature was partly due to the excellence

of succeeding mayors, who were unwilling to have their names associated with an act of barbarism. He thought it important that they should recognise the difficulties which beset civic authorities in many of these matters. They found themselves often very helpless as individuals, but were most ready to accept the informal help which came from the quickening of public opinion.

School Accommodation in London.

The Board of Education have notified the London County Council that they are prepared to accept the suggested scheme for the regular writing down over the next fifteen years of the accommodation of the class-rooms to 48 for infants and 40 for other children on certain conditions. The chief condition is that the proposal must be put into such a definite shape that it shall be easy for the Board to test and check from year to year the regularity with which it is being carried out, and must be stated in such clear terms that no risk shall arise of a dispute between the Board and the Council on the question whether the agreement is or is not being adhered to. Before the proposal is finally accepted an agreement must have been reached between the Board and the Council, with all the definiteness and precision possible,

on a programme, extending over not more than five years, for remedying existing defects and supplying existing deficiencies in school accommodation. When the programme is finally accepted, the Council will be immune from the Board of Education regulations which may be made during the fifteen years regarding school accommodation.

Five Losses in April.

In a statement, appearing in the "Times" of May 2nd, of the home fire losses in April, it is shown that the total estimated losses amounted to £332,650, compared with £273,700 in April of last year, and with £123,200 in March of this year. The largest losses on the list or twenty-eight fires in which the damage reached £1,000 or more are—£60,000 at a furniture-dealer's and adjacent premises at Ipswich; £36,000 at a fire originating at a seed warehouse at Warrington; £35,000 at a mansion at Navan, Ireland; £30,000 at a phonograph works at Wandsworth; £23,000 at a shipbuilder's at Middlesbrough; £20,000 at a fancy-box maker's in Old Street, E.C. The other five-figure amounts in the list were—£16,000, bleach works, Manchester; £15,000, mansion, Lake, Wilts; £12,000, mill, Wakefield; and £10,000, mansion, Worksop.

OBITUARY.

Sir John Taylor, F.R.I.B.A.

Sir John Taylor, F.R.I.B.A., late of the Office of Works, died on Wednesday last at his residence at Surbiton Hill. He was born in 1833, the son of Mr. William Taylor, of Warkworth, Northumberland. He entered the Office of Works in 1859, and became a Fellow of the Royal Institute of British Architects in 1881. From 1866 to 1898 he was surveyor of Royal Palaces, Public Buildings, etc., in the Office of Works, and was afterwards consulting surveyor. He was created K.C.B. in 1897. Sir John Taylor was engaged upon some important buildings in London. The chief of these is the new War Office in Whitehall, where he carried out, in conjunction with Mr. Clyde Young, the designs of the late Mr. William Young. He was also responsible for large additions to Marlborough House, for the Record Office in Chancery Lane, the Bankruptcy Courts and offices in Carey Street, the principal staircase and central exhibition rooms at the National Gallery, Bow Street Police Court and Station, and the Marylebone, North London, and South-Western Police Courts.

Mr. J. J. Bradshaw.

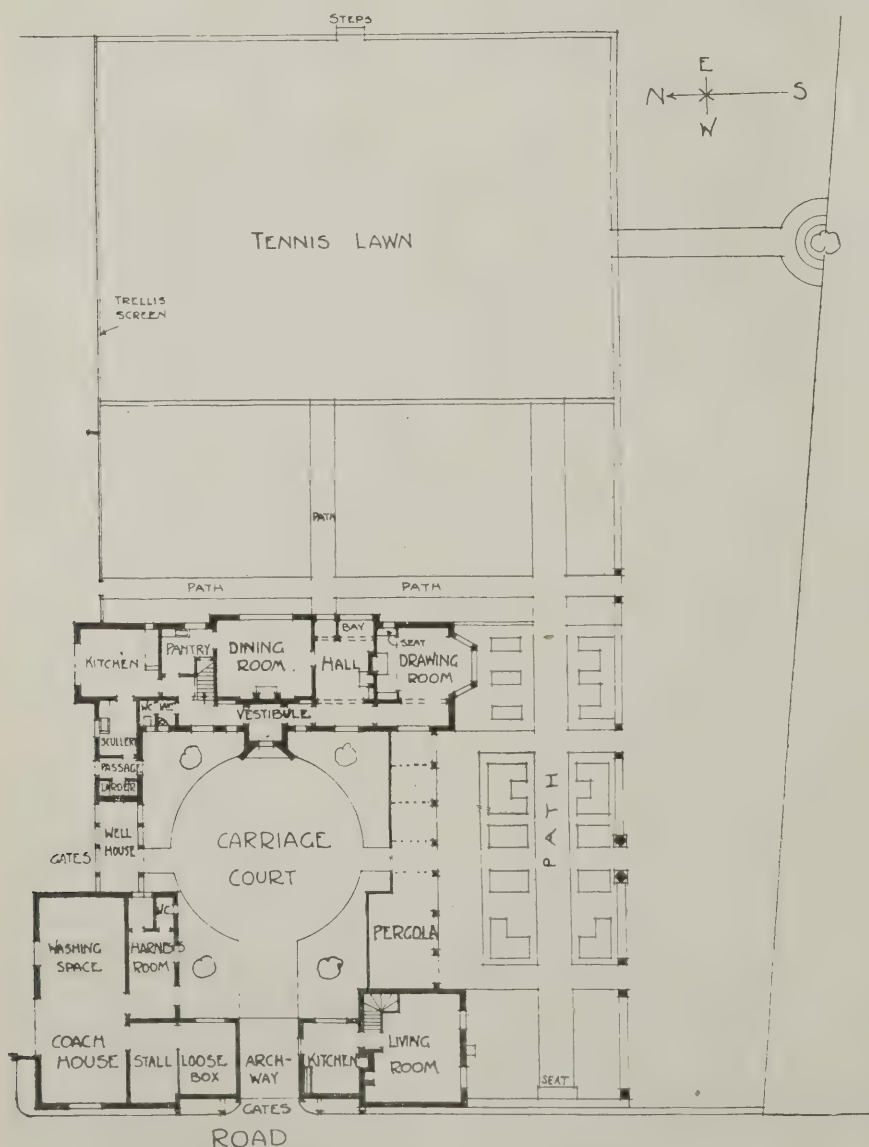

The death is announced, at Bolton, of Mr. Jonas J. Bradshaw, aged 76 years, the oldest architect in Lancashire. He was a Fellow of the Royal Institute of British Architects, and a member of the well-known firm of Bradshaw and Gass, which he founded. Mr. Bradshaw originated many improvements in the construction of cotton mills in Lancashire.

Mr. Frank Haviland.

By the death of Mr. Frank Haviland, which took place in London after a long and painful illness, we have lost an accomplished artist and versatile character at the comparatively early age of 42. Mr. Haviland was educated at the United Service College, Westward Ho! where he was within two or three years contemporary with Mr. Rudyard Kipling, while later, at the Nauenheim College, Heidelberg, he was a schoolfellow of Mr. John Hassall. He studied art at the St. John's Wood Art Schools and the Royal Academy Schools. In the early days of his career a portrait of Miss Constance Collier, hung "on the line" in the Royal Academy, attracted considerable attention. Mr. Haviland was a musician of considerable knowledge and executive ability, while the number of interesting models he has left behind him testify to his skill as a mechanical engineer.

Mr. C. Beresford Fox.

The death occurred on April 16th, in Toronto, at the age of 37, of Mr. Charles Beresford Fox, M.A., M.Inst.C.E., from the after-results of an operation for appendicitis. Mr. Fox, who was educated at Harrow and Trinity College, Cambridge, was, until his departure for Canada, a partner in the firm of Sir Douglas Fox and Partners. He had travelled round the world, and was then engaged as assistant engineer on the works of the Great Central Railway Extension to London. Afterwards he was in charge of the construction of the large bridge across the River Zambesi at the Victoria Falls for the Cape to Cairo Railway.

HOUSE AT GARBOLDISHAM, NORFOLK. P. MORLEY HORDER, F.R.I.B.A.,
ARCHITECT.

SOME NOTES ON "HY-RIB."

Architects and builders of the present day have at their disposal a variety of new materials and improved methods of construction, more especially in regard to the employment of steel in conjunction with concrete. In this country we rarely initiate, and are slow to take up anything new; there is, indeed, an ever-present conservatism which every inventor has to combat, sometimes in the form of personal prejudices, at other times in the form of laws and regulations. With regard to the first we may recall the prejudice, amounting almost to aversion, with which the average builder regards any new material or new method of construction; he has a tremendous tenacity for what he is accustomed to regard as the tried and accepted way of executing work. The new material and the new method, however, eventually force their own adoption, by reason of merits which, when demonstrated, can no longer be set aside, and thereafter the progress is rapid. Thus, architects and builders who were instinctively apprehensive of reinforced concrete when first introduced have since had abundant testimony to convince them of the excellence of such construction, and, having tried and tested for themselves, are now making the most extensive use of reinforced concrete; and similarly the building regulations of the London County Council, which persisted in requiring a reinforced concrete wall to be the same thickness as a brick one, though many times as strong, have had to be altered to meet the demands of the new method of construction. With some new materials, however, the merits are so self-evident, and the means of testing

DETAIL OF SHED FOR MIDLAND RAILWAY CONSTRUCTED WITH "HY-RIB."

them so simple, that they have only to be introduced in order to find immediate acceptance. This is so with "Hy-Rib"—a metal lath put on the English market some time ago by the Trussed Concrete Steel Company, Ltd., of Caxton House, Westminster, and now largely employed for all kinds of buildings. It is obtainable in three gauges of English steel, and consists of a punched lath bordered by a stiff rib. The width is 10½ in. and the standard lengths 6 ft., 8 ft., 10 ft., and 12 ft. The rib gives great rigidity—so much so, in fact, that when employed for partition

work there is no necessity for studding while for floors and roofs of concrete it serves the dual purpose of reinforcement and centering. The fact that it does away with the necessity for centering makes "Hy-Rib" a very economical material, and at the same time enables work to be carried out within the shortest possible time. The surface of the lath is dead true, and the mesh gives an excellent key with a minimum amount of material. The accompanying sections show the application of "Hy-Rib" for exterior walls built hollow and solid. The sheets are simply set up between the beams and plastered—in the case of hollow walls on the outer face only; in the case of solid walls on both sides. Internal partitions are similarly constructed, the ribs taking the place of studding. Thin but perfectly rigid partitions can be formed in this way, the thickness being only about 1½ ins. Such partitions are strong enough to withstand the blows of a sledge-hammer, and are fire-resisting. With regard to the latter, it may be mentioned that in a typical test with a 2 in. partition a fire of 1,700 degrees Fahr. was maintained for an hour and followed by the application of water from a hose, the result being entirely successful; the greatest deflection was no more than ¼ in.

Hollow Exterior Wall: Vertical Section.

Hollow Exterior Wall: Horizontal Section.

Solid Exterior Wall: Vertical Section.

TRAMWAY SHED, HULL, SHOWING
11-IN. "HY-RIB" WALLS IN COMPARISON
WITH 18-IN. BRICK.

"Hy-Rib" is applicable to all kinds of ceilings and roofs, especially curved forms. A particularly striking example of its use in curved ceilings is to be seen in the music room at Sir Edgar Speyer's house in Grosvenor Street, the architects of which are Messrs. Detmar Blow and Billerey. In the same way it can be employed for arched floors to carry heavy loads. Only enough concrete goes through to secure a firm grip on the steel, leaving the soffit with a good surface for plastering. The ease with which the material can be bent renders it adaptable also for coves and curved surfaces generally.

For bungalows, sheds, workshops, and similar buildings, "Hy-Rib" is very serviceable, and certainly is a great improvement on the corrugated iron formerly used so extensively for such purposes. The accompanying photograph of a bungalow at Howth, Dublin, is interesting as showing a building having reinforced concrete beams and piers with "Hy-Rib" walls between.

In this way 2 in. walls can be constructed which are fire-resisting, water proof, and dampproof, thoroughly rigid, and non-conducting, so that the rooms within are warm in winter and cool in summer. In the last respect they are admirable for buildings in hot climates. The accompanying illustration shows one such in West Africa.

The cost compares favourably with any other form of construction, and is less than that of many. That buildings can be built with "Hy-Rib" at remarkably low cost is shown particularly in the case of the phthisis hospital attached to Clayton Workhouse, near Bradford. This building, which accommodates 24 beds, cost no more than £1,200, the figure being thus only £50 per bed. The hospital

is built with hollow walls in the manner described above, the external face being pebble-dashed and the internal face covered with a hard polished patent plaster; and though it occupies a very exposed site the building has withstood the weather in a very satisfactory manner.

"Hy-Rib" is being largely used at the present time for gasworks buildings, tramway buildings, and structures of a similar kind; thus, at Bournemouth a retort house 110 ft. by 42 ft. by 65 ft. high has been entirely constructed with it, while in the tramway depot at Hull the difference between the 18 in. brickwork walls and the 1½ in. "Hy-Rib" is very noticeable (see accompanying photograph).

For architectural purposes the uses of "Hy-Rib" are innumerable.

LEGAL.

Builder's Claim Against M.P.

Judgment was delivered on April 25th, by Mr. Pollock, Official Referee, in a claim against Mr. H. C. Mallaby-Deeley, M.P. for the Harrow Division of Middlesex, for work in repairing and decorating his house, Mitcham Court, Surrey.

From the statement of claim it appeared that under a written contract dated May 20th, 1911, the plaintiff had agreed to do certain work and variations at Mitcham Court, which work was proceeded with; but before the completion of the contract the defendant repudiated and put an end to it, ordering the plaintiff to

leave the premises. The defendant admitted the agreement, but said that was entitled to put an end to it under terms because it was alleged that the plaintiff's workmanship was bad and the materials inferior, that the whole work was subjected to incompetent supervision and that it was not done to the satisfaction of the defendant's architect, Mr. Langton Cole, in accordance with the contract. Accordingly the defendant claimed to deduct £272 3s. 4d. from the plaintiff's claim in respect of defective work, and an additional sum of £54 as damages for delay.—Mr. Pollock, in the course of his judgment, said that the first question to be decided was whether, in the circumstances existing in August, 1911, Mr. Mallaby-Deeley was justified in putting an end to the contract with Mr. Sandon. There appeared to have been complaint made by Mr. Mallaby-Deeley about the work, but there were not any by Mr. Langton Cole, the architect. Mr. Langton Cole had given his evidence in a way which would be acceptable by any Court. Mr. Marshall and Mr. Adams, assistants in Mr. Langton Cole's office, had given evidence, and both said that the conditions in August were such that in the opinion Mr. Sandon could and would have been willing to put right all the matters complained of by the architect and this was important, because the work was to be done to the satisfaction of the architect under the contract. The Official Referee held that in these circumstances the defendant was not entitled to put an end to the contract, and that Mr. Sandon was entitled on a quantum

Bungalow at Howth, Dublin.

A Bungalow, West Africa.

"HY-RIB" CONSTRUCTION AS APPLIED TO SMALL HOUSES.

meruit in any case for the work he had done. With regard to the quality of the work, the Official Referee said he had himself examined it, and was satisfied that certain portions of the external painting justified complaint, and some reduction should be made in this respect. With regard to the internal work, Mr. Bankes, on behalf of the plaintiff, had practically admitted that some of it was not satisfactory; the only question was, therefore, what sum ought to be deducted from the claim? With regard to the question of delay, the question was what was its cause? Mr. Sandon contended that he could not get possession of the rooms he wanted in order to get his work done. Mr. Mallaby-Deeley said he could have had any room he wanted, but he (the Official Referee) was satisfied from the correspondence passing between the parties that Mr. Mallaby-Deeley must be mistaken with regard to this.—Mr. Sandon's claim, subject to any set-off for defective work, was £477. The Official Referee said he considered the counterclaim to have been much exaggerated; he did not propose to go into details, but to treat the matter as if he were a jury, as the parties had invited him to do, and he considered that £70 was a proper sum to deduct from the plaintiff's claim. There would be judgment for the plaintiff for £207, beyond the £200 paid into Court, which was to be paid out, on the claim and counterclaim, with the costs of the action.

Validity of an Architect's Certificate.

On May 1st the Court of Appeal, composed of Lords Justices Vaughan Williams, Fletcher Moulton, and Farwell, had before them the case of Ashwell and Nesbitt, Ltd., *versus* Allen and Co., on the appeal of the defendants from a judgment of Mr. Justice Coleridge. The plaintiffs, a Leicester firm, brought the action against Allen and Co., contractors, of Westminster, to recover £377 for work done and material supplied to a building in London under a contract dated May 12th, 1909. They claimed the amount under a certificate of the architect of the building, the owners of which were Lewis and Allenby. The defendants were the general contractors for the work, which was that of re-erecting premises in Regent Street at a cost of £28,000, and the plaintiffs were the sub-contractors for the installation of certain radiators and hydrants to the amount of £3,320. Plaintiffs alleged that there was a balance of £377 owing to them, and that this sum had been included in a certificate given by the architects to the defendants as main contractors. This, however, the defendants denied, their case being that at the time in question disputes were going on as to the number of radiators and hydrants put into the building, and that they had given the building owners large credits for a difference in the number supplied and those originally specified for. They further said that the architect issued the certificate for £377 without notice to them, and that in the circumstances they could go behind it.—Mr. Justice Coleridge gave judgment for the plaintiffs, and the defendants now appealed.—Mr. Hudson, K.C., on their behalf, said that the sole point was whether the certificate of the architect was valid. His submission was that the architect had completely abdicated his position as certifier.—Mr. J. B. Matthews, for the respondents, supported the judgment of the court below, submitting that the certificate of the architect was valid and binding, there being no

suggestion of collusion.—Their lordships allowed the appeal, holding that the validity of the certificate was so much in doubt that the action must go to trial on a *quantum meruit*.—Appellants were given the costs, both in this court and the court below.

R'S METHOD OF PERSPECTIVE.

R's method of perspective has been made familiar to architects through the energies of its inventor, Mr. R. W. Roberts, of 51, London Road, Ipswich. Represented by means of a series of diagrams, with descriptive letterpress, his publication has gone through ten editions, and is now considerably developed from the earlier form, the diagrams having several new time-and-labour-saving devices. The author claims that by his method perspective drawings can be rapidly and accurately made to scale without distant v.p.'s—hips, valleys, mouldings, etc., being shown with great facility; that the correct drawing of vaulting is simplified; that the Orders can be drawn in perspective more easily; and that details can be designed in perspective to a large scale. Rapid sketching to scale is also possible, the accompanying illustration serving as an example. Full particulars of the system can be obtained from the author.

TRADE AND CRAFT.

"Pudlo": A Damp-proofing Preparation.

In a humid climate like ours, where dampness is all-pervading, special precautions are necessary in order to prevent the intrusion of moisture where its presence is dangerous or undesirable. Indeed, a vast amount of patience and ingenuity must have been expended on the many and various means of contending with dampness. The latest of these is that which has been introduced under the name of "Pudlo." This is a chemically prepared white powder, which, when mixed with Portland cement to which the usual sand or aggregate is added, renders the concrete waterproof. The two questions that immediately arise are: (1) Does the powder fulfil its purpose? and (2) does it affect the strength of the cement? As to the first question a most convincing reply is found in the fact that, during the last 2½ years, several firms have repeated their orders for "Pudlo" seven or eight times. Many tons of the powder have been used in the construction of cement-block buildings; and, moreover, the British Government departments have shown full confidence in it, the India Office and the War Office having specified it; and we understand that it is being extensively used in the fortifications at Gibraltar. These facts indirectly imply a satisfactory answer to the second

PERSPECTIVE SKETCH OF DUNDEE TOWN HALL. MADE BY R'S METHOD.

question; to which, however, a direct and most gratifying reply is available in the assurance by the makers that Messrs. Faija, the eminent experts in testing, find that there is absolutely nothing in "Pudlo" which could act to the disadvantage of Portland cement, but that, on the contrary, it actually renders the cement slightly stronger, and therefore the better able to resist stresses.

"Pudlo" is adaptable to all kinds of waterproof renderings, and is useful for walls from which dampcoursing has been omitted, as well as for those which are specially exposed to the weather; and it is of proved value in preventing the flooding of cellars and basements. A further appreciable virtue of "Pudlo" is that it prevents the unsightly efflorescence which so often gives rise to dissatisfaction and misapprehension. The architect will be glad of the opportunity of avoiding this constantly recurring annoyance; but he will have still more reason for gratification in the means which "Pudlo" affords of preventing the far more serious contingency of damp walls and flooded basements.

Pudlo is manufactured in England by Messrs. Kerner-Greenwood and Co., of 201, St. Ann's, King's Lynn, who, with the object of saving correspondents the trouble of writing for information, wish to state explicitly that cement with "Pudlo" is just the same as cement without "Pudlo," except that the rendering of cement is absolutely waterproof when the powder "Pudlo" is mixed with it, and that the rendering or concrete will never show any efflorescence. Many people ask whether "Pudlo" makes the work greasy, or whether it affects the setting of the cement, and to all these questions the firm say—"No! The cement is just the same, whether the 'Pudlo' is in or not."

The "All-time" Dampcourse.

In our issue of November 8th, 1911, p. 486, we gave a description of the "All-time" dampcourse, which consists of two thin layers of fibrous asphalt sheeting between which is interposed a continuous sheet of lead-foil. The proprietor, Mr. Alexander G. Lee, 14, John

Street, Bedford Row, W.C., now forwards a list of recent Government and other contracts upon which this dampcourse has been employed. It is not possible to reproduce this list *in extenso*, but the following brief selection will sufficiently indicate the esteem in which the dampcourse is held by architects specifying for important contracts: War Office: Barracks, Whittingdon, near Lichfield; Shorncliffe Sub-district; Royal Marine Depot, Deal; barracks, Fermoy and Tralee. Admiralty: Dockyards at Portsmouth and Malta; magazines at Bedenham; extension to Lodge Hill Laboratory, Chatterden; Naval Cadet Training College, Osborne; new electrical shop, and gun-mounting shop, Portsmouth. Home Office: Prisons at Birmingham and Norwich. The "All-time" dampcourse has been used extensively in works for the Great Western Railway Company; for the Great Northern in the Corby to Essendine widening; and for the Metropolitan Railway's Baker Street improvements. It has been employed in schools 'or the Hampstead Garden Suburb, and in similar buildings at Watford, Knebworth, Boreham Wood, Liverpool, Somersetshire, Paisley, etc.; for hospitals at Earlestown, Tynemouth, etc.; for various churches; for Queen's University buildings at Belfast; and for the new State Offices in Guernsey.

REINFORCED CONCRETE BRIDGE, WITLEY, SURREY.

This bridge is constructed to connect two portions of Lord Pirrie's estate at Witley Park, Surrey, which are at this point bisected by a roadway known as Bowlhead Lane. It is provided with a high railing as well as a parapet on account of the deer which are allowed to roam freely from side to side. The bridge and the parapet are in ferro-concrete faced with Medusa cement. The capping and trusses are in Portland stone. The whole of the work was carried out by Messrs. Holloway Brothers (London), Ltd., the wrought iron railing which surmounts the parapet being by Messrs. F. Clubb and Son, of Hampstead, N.W. Mr. Edward Warren, F.R.I.B.A., F.S.A., was the architect.

Retirement of Mr. A. V. Nutt.

Mr. A. V. Nutt, the resident architect at Windsor Castle, is about to retire, after forty-four years' service. It was Mr. Nutt who designed the pseudo-Gothic annexe to Westminster Abbey for the Coronation of King Edward, and he personally supervised its restoration last year. His work at Windsor is no sinecure, for the task of maintaining the Royal residence in perfect repair, and in restoring the exterior as becomes necessary is no light one. The name of Mr. Nutt's successor is not yet known, but there is very keen competition for the post. Mr. Nutt will probably receive a knighthood on his retirement.

The Demolition of Buildings: Jury's Riders.

A verdict of "Accidental Death" was returned on Thursday last at the inquest on the bodies of three men who, on April 24th, were crushed to death by falling brickwork whilst demolishing a building used as a stores by the Gas Light and Coke Company on land at Battle Bridge Road, King's Cross, but the jury added the following riders: "That the Coroner be asked to represent to the authorities that an inspector be appointed in connection with the demolition of buildings; and, further, without attaching any blame to the contractor, we think that in the future breaking up of these arches the men engaged in breaking up iron and brickwork should be at a safer distance away from the actual demolition."

Architecture at the Paris Salon.

ARCHITECTURE at the Salon this year is without its usual central feature of a great set of restoration drawings from some student of the Villa Medici. There will be more of such exhibits in the future, no doubt; but evidently that kind of effort in the illustration of ancient architecture cannot be kept going

continuously. The most important set of drawings this year illustrates what appears to be an actual piece of work in process of execution, the "composition and architectural decoration of a French garden, on the lateral axis of the Château de R....;" the name of the place and the owner is not given, French proprietors having an objection to having their names published in an exhibition catalogue. The scheme seems to be that of an owner who aims at making a kind of private Versailles for himself on a small scale. It is illustrated by complete plans, sections of the ground, views, and details. The garden is a long design on a slightly sloping ground. Near the house is a square laid out in parterres, with a fountain in the middle; and off one side of the square opens a kind of semicircular open-air theatre with decorative arbours around it. Below the square, on the main axis, is a long sloping lawn bounded by trees on each side, and ending in a curved parterre and terrace flanked by pylons bearing equestrian statues. As a piece of decorative gardening it is a great scheme, such as is not often carried out as part of a private estate. M. Gréber is the architect.

As usual, there are a good many of those Utopian architectural schemes on a great, one might say an impossible scale, in which the younger generation of French architects love to indulge their imagination. The first thing we come to after ascending the steps from the sculpture hall is a scheme by M. Durand (pupil of M. Deglane) for a "monument to the glory of the independence of a great people"; the great people being, of course, the French nation. The centre feature of this is an enormous truncated obelisk, completely crushing the columnar order applied to its base, and sculptured on its face with a symbolical palm leaf, which, from the scale of the figures introduced, must be about two hundred feet high. Near this is a work somewhat more rational in its ambition, being a scheme prepared for the "Société pour le développement et l'encouragement des tous les Sports," aviation, of course, included. There appears to have been a site actually fixed on for the carrying out of this scheme, which includes a decorative garden with a pavilion in the midst, intended as a museum of everything connected with sport. M. le Mounier exhibits a design for "A permanent exhibition to the Glory of the Republic," a triumphal avenue leading to a crescent of buildings with a column in the centre; it is noticeable that all the symbols used in the decoration are of purely Roman character. M. Harant takes the half-ruined porch of Saint-Gille-du-Gard as the centre for a picturesque

grouping of imaginary Romanesque remains, doing for this school of architecture much what Pannini did for classic ruins; the experiment was, perhaps, hardly worth making. A rather interesting scheme is that by M. Carbonnier for the *aménagement* of the "Ile des Vierges" in the Seine, with plantations round the margin and an axial garden in the centre, with a circular *place* opposite the point where the bridge is placed, and another circular opening with a fountain at the other end of the garden vista. Another scheme is one by M. Giraud for "A Prefecture in the South of France," evidently a bid for a commission of the kind whenever the occasion arises. The Government might do worse, for the plan is really a very good one. To show that it can be arranged for any site, the author has even imagined an oblique line of road to which the façade has to be adapted; and he has had the novel idea of showing the principal elevation as it would appear both by day and night; in the latter case the lights of a reception at the Prefecture illumine the windows. This is an idea that might be carried further; to show that a building would look well by night as well as by day would be a new feature in the illustration of architectural designs.

To come to some of the illustrations of actual working architecture, this is illustrated chiefly in theatres and in

DESIGN FOR NEW CHURCH IN THE RUE DE VANVES, PARIS.

PIERRE SARDOU, ARCHITECT. (Salon, 1912.)

town and country houses. Church architecture is but little illustrated, modern church architecture that is to say, for the illustrations of ancient ecclesiastical architecture are numerous and often very fine; and it seems rather odd that while French architects take so much pleasure in illustrating ancient mediæval architecture they do so little in modern work that is at all like it; for French modern Gothic is a painful kind of business, concerning which the less said the better. The tendency is rather towards a kind of neo-Byzantine. M. Sardou's Parish church of Notre-Dame-de-Rosaire, at Paris, is an example; the drawing of the chancel shows a great brick chancel arch and plain brick walls with a timber roof, a Byzantine reredos, and a circular window at the east end. The west front, of which we give an illustration, has a good deal of character, though it will seem rather out of place among the usual types of Paris architecture. There is no other design for a modern church that is worth mentioning.

One of the best modern architectural designs is that by M. Martineau for the new theatre at Niort; apparently not the accepted one, which is also exhibited; but both plan and design of this are better, and one cannot

plan with a wide axial corridor, the offices being in a wing branching out at an oblique angle from a corner of the main block; this is a Gothic house—not very good Gothic, but better than that of the modern French churches; an arcade of pointed arches forms a loggia round two sides, and over the pointed-arch carriage porch rises a tower very like a Late Gothic church tower. Another still more important house at Buenos Aires is that designed by the well-known Paris architect M. Sortais, for a doctor at Buenos Aires. This is a house on an angle site, with a large circular hall forming the pivot of the plan. A corridor tangent, so to speak, to this circular hall forms at the other end a tangent, on the reverse side, to another circular hall. It seems an odd way of making a corridor enter upon a circle, but the plan as a whole is a somewhat remarkable one, and quite the reverse of commonplace.

The average-sized country house of France is, as our readers are probably aware, a kind of thing that is a terror to English taste. The French seem quite unable to appreciate the charm of simplicity and repose in a country residence, and to be a proper country "villa"

DESIGN FOR THEATRE AT NIORT. M. MARTINEAU, ARCHITECT.
(Salon, 1912.)

understand why the other was preferred to it. We give the ground-floor plan and principal elevation; it will be seen on the plan how effective is the treatment of the entrance hall. Among the designs for house architecture some of the most important are for Buenos Aires and other foreign sites. M. Dupuy (pupil of M. Laloux) exhibits an elaborate set of drawings for a "Ville d'Hiver" on the banks of the Parana. It looks like a kind of double hotel, a large rectangular block and a smaller square block, connected by a long pergola. The architectural details are not very good. The drawings give rather the impression of being a project only, they are so exceedingly ambitious; but some photographs of the work in progress (not very advanced, apparently) show that it is a practical scheme, or is so intended. M. Martin Noel's design for a villa on the Tigre (Argentine Republic) is finely planned to get rather a stately effect in a comparatively small house. We give the plan and principal elevation. The festoon decoration under the eaves, which comes out dark in the plate, is really painted on the wall surface in a warm buff tint. The architect is a native of Buenos Aires. Another house at Buenos Aires is a large one by a French architect, M. Fourniez, which has a rather fine

(a word only too appropriate in this case) a house must have enormous high-pitched roofs and be full of angles, elbows, projections, and tricks and dodges of all kinds. There are a good many of these at the Salon, and every one looks worse than the last. In many things we are inferior to the French in architecture, but in this point at least of good taste and repose in the style of our country houses we can certainly claim a marked superiority to them. The only country house design in the Salon on which we could look with any pleasure is M. Gagey's Villa of Heussaye, Côtes du Nord. This is a seaside house, boldly set on a high rock; and the exposed situation, apparently, has induced the architect to treat it in the most solid manner, with rubble masonry in thick mortar, with plain round-headed windows and chimneys with high square plain stalks. As a whole, this is a house which has the character suitable to an exposed seaside situation—strong and plain, and not bedizened with restless ornament; but it is rare to find such a design among the Salon country-house drawings. There is one design, however, not for a dwelling-house but for a dairy farm (*châlet de fromagerie*) in the Jura, in which the

picturesque form of the high roof is used rather successfully; the arrangement of the long slope of the roof seems to fall in naturally with the requirements of the building, which is treated very simply, and looks like what it is meant for—a farmhouse among the mountains.

There are two models among the exhibits at the Salon, both by the same architect, M. Demoriane; these are funeral monuments, and one of them is of special interest as being a monument to the late eminent architect Ginain. It is a most satisfactory design; the bronze bust of the late architect is placed on the top of a slightly pyramidal stele, the side projections of which turn round at the top into a kind of Ionic volute at each side, connected by a wreath which droops across the face of the stele. In front is the gravestone, with a simple cross worked on the top of it. The other monument, a family one, to be erected at Père-Lachaise, is a large alcove with a round barrel vault and coupled Ionic columns flanking the entrance; in the wall at the back is a cross worked into a circular pierced panel. It is closed in front by a pair of gilt metal gates of bold design.

Among the drawings which are illustrations of ancient work, one of the most interesting is a complete set of the ancient Byzantine church of Zeirek-Djambi at Constantinople by M. Adolphe Thiers (pupil of M. Pascal). This seems to be really three churches side by side, each with its apse; it is laid out with the most sublime disregard of parallelism or right angles, and has four domes sown over it anyhow, three of them elliptical on plan, one only circular. Another interesting set is that of the church of Saint-Thyrse, at Châteauvieux (Haute-Vienne); this has a Romanesque choir and transepts and a Gothic nave with no clear-storey, but on one side of the nave a series of small openings into the space above the aisle vault. It is an example of the odd things that are to be found in early French churches. The drawings are the work of M. Pontraud. M. Rauber's "studies of the ancient cloisters at Reims" are a fine set of drawings, tinted in Indian ink, of Romanesque detail. Then M. Roustan gives us a set of water-colour drawings of some of the

Ground-floor Plan.

A VILLA IN THE ARGENTINE REPUBLIC. MARTIN NOËL,
ARCHITECT. (Salon, 1912.)

ancient fountains of the Var district. These are all pretty much of the same type of design—a kind of urn supported on a thick stone stem rising out of a basin; they apparently represent a type of design peculiar to the country. M. Prieur exhibits a fine set of drawings of the tower and spire of Senlis Cathedral, including a detail drawing of the base of the spire with plans and sections. M. Bray, another pupil of M. Pascal, exhibits a drawing of "Le Grand-Orgue de l'Eglise Notre Dame de Moret." This is a drawing of an old sixteenth century organ-case, with open-work ornament of Renaissance character in front of the tops of the pipes. It represents the old organ in its present condition. Some of the front pipes are gone, and apparently the church has not been at the trouble to replace them. M. Gautier (pupil of M. Laloux) exhibits drawings of a most curious church, the chapel of Locquirec (Finistère). At the west end is a kind of double tower; a square tower linked with a circular one too large to be called a turret. The square tower has an open lantern on it in two bays, each containing a bell, and over this a short spire of quite Gothic character, with crockets up the angles, but which is definitely dated 1691. Without the written statement it would be difficult to assign a date to this odd mingling of styles.

Among other things noticeable we should not pass over M. Dumail's "Une école supérieure d'aviation militaire," for the sake of the excellent architectural design of the centre pavilion, a kind of revival of French eighteenth-century classic design; and also one of the "projects," by M. Delaon (pupil of M. Laloux), for a "station militaire, nautique et aéronautique." This is one of the

THEATRE AT NIORT. M. MARTINEAU, ARCHITECT.
(Salon, 1912.)

imaginary schemes, too ambitious to be ever carried out, but the principal elevation is a most impressive drawing, as an example of the effect of composition in strongly marked horizontal lines; it is powerfully tinted in a most effective manner, and is really a remarkable example of strong composition.

One of the most effective drawings in the architectural section is one by M. Hulot, giving a view of the gardens of the Villa Medici as seen from the Loggia, with the columns in the foreground. Whether by accident or intention, the picture-galleries of the Salon contain a large and fine painting by M. G. P. Leroux of exactly the same scene, "Diner dans une Villa Romaine," only that this is a twilight picture treated in colour and on a much larger scale.

The Drawings at the Architectural Association.

THE drawings which were exhibited at the Members' Smoking Concert on May 3rd, and which remained on view during the whole of last week, formed a remarkable collection, of special interest to students, because they were for the most part arranged on the principle of exhibiting photographs of executed work together with some of the working drawings from which the buildings were executed. Thus we had the representation of the work as completed, coupled with the drawings from which the finished result was brought about. There could not be a better way of studying contemporary architecture.

Among the sets of drawings one of the most interesting was Mr. Herbert Baker's for the Union Buildings at Pretoria. The plan is an exceedingly fine one, consisting of two rectangular blocks of buildings, symmetrically disposed on each side of the centre line, and connected by a grand semi-circular colonnade accentuated at each side by a tower and cupola at the junction with the rectangular blocks, each of which has a square columned hall as its centre. There could hardly be a better example of the dignified effect to be obtained by the symmetrical and axial disposition of a large building. Among the working drawings of detail elevation on a large scale were those by Sir Ernest George and Mr. Yeates for the Royal Academy of Music, those by Mr. Robert Atkinson for his design for the Manchester Art Gallery, and those by Mr. Greenslade for the National Library of Wales. Messrs. Forsyth and Maule exhibited the drawings of a brick church at Ijmuiden (if we read the name right)—we presume in Holland—showing among other details a mullioned and transomed window built up out of ordinary brickwork, the transoms forming flat arches. Among the smaller and simpler works was Mr. Spooner's chapel at Letchworth, a kind of brick Romanesque with a large circular window in the gable; and Mr. Curtis Green's very simple, almost barn-like church with a wooden roof designed on mediæval principles, in which the tie-beam is not a tie but a heavy beam supporting the part of the construction above it (picturesque but not scientific), and on which are supported, apparently, two carved wooden figures; the result is curious but certainly interesting. Mr. A. T. Bolton's house, "Hartwood Edge," showed a picturesque combination of rubble stone wall with brick strings and archivolt.

Among other drawings and photographs shown were some of domestic work by Mr. Ernest Newton, Mr. Guy Dawber, and Mr. Lutyens.

Besides the numerous working drawings there were some of the carefully prepared detail elevations of Sir Aston Webb's College of Science, and of the Admiralty buildings at the east end of the Victoria Memorial road, drawings originally prepared for exhibition at the Royal Academy, which we were glad to have an opportunity of seeing again.

There were many others which we have not space to mention specially; but the exhibition as a whole was a remarkable one, on which the Association is to be congratulated.

Proposed Gallery of Modern Foreign Art.

AN interesting newspaper correspondence is taking place with reference to the desirability of providing in London some permanent gallery of contemporary or modern foreign art, perhaps as an annexe to the Tate Gallery, which accords hospitality to British artists only, and is, therefore, as some suppose, lamentably incomplete as an exhibition of modern art. We want, in short, something akin to the catholicity of the Luxembourg. At present we incur the odium, as well as suffer the æsthetic consequences, of being too exclusively insular. It has been suggested that it would not be difficult to set aside or build a few rooms as an adjunct to the Tate Gallery, each room to be allocated to a particular country. "In this way," it is urged, "the British public would have an opportunity of learning something of contemporary foreign art, and of comparing the various schools with the British school." It is only in this way that due recognition of the unity of art can be made, and the art interaction between nations can become manifest. The present demand for greater eclecticism is probably an unconscious reverberation of the interest in foreign art that has been fostered by the trend of exhibitions at the various private galleries, but more particularly by the collections of foreign contemporary art that usually find a place at the White City and similar popular show-places. It is rather a scandal that London has not long ago extended to foreign art the hospitality of a permanent building. One consideration that may have militated against such a provision may have been knowledge of the fallibility of contemporary judgment in art. The picture that is to-day hailed as a masterpiece may to-morrow be despised and rejected. The Tate Gallery contains, consequently, many pictures that, famous in their hour, are no longer considered to be worth the wall-space they occupy. But while we are thus enlarging our borders, it would be worth while to make provision for an adequate collection of architectural examples, British and foreign; for while very few members of the general public would go out of their way to visit an exclusively architectural collection, there are thousands who would be glad to inspect it if it formed an adjunct to a public picture gallery.

The Question of Waterloo Bridge.

THOSE who are familiar with the congested state of traffic on Waterloo Bridge will agree that something very drastic will have to be done in the near future in order to get rid of the present state of affairs and put an end to the annoyance and loss of time caused to foot-passengers and vehicles alike. Waterloo Bridge is unquestionably the finest bridge across the Thames. There is a serenity about its design, massively carried out in granite, which makes it a noble object. We should be extremely sorry to see it superseded by a steel structure. At the same time the fact must be faced that its width is wholly inadequate to take the amount of traffic it now has to bear. Roadway and pavements both need to be double their present width. And if it come to a choice of two evils, far better have a mediocre bridge of ample width (like Westminster Bridge) than a splendid-looking bridge most inconveniently narrow. But surely the two ends could be secured by swallowing up the space known as Lancaster Place—a useless haven of roadway—and taking down one side of Waterloo Bridge to line with the existing block of houses on the west side. Thus we might still preserve the appearance of Waterloo Bridge, while making it wide enough to take the traffic. Its arches might very well be left alone, for the reason that the Thames is a highway for mere barges and tugs, which can pass through the present openings with ease: whereas some of the single-span votaries would lead one to imagine that passage had to be found for mighty ships.

ARCHITECTS OF THE DAY.

MESSRS. W. AND E. HUNT.

THE controversy as to what might form the basis of an English school of architecture, expressing the requirements and conditions of the present day, is an interminable one. The reason, perhaps, is to be found in the fact that architects in this country are too hesitating, too much concerned with hopes and fears, whereas in America—to draw a comparison—they know exactly what they want and they go direct towards their goal.

The last century witnessed a battle of the styles fought out with abundance of enthusiasm and acrimony, and if it may be taken that the Gothicists came out victorious, we cannot feel any satisfaction in the legacy that has come down to us. As applied to secular buildings, indeed, Gothic has gone right out of vogue, and we may be thankful that it has, for a more distressing type of building than that which was produced by the rank and file of architects who came after the first force of the Gothic Revival had spent itself could hardly be imagined. Later we were made familiar with a type of design called "Free Classic," a term meaning nothing in particular, and therefore well adapted to the hybrid architecture it stood for. A more respectable class of work was labelled as "carrying on the tradition of the English Renaissance." The character of this work seemed to be considered eminently appropriate for competitive designs for public buildings, and, as such, it might well be called English Competition Classic. It was certainly far better than the medleys it supplanted, but its merits were of a very mixed kind, for, while making abundant use of the Orders as decorative additions to buildings, there was no broad scheme underlying it, and it was generally associated with haphazard planning. At the present time there is a revival of Greek work, that is to say, the main lines of Greek work are accepted as the basis on which to form modern design. With this movement we have a great deal of sympathy, for the reason that those who are foremost in promoting it have a clear idea of what they are seeking after, and the work they produce exhibits ability of a high order. It is manifestly inappropriate to make mere replicas of Greek buildings, as was done at the beginning of the nineteenth century, when Nonconformist chapels were erected in the semblance of Greek temples; but the reasonable application of Greek forms in buildings of to-day is worthy of the whole support of architects. Among such as are working on lines like these we may take MESSRS. WILLIAM and EDWARD HUNT. A representative series of buildings designed by this firm of architects is

DETAIL OF STAIRCASE, No. 35, HARLEY STREET, LONDON.

here reproduced, and from these it will be seen that in their public buildings Messrs. HUNT have infused an essentially modern spirit into the Greek forms they have adopted as the basis of their designs. The building in Mortimer Street is a good example of this. Here we see a scholarly façade with the Order applied in a thoroughly legitimate way, while the detail shows abundant freshness. It is Neo-Grec work of similar character to Cockerell's, but with more liveliness. A good example of this is afforded by the doorway to No. 35, Harley Street, shown on the Centre Plate in this issue. This is an admirable piece of work—ample testimony to the claim that Neo-Grec need not be cold and formal.

Mr. WILLIAM HUNT and Mr. EDWARD HUNT both have strong ideas in regard to the relation of architecture to social life. It has been truly said that "out of a hideous city a hideous humanity grows," and surely the converse is true, so that a city formed of fine roads and beautiful buildings must tend towards an expanding nobility of thought and a higher view of life generally.

They are of opinion that the time has come when the Government of this country should consider seriously the idea of forming a Ministry of Fine Arts, which should control the general formation and the improvement of our cities and towns, and then the relationship of new buildings to such formation; while last, but not least, there should be a certain governance in regard to the exterior design of each separate building. They think that every city, town, county borough, or district could be represented by a small committee or committees of architects, and perhaps other persons of known artistic ability in regard to design, who, having the

EDWARD HUNT.

BUSINESS PREMISES, No. 93, MORTIMER STREET, LONDON.
WILLIAM AND EDWARD HUNT, ARCHITECTS.

building world after leaving King's College, London, and while studying architecture he joined his father at "Donington House," and is now in partnership with him. Some particulars of the buildings designed by them are given below:—

No. 93, Mortimer Street, London, W.

This building (a perspective of which is exhibited at this year's Academy) occupies the site of the old German Athenæum Club, and has been designed with the accommodation of two halls, the principal one being on the ground floor, with entrance from Mortimer Street through a corridor, on each side of which are showrooms and offices. The remainder of the building is planned for showrooms, offices, cloakrooms, and caretaker's quarters. The elevations are of Portland stone from the Western quarry, that to Mortimer Street having a shield charged with the Howard de Walden arms and other ornaments in bronze. The roofs are laid with U-section red tiles and green Westmoreland slates. The windows have wrought-iron casements, the circular roof-lights being also of iron. The whole of the construction is fire-resisting. Internally the building is finished with plaster, and joinery of oak. The pavings to the corridors are of white Pentelikon, green Tinos, and Corallo marbles. Pentelikon marble is used also for the staircase, which has a steel and bronze balustrade. The hall and other apartments on the ground floor are laid with oak-block flooring. Ventilation is controlled by a simple extract method with air-ducts from the ceilings, the hall in the basement having longitudinal ducts carried in the ground floor, communicating with extract flues rising to the roof. The heating is by a low-pressure hot-water installation, with radiators and pipes of wrought iron. The latter are taken in four circulations and carried through heat-resisting chases and ducts in the floors, the radiators being protected with steel and bronze cases.

HARLEY STREET
GROUND FLOOR.

BLOCK OF FLATS, No. 35, HARLEY STREET, LONDON.

work so much at heart, would be willing to serve without monetary reward, or at all events at a nominal fee, and before whom all exterior designs, including materials, would have to be passed before being carried out.

Education, they think, should proceed generally upon the lines of the Ecole des Beaux Arts, but arranged in such a way that domestic work and the design of buildings for business and other uses should have their place as well as large and magnificent projects.

Mr. WILLIAM HUNT, it may be added, started in practice in 1881 in the Adelphi, moving in 1897 to his present offices in "Donington House," Norfolk Street, Strand. During this time he had been responsible for a great amount of domestic work in various parts, including Hampstead, Fognal, Streatham, and in the West End. He is Justice of the Peace for the County of London, and represents Wandsworth on the London County Council, where he has served as chairman of the Main Drainage of London and other Committees.

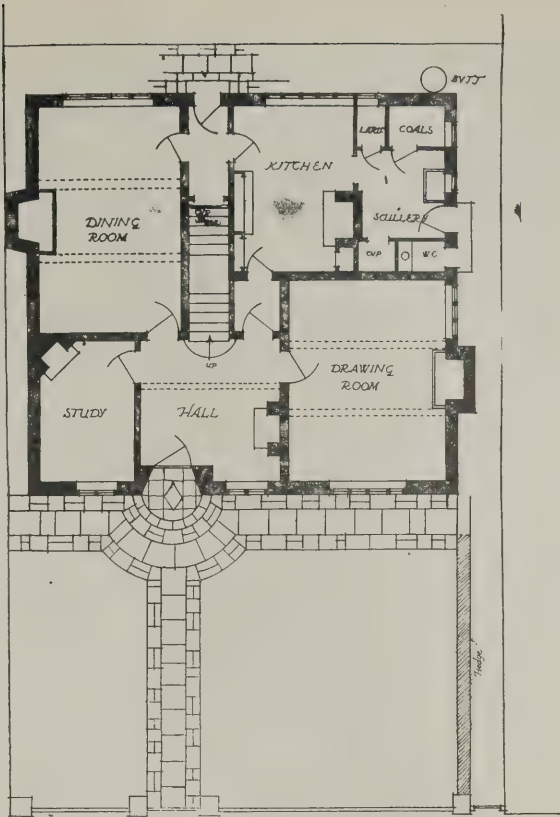

Mr. EDWARD HUNT, his son, became engaged in the

No. 35, Harley Street, London, W.

This is a block of flats, just completed. The building occupies a site at the corner of Harley Street and Queen Anne Street. The elevations are carried out in Portland stone, the main entrance having a little colour introduced by the use of blue Forest of Dean stone. The railings are of wrought iron, and the doors of oak with bronze fittings. Internally, the main staircase shows a simple treatment of white Pentelikon marble, with landings of that and other marbles, while the balustrade is of steel and bronze. The detailing throughout is very pleasing. A drawing of the building was shown at last year's Royal Academy exhibition.

Town House, Wimpole Street, W.

This house is not yet started. It is to be built of white Portland stone and 2 in. grey-red bricks with flat joints,

GROUND FLOOR PLAN

the roof to be of lead and grey-green slates. The casements will be painted a dove grey colour.

Business Premises, Old Bond Street, London, W.

These premises, now numbered 44, are a good example of what can be done, in skilful hands, with a narrow strip of frontage occupied by a shop on the ground floor and by offices above. The façade is carried out in Portland stone with wrought-iron windows and fanlights. The perspective view here reproduced was exhibited at the Royal Academy some years ago, and is itself a clever piece of penmanship.

Additions to the Balham Constitutional Club.

This little building was designed for use as an annexe to the club concert hall and smoking room. Externally it

is faced with hand-made red bricks with a wide flat joint. The entablature is in reinforced concrete, finished in stucco and coloured, while the windows and doors are of deal painted a cream tone. The roof is of glass with lead-covered iron bars. Internally the walls are finished with a simple plaster treatment of pilasters and panels, the floor being laid with dark red quarries.

"Redlands," Wimbledon.

This house, built for Mr. Charles H. Dewey, is situated close to Wimbledon Common. It is built of red hand-made bricks, with dark red tiles on the roofs. The casements are of wrought-iron with leaded lights, the frames being of deal painted white. The internal

arrangement is shown by the plans. The principal bedroom, dressing-room, bathroom, and lavatory are provided *en suite*, and shut off from the other part of the house. The walls are distempered, and the joinery is of Suffolk oak, wax-polished, the fireplaces being of red brickwork.

Group of Three Houses at Wimbledon.

These houses are to be built of rough stock bricks covered with stucco coloured creamy white, and having a slightly projecting base of hand-made bricks of a colour varying from deep red to dull purple, the quoins being similar. The window-frames are to be painted a cream tone and the doors bluish green.

"REDLANDS," WIMBLEDON: ENTRANCE.

WILLIAM AND EDWARD HUNT, ARCHITECTS.

"Redlands," Haslemere.

This house has not yet been erected. The perspective reproduced has been exhibited at the Royal Academy.

Cottage Flats, Putney.

These cottage flats, in Oakhill Road, are faced with 2-in. Dutch bricks, with a wide flat joint. The windows are of deal painted white and green, and the roofs are covered with dark red tiles.

New Municipal Buildings, Marylebone, London.

This was a design submitted in competition some months ago. It shows a dignified use of the Ionic Order, with just sufficient variety in the detail to give it interest.

PORTINSCALE BRIDGE AND THE GROUTING MACHINE.

PERIODICALLY a dispute arises over some old stone bridge in a country place which, by reason of its picturesqueness, has become endeared to residents and visitors. In these cases the usual statement is made, that the bridge is in a dangerous condition—generally because of the traffic of motor cars and motor lorries over it—and the ubiquitous local councillor overflowing with "good common-sense" is always eager to pull it down and substitute a steel bridge; thereby incidentally destroying some hundreds of years of association and at the same time providing something painfully out of keeping with the surrounding countryside. And when anyone suggests that there is no necessity to do so, he is told that his ideas are all stuff and nonsense. This is just what has happened in the case of Portinscale Bridge, in Cumberland. From all accounts this is an old bridge of much attractiveness, which, through modern wear and tear, has been rendered unstable. At the last meeting of the Cumberland County Council a motion was brought forward "that the County Council instruct their County Surveyor to proceed with the grouting of Portinscale Bridge according to Mr. Fox's report, and to raise the gradients on either side of the bridge as far as possible." This motion was eventually withdrawn on the understanding that the matter be left over till the end of the summer, and that meanwhile the Highways Committee should look after the bridge: but the point of the matter is, that the Chairman of the Council spoke of the resolution to grout the bridge as "the most preposterous ever brought before the Council." That the proposal is not in any way preposterous may be proved by a few facts about the grouting machine and its application. Opportunely we find these set forth in an article by Mr. Francis Fox himself in the May issue of *The Architectural Review*. First, it may be explained that the grouting machine, originally invented by the late Mr. Greathead for use in the electric tube railways of London, consists of an iron receiver or reservoir into which, by means of pumps, air can be forced under any pressure up to 100 lb. to the inch. This receiver is connected by a flexible tube to another portion of the apparatus called the "grouting pan," which is, in fact, a churn furnished with a handle and spindle to which are attached arms or beaters. The proper proportions of cement and water, and in certain cases sand, are then placed inside, the lid is screwed down, and the contents are churned up into the consistency of cream. This is now ready to be blown into the crack, the mouth of which on either side of the wall has meanwhile been clayed up to prevent the grout from escaping. The compressed air is then admitted to the grouting pan, and so soon as the necessary valve is opened the contents are discharged into the wall.

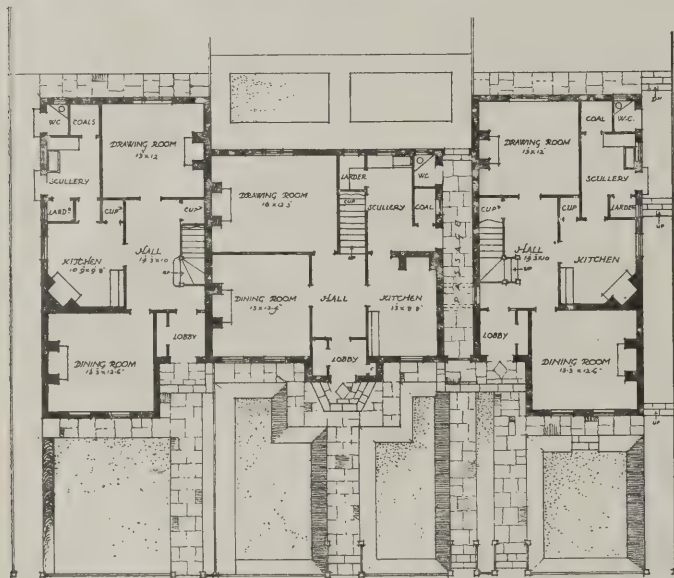

"Recognising the great utility and value of the machine," says Mr. Fox, "I decided to apply it to the saving of old buildings, and thus, having at command an apparatus by

WILLIAM AND EDWARD HUNT, ARCHITECTS.

which cement can be blown right into the heart of any structure, whereby all the loose particles of stone and the opposite sides of the crack can be agglutinated together, the power of repairing injured buildings without being compelled to pull them down is secured. The expense of grouting is very small, and does not generally amount to one-fifteenth or even one-twentieth of the cost of pulling down and rebuilding. From the æsthetic point of view the employment of this valuable apparatus is most important by reason of the fact that the appearance of a structure is not affected, not a stone has to be altered, and even the very moss can be left untouched."

It has been successfully used in many important old buildings, more especially churches and cathedrals, and has been applied with equal success to several old bridges. The charming bridges over the river at Grange on Derwentwater were in jeopardy to such an extent that when any vehicle passed over them the stones could be heard to move, and small pieces of stone and mortar trickled down in the interior. They were, however, subjected to treatment by the grouting machine, with this admirable result, that although the old appearance of the masonry was unaffected, not a stone being removed, the

GROUND FLOOR PLAN.
Scale of Feet. 0 10 20 30 40 50

FIRST FLOOR PLAN

bridges are to-day monolithic, and can be traversed by the heaviest traction engines. And the "Auld Brig o' Ayr" has been saved and made good for centuries to come by similar operations. So that there is nothing "preposterous" in the idea of grouting Portinscale Bridge, and we hope that the structure will eventually be preserved by this method.

An Architectural Entrance Scholarship.

A YEAR or two ago Professor C. H. Reilly, of the School of Architecture, Liverpool University, suggested to the Ravenhead Brick Co., of St. Helens, that they should wire-cut the face of their stock-bricks, as they already did the bed, and so modify the

texture by avoiding the splashes of alternate white and pink which come with the pressing. The firm in question took up the idea very keenly, and have now produced a brick with a good rough texture and colour at a price very little in advance of the ordinary stock-brick of the neighbourhood, which they call the Ravenhead Rustic Brick. These bricks have already won for themselves a large and ready sale, and, in acknowledgment, the Ravenhead Brick Co. have very generously offered to the School of Architecture an Open Entrance Scholarship of £30 a year for two years. They thus appear to have established an excellent precedent, for, apparently, this is the first entrance scholarship in any English school of architecture. It is open to anyone between the years of 18 and 23 on June 1st next, and will be awarded on drawings submitted, with an examination, if that is thought necessary. Particulars of the Scholarship are given in another part of the present issue.

CORRESPONDENCE.

The Editors disclaim all responsibility for the statements made or opinions expressed by correspondents. Correspondents are asked to be brief, and to write on one side only of the paper.

Registration of Architects.

To the Editor of the ARCHITECTS' AND BUILDERS' JOURNAL.

SIR,—In reference to the letter on Registration signed by Mr. A. W. S. Cross and Mr. George Hubbard, which appeared in your issue for April 27th, we shall be glad if you will be good enough to publish our letter to the R.I.B.A. "Journal," which appeared in the issue of that journal dated April 13th, and to which Messrs. Cross and Hubbard's letter is an answer.

ALBERT W. MOORE.
HERBERT SHEPHERD.

The letter which our correspondents desire us to reprint appears below:—

SIR,—Our Committee's attention has been drawn to a letter by Mr. Hioris published in the "Journal" of February 10th, in which he challenges the existence of a widely expressed desire in the profession for Registration. Such a view must be incomprehensible to those who have followed with interest the course of events which led up to the unanimous adoption by the Institute of the Registration policy in 1907.

For some years previous to that date the whole profession was deeply stirred by the subject, inasmuch as it was painfully conscious of the encroachments which were—and are still—being made on legiti-

mate interests of the profession by unqualified persons and trading firms. The agitation culminated in a demonstration of opinion at the Institute's elections, when the "Registrationists" emphasised the demand for such a policy by electing a Registration Council in place of that which had previously opposed their ideas.

In order to attest the opinion of the profession, [a professional journal] conducted a plebiscite which resulted in a very large majority of practising architects in the United Kingdom voting in favour of Registration as the policy which met their most pressing requirements. The Institute could not be blind to such a strongly manifested desire, and therefore appointed a very strong committee of leading members of the Institute, representing all shades of opinion in regard to this question. The committee reported that after holding fifteen sittings and hearing the evidence and views of twenty-four architects from various parts of England, Scotland, and Ireland, they were unanimously impressed with the desire of many architects (especially those practising in the provinces) that a legal status should be given to duly qualified practitioners in architecture, and they went on to express their belief that in a short time the holding of a legal diploma would prove of professional value, and that such State recognition would encourage education and raise the qualifications of architects, and would at the same time avoid the temporary necessity of granting a statutory title to unqualified men.

The committee's unanimous report is to be found in the "Journal" of March 9th,

1907, which also contains the plan suggested by the committee for carrying their recommendations into effect. This report was adopted by the general body of members, and in due course resolutions were submitted and carried unanimously by the general body of members in March, 1907. These resolutions have subsequently been referred to as the "Mandate," since the passing of which the whole profession has regarded Parliamentary Registration of Architects, under the auspices of the Institute, as a foregone conclusion; but, as in the case of all such reforms, the rank and file go for the broad principle of the measure, and leave the general details to the executive body. In the present instance the profession, more particularly the members of the Institute, have left the details by which registration is to be carried into effect in the hands of the Council with that confidence which is in itself a great tribute to them as a body. If this confidence is to remain undisturbed the Council should at the earliest possible moment produce a really practicable Bill based upon the principles laid down in the Registration Committee's Report of 1906.

We are conscious that we carry the weight of well-considered and responsible opinion when we state that no well-wisher of the Institute would like to see it torn into factions again, and the bitter fight and excitement of former times revived; neither do we wish to see the Institute stultifying its position by showing any hesitation in carrying out the solemn obligations which the resolutions of March, 1907, entrusted to the governing body.

ADDITION TO BALHAM CONSTITUTIONAL CLUB. WILLIAM AND EDWARD HUNT, ARCHITECTS.

That the President and Council are loyal to these resolutions was plainly manifested by the following statement of the President at the business meeting of March 9th: "The Council," he said, "do not consider that the question of registration is still an open question. We consider that the Institute and Council are bound by the resolutions passed on March 4th, 1907. As to the Council's proposals of January 8th, these having been referred back for further consideration, the Council have appointed a strong committee to consider the matter and report on the subject. The Council will in due course report to the general body."

As "Registrationists" we are, in common with other members of the Institute, also in sympathy with that policy, keenly waiting for that report, for after the experience of recent years we confidently anticipate that the committee will recommend a somewhat broader and more tolerant registration scheme, commanding the support of all interested parties, whether professional or educational, than that which has so far led to nothing being done of a tangible nature or calculated to inspire confidence among "Registrationists."

If, however, there should exist an opinion in the Institute that the registration policy is no longer generally desired by the profession, let such an opinion be tested by an attempt to rescind these resolutions. We are convinced that the result would show that the demand for such a policy is more firmly rooted than ever.

ALBERT W. MOORE, F.R.I.B.A.
HERBERT SHEPHERD, A.R.I.B.A.
Hon. Secretaries Institute Members' Club.

To the Editor of THE ARCHITECTS' AND BUILDERS' JOURNAL.

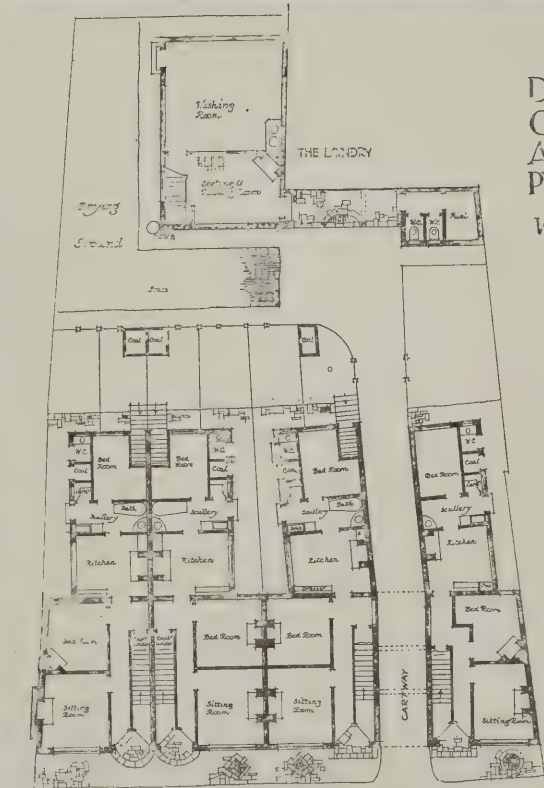

SIR,—You have been kind enough to publish one or two letters from us bearing, both directly and indirectly, upon the vital subject of Registration.

Some of our friends think that we have perhaps expressed ourselves more strongly than the circumstances warrant; but, to our minds, when we review the paucity of the results attained by the Institute after some five years' consideration, we are forced to the conclusion that the present serious position can only be satisfactorily dealt with by administering a drastic remedy.

The Institute, after much labour, has obtained a revision of its charter and by-laws so as to make it possible for the Society of Architects to be incorporated with the Institute. This labour has had a futile result, as the Institute, by a large majority, has now absolutely declined to sanction the incorporation of the Society. In fact, the compromise which was made between the Registrationists and anti-Registrationists has completely broken down, as was almost inevitable from its very inception.

No great cause has ever been won without a corresponding expenditure of energy, and we hope that the vast majority of the members of the Institute, who have the cause of Registration at heart, will not be discouraged by the fact that there is absolutely nothing to show for the immense amount of time which has been expended upon it.

Now is the opportunity to rub out the faint scratchings upon the slate which are generally unintelligible. What is wanted is a clean slate—on this should be mapped out in clear and unmistakable lines a programme framed to satisfy the members of the Institute, as well as all others whose

Ground Floor Plan

PUTNEY, S.W. for Mr. J. Purdy Esq.
William & Edward Hunt Architects.

claims are properly entitled to consideration.

There is no getting away from the fact that the combined wisdom of the members of the Institute must in the end evolve the only workable policy, and it seems to us that there is no other way of obtaining this combined wisdom than by holding a series of general meetings, in which provincial members are well represented. By this method clear and unmistakable lines may be mapped out on a clean slate, and then, and then only, will be the time for committees to be formed in order to give effect to the policy of the general body.

A. W. S. CROSS.
GEORGE HUBBARD.

The A.A. Athletic Club.

To the Editor of THE ARCHITECTS' AND BUILDERS' JOURNAL.

SIR,—The Council of the Architectural Association has very kindly given the general committee of the Athletic Club power to elect any member of the kindred professions—i.e., architecture, painting, sculpture, and surveying—as a member of the club. We should therefore be very grateful to you if you would kindly announce this in your valuable paper.

The club was founded in 1906, and, owing to its growing popularity, it was decided to purchase a ground of 6½ acres at Boreham Wood, Elstree, which is situated near the station and about half an hour

from town. The whole of this land has now been drained and levelled, and Rugby football, hockey, and cricket pitches have been arranged. We have also erected an excellent pavilion, with accommodation for changing, washing, and light refreshment.

The ground was formally opened last summer by Lady and Sir Aston Webb, and is considered to be one of the best in the county of Hertford. It has cost nearly £2,500, and I may say that donations to the ground fund are greatly needed.

The club has also rifle, swimming, and golf branches, all of which are very flourishing.

Gentlemen wishing to join the club should apply to me, care of the Architectural Association, 18, Tufton Street, Westminster.

JOHN H. SQUIRE,
Hon. Secretary A.C.

"What Might be Done with the Crystal Palace."

To the Editor of THE ARCHITECTS' AND BUILDERS' JOURNAL.

SIR,—In the issue of this Journal for April 17th (p. 391) some criticism is offered in reference to a scheme for utilising the Crystal Palace and grounds for a national folk-museum. I should be grateful for the hospitality of your columns for a brief reply; and in particular I wish to combat the doubts expressed as to whether a sufficient number of ancient houses still exist to render the scheme practicable. I believe such doubts to be wholly unfounded. It is quite certain that, notwithstanding the ruthless treatment to which our ancient houses and other buildings have been subjected in times past, there still remain a large number of sufficient merit, from their architectural features or historical associations, to warrant their permanent preserva-

tion. In the counties of Sussex and Kent (to speak for the moment of the area with which I am most familiar) there cannot be fewer than forty timber houses of the fifteenth and sixteenth centuries, any one of which, restored to its original form, would be perfectly suitable for re-erection in the Crystal Palace grounds as a part of the proposed open-air museum; and there are, besides, numerous ancient barns, water-mills, wind-mills, columbaria, well-houses, and other structures.

I hope that if the proposal to establish a national folk-museum (to include an open-air museum) be favourably received committees will be formed in various parts of the British Islands to keep a vigilant eye upon ancient buildings and monuments of all kinds, and to report upon such as are threatened with demolition or serious mutilation with a view to their purchase and removal to the open-air museum. The probability is not that there would be a dearth of suitable buildings, but that the limitations of space and of funds would preclude the saving of more than a small proportion of those that became available. The houses and other structures would not, of course, be left empty after their re-erection: they would be provided with furniture and appliances in keeping with their size, period, and locality, and thus become complete exhibits of some particular phase of culture.

The grounds of the Crystal Palace are extensive enough to enable the scheme for a national folk-museum to be carried out in addition to making beautiful gardens "with avenues, fountains, sculpture, parterres of flowers, and so on." But why should not these beautiful gardens be associated each with a beautiful house from some part or other of the British Islands? And why should not the grounds contain, besides a "garden of delight," a national playground where all our British sports and pastimes could be practised, and a national

open-air amphitheatre for the performance of old English stage plays and for folk-dances and songs?

I should be glad to send a copy of the scheme to any of your readers who may care to see it.

W. RUSKIN BUTTERFIELD,
Hon. Secretary, National Folk-Museum
Committee.
Brassey Institute, Hastings.

Architecture and Climate.

To the Editor of the ARCHITECTS' AND BUILDERS' JOURNAL.

SIR,—The editorial article on "The Architecture of the New Delhi," in your issue for May 1, makes one think, not only of the coming architecture of India, but also of that of England.

You consider—wisely, I think—that climate is an important factor in architectural design. You speak with truth of the difference between Gothic and Greek mouldings expressing the effect of the difference between northern and southern climates, and of the suitability of great cornices and open loggias or verandas for a sunny climate.

But your article seems to imply that the present-day architecture of England is especially suited to our climate, as if, when we obtained it from sunnier shores, we had modified it to suit our less fortunate conditions.

The revival of a Greek revival is considered by some to be playing an important part in modern English architecture, and, to judge by the centre plate in your issue of May 8, is receiving the guarded support of the R.I.B.A. Board of Architectural Education.

Are its devotees considering our climate as you recommend the designers of buildings for India to consider its climate?

Are they bearing in mind the suitability of the large rolls and deep hollows of

RADIATOR CASE, 93, MORTIMER STREET, W. WILLIAM AND EDWARD HUNT, ARCHITECTS.

DESIGN FOR NEW MUNICIPAL BUILDINGS, MARYLEBONE, LONDON. WILLIAM AND EDWARD HUNT, ARCHITECTS.

Gothic mouldings and of steep roofs and gables for the climate in which they were developed?

I think not, and I think it would be well if our students were encouraged to study such important factors in architectural design as the proper treatment of various materials, sound construction, sanitation, and suitability to purpose and surrounding conditions.

W. S. PURCHON.

The University, Sheffield.

Architects' Assistants and Registration.
To the Editor of THE ARCHITECTS' AND
BUILDERS' JOURNAL.

SIR,—I am requested to inform you that at the annual general meeting of the Guild of Architects' Assistants, held at Prince Henry's Room, 17, Fleet Street, E.C., on May 1st, the President of the Guild, Mr. A. W. S. Cross, M.A., F.R.I.B.A., in the chair, the following resolution was proposed by Mr. S. Douglas Topley, A.R.I.B.A., seconded by Mr. J. V. Hibbert, F.S.I., and carried unanimously: "The Guild of Architects' Assistants declares itself in opposition to the published proposals for the registration of architects, and calls upon its members and friends in the promoting societies to oppose any measure lacking complete provision for the interests of the pupil and the assistant." Copies of this resolution have been sent to the Royal Institute of British Architects and the Society of Architects.

ERNEST J. DIXON, A.R.I.B.A.,
Hon. Secretary, Guild of Architects'
Assistants.

137, Church Street, Edgware Road, W.

IN PARLIAMENT.

(By Our Press Gallery Representative.)

Architects at the Office of Works.

In the House of Commons Mr. Snowden asked Mr. Wedgwood Benn, as representing the First Commissioner of Works, whether the proposed staff of permanent architectural draughtsmen and technical assistants was intended to include all the men in the present staff classed and certificated as architectural assistants; and whether he would see that the misnomer "draughtsmen" formerly applied to these professional men but remedied, at the request of the class, to "architectural assistants" in 1907, should not be again reverted to.

Mr. Benn said: The answer to the first question is in the negative. Only those gentlemen who are eligible under the new scheme are intended to be included in the proposed new class. If there is a general

desire, the name of the proposed establishment can be altered.

Mr. Snowden asked what was the meaning of the phrase "who are eligible under the new scheme."

Mr. Benn said the scheme which was under consideration laid down certain conditions, and if those conditions were satis-

fied they would be asked if they desired to be included in the proposed new class.

Mr. Snowden asked if they had been asked already, but Mr. Benn could not say.

Mr. Snowden asked whether, in view of the undertaking made by his predecessor in this House on December 7th last that

DETAIL OF DESIGN FOR MARYLEBONE MUNICIPAL BUILDINGS.

the desires of all the class termed architectural assistants engaged in the Office of Works should be ascertained if they desired to be placed upon the established list, he was aware that no such inquiry had been made; and whether he could now state how soon this undertaking would be carried into effect.

Mr. Benn replied that so soon as the scheme now before the Treasury had been approved, the desires of all those gentlemen who were eligible for appointment to established rank as architectural or technical assistants, as the case might be, would be ascertained.

Mr. Snowden also asked whether Mr. Benn was aware that his proposal would lower the status of those professional men engaged for years in his department and termed and certificated as architectural assistants by their inclusion in the proposed staff of architectural draughtsmen and technical assistants; and whether he was aware that the professional ability and duties performed by this class were at the least equivalent to the class termed assistant architects, and therefore would he consider the justice of awarding in return equivalent conditions of service to all the class in question to that now granted to the assistant architects' class?

Mr. Benn, in reply, said: The First Commissioner is not of opinion that his proposal will involve any lowering of the status of those gentlemen, but if they object to the designation of architectural draughtsmen he is quite ready to style them architectural assistants. The honourable member is mistaken in supposing that the professional abilities and duties of these two classes are the same.

Victoria and Albert Museum.

Mr. Grant asked the President of the Board of Education whether he would now give instructions for the removal of the boarding recently erected over a considerable part of the permanent decorations of the north-western staircase in the Victoria and Albert Museum, which thereby destroyed the unity of that decoration; whether he would give instructions for the drawings, etc., which were at present hung upon the north-western staircase of the Victoria and Albert Museum to be removed to a more suitable exhibiting place in one or other of the better lighted rooms, now increasingly occupied by minor examples and purely experimental sketches; whether he would explain why the two stained-glass windows which existed on the north-western staircase at the Victoria and Albert Museum had been removed, thereby destroying the unity of the scheme of decoration; and whether he could see his way to nullify such an act of vandalism by ordering the windows to be replaced.

Mr. Joseph Pease, in a printed reply, stated: The stained-glass windows were removed primarily because they were dilapidated and required repair, which they are still undergoing. The question whether the balance of advantage really lies on the side of restoring the stained windows and removing the recently erected hoarding is largely a question of taste. I am not prepared to give instructions for the removal of the drawings now exhibited on the staircase pending a decision as to the general treatment of the staircase, on which I propose to take advice.

Mr. Grant asked if the President of the Board of Education would give instructions for making good and for the re-painting of the dilapidation of a small part of the ceiling in the lecture theatre gallery in the Victoria and Albert Museum, as well as for the walls of that gallery to be cleaned of the

accumulations of many years' dirt, so that they might be re-painted in a tint corresponding with that used when the scheme of decorating this gallery was originally carried out.

Mr. Joseph Pease stated that the making good and re-painting of the ceiling and re-colouring of the walls of the gallery had been in contemplation for some time, but the expense as well as the merits had to be considered.

Duke of York's Buildings.

Colonel Seely has informed Mr. Hoare that the alteration of the existing buildings at the Duke of York's headquarters will be completed by June 1st. There will, however, be some new buildings to be erected, of which some are already in hand and others will be commenced as soon as the designs and specifications are completed.

Walmer Castle.

Mr. Benn, replying to Mr. Snowden, who asked what arrangements had been made for the admission of the public to Walmer Castle and grounds, said the actual arrangements were being made by Lord Brassey, who had promised to grant facilities to the public for visiting the castle and grounds. The First Commissioner of Works understood that visitors would be able to see the historical rooms at all times of the year.

COMPETITIONS.

Cheshire County Council School, Port Sunlight.

We are informed that the Competitions Committee of the Liverpool Architectural Society are in correspondence with the Cheshire County Council with respect to the proposed competition for a school at Port Sunlight, and that members are requested to refrain from applying for the conditions at present, as the Society are pressing for the usual 5 per cent. commission and premium to competitors.

Padiham Municipal Offices Competition.

Members and licentiates of the Royal Institute of British Architects must not take part in the above competition, because the conditions are not in accordance with the published regulations of the Royal Institute for architectural competitions.—By order of the Council, IAN MACALISTER, Secretary, Royal Institute of British Architects.

King Edward Memorial, Ottawa.

Competitive designs are invited for a memorial to King Edward VII. to be erected at Ottawa by the Canadian Government, the competition being open to British subjects residing in any part of the world. Sketch models in plaster are required to the scale of 1½ in. to the foot. A sum of \$35,000 has been set apart for the work. Designs are to be delivered before October 1st next, and the awards will be made by a jury consisting of the Advisory Arts Council, namely, Sir Edmund Walker (Toronto), Dr. Francis J. Shepherd (Montreal), and Senator Arthur Boyer (Montreal). All communications regarding the competition should be addressed to the Secretary, Public Works Department, Ottawa, Canada.

LIST OF COMPETITIONS OPEN.

MAY 18. SUNK ARENA AND BAND-STAND, HASTINGS.—Corporation offer premiums of 15 and 10 guineas. Limit of cost, £4,500. Particulars, Town Clerk, Hastings.

MAY 22. COUNCIL SCHOOL, SOUTHEND-

ON-SEA.—Local architects are invited to submit designs for above building. Conditions and plans on application to J. W. Barrow, clerk, Education Offices, Municipal Buildings. Premiums: £25, £15, and £10.

MAY 25. PUBLIC OFFICES, LYMINGTON.—For second design, 30 guineas; third, 15 guineas. Mr. R. F. Gutteridge, F.R.I.B.A., is assessor. Apply to Town Clerk.

MAY 25. COVER DESIGN FOR A.A. JOURNAL.—The Editor of the Architectural Association Journal offers a first prize of two guineas and a second prize of one guinea for designs for the cover of the A.A. Journal. The President and Vice-Presidents will act as hon. assessors. Designs should be in Indian ink on white card, and should not be signed, but should be accompanied by a sealed envelope containing the competitor's name and address. They should be addressed to the Editor of the A.A. Journal, 18, Tufton Street, Westminster.

JUNE 1. INSTITUTE, NETHERTON, DUNFERMLINE.—Cost not to exceed £7,000. Premiums, £20, £15, and £10. Assessor, Mr. E. A. Jamieson. Apply, Secretary, Carnegie Trust, Abbot Street, Dunfermline.

JUNE 3. CRIPPLES' HOME, SHEFFIELD.—Local architects only. Assessor Mr. E. M. Gibbs, F.R.I.B.A., and Mr. F. E. P. Edwards, F.R.I.B.A.

JUNE 28. TOWN PLANNING, HALE.—Premiums of £50 and £25 are offered for a town-planning scheme. Address, Council Offices, Hale, Cheshire. [Note.—*Manchester Society of Architects have objected to the conditions. See our issue of May 8, p. 484.*]

JUNE 30. TOWN HALL, ETC., PADIHAM.—Premiums of £40 and £20 are offered for designs for town hall, baths, etc. Particulars, Mr. J. Gregson, A.M.Inst.C.E., Surveyor's Office, Padiham. [Note.—*R.I.B.A. have objected to the conditions.*]

JULY 1. NEW OFFICES FOR THE PORT OF LONDON.—Limited to the six architects selected in the preliminary competition. [See our issue of April 10, p. 370.]

AUGUST 6. FIRE STATION, CARDIFF.—Designs and estimates are invited by Cardiff Corporation. Assessor, Mr. A. Marshall Mackenzie. Particulars, Town Clerk, City Hall, Cardiff.

NO DATE. FIRE BRIGADE STATION, CARDIFF.—Cardiff Corporation invite architects to submit designs and estimates in competition for a fire brigade station proposed to be erected in Westgate Street, Cardiff. The Corporation have appointed Mr. A. Marshall Mackenzie, A.R.S.A., F.R.I.B.A., to act as assessor. Particulars on deposit of two guineas (returnable) from J. L. Wheatley, Town Clerk, City Hall, Cardiff.

DETAILS OLD AND NEW.—XL.

Doorway, Lloyds Bank, Hampstead.

Lloyds Bank, Hampstead, of which a detail of the doorway is shown on pages 510 and 511 of this issue, is built of Ham Hill stone with orange-red bricks supplied by Messrs. Thomas Lawrence and Sons, of Bracknell, Berks. The stone carving was executed by Messrs. Farmer and Brindley, of Westminster Bridge Road, S.E. The architects were Messrs. Horace Field, F.R.I.B.A., and Evelyn Simmons, Licentiate R.I.B.A. The building is a good example of modern work modelled on Georgian lines, the entrance doorway being particularly pleasing.

PRIVATE HOUSE LIGHTING BY
GAS.*

BY W. H. Y. WEBBER.

Having cleared up certain preliminary points relating to the correct control of burners, Mr. Webber proceeded to deal with the ordinary problem of planning a scheme of gas lighting for a typical suburban middle-class residence, such as would command a rent of £40 a year. First, as to the entrance hall and front door lighting. The conditions necessary to be observed are that the light shall fall on the face of anyone approaching the door after dark, while coming from well overhead and behind the person answering the door. If there is a flight of outside steps and a deep porch, it might be advisable to have a light projecting from the fanlight, but with an approach on the level the disposition recommended would require a medium power inverted lamp, clear underneath, in a not too "arty" lantern, which can be, if preferred, controlled by a switch in the wall, and will also light the doorways to the lower apartments and the lower flight of stairs.

For the dining-room the light must, of course, be concentrated upon the table. Its power will depend upon the size of the apartment and its shape, but it should not be less than 60 c.p. An adjustable pendant is indicated, which, when lowered, will provide ample light for reading by the fireside. It may be stipulated here that old-fashioned gas fittings for flat-flame burners, including especially the "water-slide" pendant accepted unquestioningly by the past generation, are quite unsuitable for incandescent burners. The increase of gas-pressure has rendered the latter dangerous. It can be converted, but is rarely worth it. Modern gas fittings are lighter and steadier than the old patterns. If preferred, a pair of smaller lights can be added beside the fireplace.

For the drawing-room, scattered small units are best. These can be either bracket lights, or dropped as short stiff pendants from the ceiling. A wall-light in the garden veranda is appreciated in summer-time, nor is it impracticable to extend the lighting into a shady nook of the garden.

In the kitchen, adequate lighting is necessary. A single pendant high up, or a pair to afford cross-lighting of the kitchen, will be appreciated by the cook. The scullery and back door can be served by a single flat flame.

On the stair-landing we want a watch-light as well as adequate illumination, and accordingly a flat flame, with Breeden's pilot for night use, is indicated. The same for the bathroom and w.c.

Pendants are most convenient for bedrooms, as permitting free arrangement of the big furniture. Dressing-tables should have the light coming from overhead, as nearly as possible in the same way as day-light, and cross-lights are preferred. A bed light is a great comfort. Single units will suffice for the smaller rooms. With all lights full on—a rare occurrence—the total consumption of gas would be about 50 cubic feet per hour. Under the old conditions it would be more than double for the same number of points. The increased amount of light would be as 4 to 1.

The ordinary lighting value of the modern unit is about treble that of the common flat flame. This speaks eloquently of the heightened standard of indoor illumination which has come into vogue with

the incandescent gas light. It could not have originated otherwise, seeing that, as already remarked, the colza oil and single-wick paraffin lamp does not give more than 15 c.p.; and the contemporary domestic standard incandescent electric lamp was of 8 c.p.

Pleasant household lighting is more a question of proper disposition of the lights than of mere candle-power, although the circumstance of having to allow in all cases a head-room of 6 ft. 6 in. from the floor is of itself a preventive of the bad placing of the lights too often seen in shop windows, with the naked illuminant in the line of sight. There can be no glare when the sources are well up out of the way. Although ordinary domestic lighting of middle-class dwellings does not permit of much range of fancy in the disposition of the sources, it offers plenty of scope in a modest way for the correct and tasteful choice of fittings and shades. There is seldom use for the more powerful units. If it is a sound rule, as I hold, that the power of the units or artificial light should be governed by the scale of the enclosed space to be lighted, then it follows that in the ordinary £40 a year house nothing more powerful than a medium-size inverted incandescent gas lamp, burning about 2½ cubic feet of gas an hour, and shedding a luminous intensity of between 50 and 60 c.p. in the lower hemispherical zone, is likely to be called for in any apartment. And only then if, as in the dining-room, a brilliant downward illumination is required. This paper is, as a matter of fact, being written by the light of such a source, which is ample for a cosy room about 13 ft. square, not counting window or sideboard recesses, although the walls are covered with dark brown paper and the furniture is black oak. The ceiling and a deep frieze are white, which is a wonderful aid to light diffusion. When the white table-cloth is spread, the brilliancy is quite enough for anyone.

Personally, I am no lover of indirect lighting by diffused reflection from a white ceiling, although I have secured a very pretty effect by suspending a Japanese umbrella under a ceiling lamp. I certainly do not admire the heavy, solid copper basin reflectors I have seen in use for a similar purpose. Complete opacity in the case of such reflectors is a mistake. To me, however, the shadowless lighting resulting from this treatment of home lights is unsettling to the nerves. I find myself drifting out of such a room to one where I can see the lamp if I want to. I believe that lamps, like other good servants, should be neither in the way nor out of the way.

One other form of light to which I object is the sham candle. I know it is a selling article, but that does not redeem it in my eyes. The real wax candle is a beautiful thing, and good candle-light is hard to beat. The colza moderator lamp, too, is elegant, which is more than can be said of most petroleum lamps. I do not admire the stiff, upright incandescent gas burner, while confessing its serviceability. The inverted incandescent lamp, however, with a well-chosen shade, can claim one's admiration of its form as well as our appreciation of its solid merits, and I am satisfied to leave it at that.

New Insurance Offices in Fleet Street.

New offices for the Norwich Union Fire and Life Insurance Society, Ltd., are to be erected at Nos. 48-52, Fleet Street, E.C., from designs by Messrs. Howell and Brooks. Messrs. Patman and Fotheringham, Ltd., have secured the contract.

JOTTINGS FROM PARIS.

Bank of France to be Enlarged.

A considerable extension of the Bank of France premises will probably cause the obliteration of the Rue Radziwill; but, in compensation, the Rue de Valois will be widened and lengthened.

Law as to Street Improvements.

The new enthusiasm for town-planning in Paris has secured a modification of the law of 1852 relating to street improvements. The new law gives full power to the administration to acquire and demolish any building which, either by its size or its appearance, interferes with the perspective or the æsthetic amenities of a street.

Official Changes.

M. Recoura has been appointed to the Bibliothèque Nationale in succession to M. Pascal, who has been appointed Inspector of *bâtiments civils*. M. Falcou, Inspector-General of Beaux-Arts of the City of Paris, has been appointed Director of the service of Beaux-Arts of the city.

Accidents to Workmen: Third-Party Responsibility.

A Parliamentary Commission, charged with investigating the desirability of modifying the law of 1898 with regard to accidents to workpeople, has decided that where the responsibility for accident appears to rest with a third party—that is to say, some person other than the employer or chief contractor—an action against such third party may be jointly brought by the employer and the injured person. Some such modification of the British law seems to be necessary in view of recent decisions, in one of which the chief contractor was mulcted in damages for an accident caused by a workman employed by a sub-contractor, in whose selection the principal contractor had no voice and over whose acts he had no control—a very curious anomaly of the law, which in this respect would seem to require immediate amendment. The same French Committee has decided that the compensation for persons under the age of twenty-one shall be based on the average wage of adult workmen in the same trade.

Increased Cost of Plasterwork.

The Chambre Syndicale des Fabricants de Plâtre have issued a circular to the effect that, owing to the continuance of the advanced prices of materials, the increased expenses of insurance and of transport, and other augmentations of outlay, they are obliged to make a corresponding increase in their charges for plasterwork, the extra charge being 1 franc per metre for contracts entered upon after December 31st, 1912; but, in order that existing contracts may not be unduly disturbed, the increase during the period between May 1st and December 31st, 1912, will be only half a franc per metre.

Cheap Dwellings Competition.

The Paris Municipal Council having voted 200,000,000 francs for the erection of cheap dwellings, the city authorities are arranging two architectural competitions referring respectively to (1) the Avenue Emile Zola, Rue Nouvelle, and Rue de Javel; and (2) Rues Henri-Becque and Brillat-Savarin. The former scheme requires five types of dwellings, with rents ranging from 200 to 550 francs; in the latter the rent is not to exceed 275 francs. The author of the first-premiated design in each case will be entrusted with the execution of the work, or will receive a premium, in the first competition, of 15,000 francs, and of 10,000 francs in the other. The further premiums are as follows:—First competition—2, 8,000 francs; 3, 7,000

* Extracts from a paper read at a meeting of the Illuminating Engineering Society, April 16th.

francs; 4, 6,000 francs; 5, 4,000 francs. Second competition—2, 6,000 francs; 3, 5,000 francs; 4, 4,000 francs; 5, 3,000 francs. The premiums are liberal enough to ensure keen competition, and the resultant designs will be awaited with much interest, as it is just possible that the French architects may show us a more excellent way of housing the working classes.

ROYAL INSTITUTE OF BRITISH ARCHITECTS.

Annual Report of the Council.

The R.I.B.A. report for the official year 1911-12 was submitted to the annual general meeting on Monday, May 6th. A few of the more important points in it are here given.

As we announced some time ago, it has been decided to award the Royal medal to Mr. Basil Champneys, F.S.A., in recognition of the distinguished merit of his executed work in architecture. His Majesty the King has graciously signified his approval of the award, and the medal will be presented to Mr. Champneys at the general meeting on June 24th.

The present subscribing membership of the Royal Institute comprises 859 Fellows, 1,581 Associates, and 56 Hon. Associates; total 2,496, as against 2,426 last year. During the official year since the last annual general meeting 13 Fellows have been elected, 108 Associates, and 2 Honorary Associates. The Council have decided to consider the situation which arises from these figures.

The period for the election of Licentiates having been extended to the end of June, 1912, applications have come in freely during the whole year, and at the present moment a total of 1,834 Licentiates have been elected, and many other applications are under consideration.

Since the publication of the last annual report, the Council have had the pleasure of admitting the Northamptonshire Association of Architects into alliance with the Royal Institute.

In the last annual report the Council outlined the steps that had been taken to secure united action by the Royal Institute and the Society of Architects in advancing the policy of registration. Legal and constitutional difficulties made it necessary to lay before the members a proposal to obtain the Privy Council's sanction for a Supplemental Charter and By-Laws conferring the necessary powers on the Royal Institute. The Council's proposals for this purpose were laid before a special general meeting on January 8th, 1912, and an amendment was carried referring them back to the Council for further consideration. The Council at once appointed a strong and representative Registration Committee to consider and report upon the question, and this Committee is now actively at work under the chairmanship of Mr. John Slater.

The Board of Professional Defence have given attention to several recent judicial decisions which have appeared to enlarge the legal responsibilities of architects, and the possibility of safeguarding the profession against hitherto unforeseen dangers is being carefully considered.

The Council are now considering the advisability of drawing up and publishing a Code of Professional Ethics for the guidance of members.

The Council have been engaged for some time upon the revision of the Schedule of Charges. The Councils of the Allied Societies in the United Kingdom have been

consulted in the matter, and it is hoped that the draft will be ready for submission to the general body at an early date.

During the past year the Town Planning Committee has been in communication with the Allied Societies with the object of bringing architectural opinion to bear on the town planning schemes that are being prepared throughout the country. It has already prepared and published a pamphlet for the guidance of promoters of such schemes.

The Henry Jarvis Bequest is now in the hands of the residuary trustees, and the Council have advised them, under the terms of the will, to apply the available income to the foundation of Jarvis Studentships at the New School at Rome. If the Council's proposals are accepted there will be an annual examination for the studentship, which will be open to all Students and Associates of the Royal Institute of British Architects under the age of 30 years, and one studentship will be awarded every year, of an annual value of about £180 and tenable for two years.

During the presidency of Sir Ernest George the Council gave much consideration to the possibility of founding a British School of Architecture at Rome. A Special Committee was formed to consider the project, and had entered into negotiations with the authorities of the existing British School at Rome. The Council therefore welcomed the intervention of the Commissioners of the Exhibition of 1851, who came forward at a critical moment and, with the assistance of the Royal Institute, the Royal Academy, the Royal Society of Sculptors, and the British School at Rome, founded and endowed a new and enlarged School of Painting, Architecture, Sculpture, and Archæology, which will soon begin its work. The Royal Institute of British Architects is represented on the Council of the new school by Mr. Reginald Blomfield and Mr. John W. Simpson. At the request of the Commissioners the Council have prepared a scheme for the examination of the candidates for the Architectural Scholarship which will be awarded every year by the Commissioners, and it is intended that the holders of the proposed Jarvis Studentship should also be in residence at the new school for a period of two years each.

The Joint Committee on Reinforced Concrete has compiled and published, with the sanction of the Council, a Second Report on Reinforced Concrete. It has also considered the London County Council's draft regulations for Reinforced Concrete Construction, and has reported upon them to the Council, who have submitted various criticisms and suggestions to the Local Government Board, whose sanction is required for these Regulations.

The Practice Standing Committee report, *inter alia*, that the sub-committee which had been engaged on the question of revising the Schedule of Charges, and had very carefully dealt with the suggestions made in reply to the circular sent out by the Council to all members of the Institute, had presented a report. The proposed new schedule drawn up by them, after being carefully considered by the committee, was forwarded to the Council with an urgent recommendation for its adoption at as early a date as possible. The importance of removing some of the admitted deficiencies of the existing schedule is emphasised by the fact that, of the large number of difficulties arising in practice which have been brought before the committee, at least one-third have dealt with questions of professional charges.

As an outcome of many difficulties experienced by members, arising out of the use of the R.I.B.A. Conditions of Contract, of recent legal decisions affecting the liability of architects under these conditions, and of certain suggestions made by Messrs. Edwin T. Hall and Max Clarke, the Council, towards the end of last session, referred to the committee the question of the advisability of amending the existing Conditions of Contract and especially the clauses dealing with P.C. amounts and provisional sums. The committee appointed a sub-committee to deal with the matter. During the current session a very large number of additional difficulties arising out of the existing conditions have been brought before the committee, and these have in most cases been referred to the sub-committee, the scope of whose reference has accordingly been considerably extended. Arising out of these questions the committee, on the suggestion of the sub-committee, have recommended to the Council the desirability of obtaining a legal opinion on the relative duration of architects' and contractors' liability under the Statute of Limitations. This has only just been received, and is now being considered by the sub-committee. The sub-committee have presented an interim report, and it is hoped that their complete report may be presented by the end of the Session.

It having been brought to the knowledge of the committee that the London Master Builders' Association is endeavouring to draw up a form of agreement between contractors and sub-contractors, a special meeting of the Committee was held at which a deputation from the Association was invited to be present. The chairman, secretary, and several members of council of that body, accordingly attended. They explained the difficulties at present existing in regard to the subject and the direction in which they were trying to overcome them. A general discussion followed, in which a useful interchange of views took place.

The Science Standing Committee report that they have now finally approved the suggestions of the District Surveyors' Association governing the deposit of drawings and calculations with District Surveyors in connection with skeleton frame buildings. These suggested regulations have been published by the District Surveyors' Association. The committee report also their proceedings with regard to research on building materials, mortar tests, the use of English timber, and other matters.

SHEFFIELD SOCIETY OF ARCHITECTS.

The annual meeting of the Sheffield Society of Architects and Surveyors was held at the University recently, Mr. J. B. Mitchell-Withers presiding.

The Hon. Secretary, Mr. James R. Wigfull, presented the twenty-fifth annual report. Referring to Sheffield's new building by-laws, Mr. Wigfull said there was a want of elasticity in their provisions, while too great a desire to conserve the old methods of building was evinced, and too little encouragement given to more modern methods and materials. Referring to the competition for plans for the Sheffield King Edward Memorial Cripples' Home, he said that the conditions for the competition had been issued, and the Council hoped that the response would be such that the local authorities would be encouraged to follow this example and again place some of the designing of public buildings of the city in the hands of architects in private prac-

NORTHERN ARCHITECTURAL
ASSOCIATION.

tice. Such a course would promote a spirit of healthy rivalry, from which the city would derive benefit. The Council had had under consideration, continued Mr. Wigfull, various proposals with regard to the width of roads, especially with a view to their modification in circumstances where they are not main thoroughfares and where only a few houses are served by them. A suggestion by Mr. Sandford that on hilly sites, where terrace roads are formed, these should be of half the usual width and have houses on one side only, met with general approval; but it was felt that this proposal dealt only with part of the problem so far as Sheffield was concerned and that in such circumstances as those indicated above a general reduction in the width of road was desirable.

It was reported that the past year had seen the credit balance of £60 reduced to £38 and in accounting for this Mr. Wigfull said it was not so bad as it appeared to be, as the Society had paid during the year two contributions of £25 (for two years) to the Sheffield University.

The election of officers for the ensuing year resulted as follows: President, Mr. J. B. Mitchell-Withers (re-elected); Vice-President, Mr. A. F. Watson (re-elected); Hon. Treasurer, Mr. R. W. Fowler; Hon. Secretary, Mr. J. R. Wigfull (re-elected); Council, Messrs. W. G. Buck, F. E. P. Edwards, C. B. Flockton, J. R. Hall, C. F. Innocent, H. L. Paterson, H. I. Potter, E. Winder, and F. H. Wrench.

A selection from the prize drawings of the R.I.B.A., 1912, was on exhibition.

TYNE AND BLYTH DISTRICT
BUILDING TRADES FEDERATION.

The annual meeting of the Executive Council of the Tyne and Blyth District Building Trades Federation was held at the County Hotel, Newcastle-on-Tyne, on April 29th.

After the usual routine business had been settled, Councillor J. T. Armstrong was re-elected president, Mr. J. Simpson (Blyth) vice-president, and Mr. William Brown (South Shields) honorary auditor, and the usual trade committees were appointed.

The annual report having been presented and adopted, the question of the annual subscription was discussed and determined.

A report upon the last meeting of the Plasterers' Trade Committee was presented, having particular reference to a complaint against the employment of those other than plasterers to do certain work which the plasterers claimed as belonging to their trade, namely fixing and filling in plaster reverse moulds for the production of cast *in situ* cement work, and the necessary cleaning off of same. The following resolution had been passed at that meeting: "That this meeting considers the work done *in situ* of the moulded cement cornice or coping should be carried out by plasterers, and recommends [the employer concerned] to carry out his work accordingly. It is understood that in the absence of bricklayers this meeting cannot pre-judge generally any question of demarcation of work which that trade may have in common with the plasterers."

A letter was read from the Newcastle Association asking that as the local committee had been unable to settle a dispute, the Conciliation Board be called together to consider the reference which dealt with the notice and counter-notice in connection with the proposed alteration to the Newcastle stonemasons' working rules. It was decided to call the Board together at a given date.

The report of the Council for the fifty-third session shows a decrease of ten—223 against the 233 of last year—in the total membership, and this is assumed to be a consequence of the continued depression in the building industry. The falling off is chiefly in the class of Associates—88 in 1911 as against 95 in 1910—and this is accounted for by the numbers who have left the country or have relinquished the profession. During the year three venerable and distinguished members of the Association died—namely, Mr. J. P. Pritchett, Mr. G. G. Hoskins, and Mr. W. Glover. The first-named died at the age of 81, the second was 74, and the third 82. Mr. Glover was a generous benefactor to the Association, having given £1,000 towards the purchase of permanent premises; the interest on £1,000 for the foundation of the Glover travelling studentship, etc.; £25 and many books to the library fund; and many pictures and drawings, etc. During the year the rules were revised, and were sanctioned and approved in January of the present year by the Royal Institute. At the request of the Corporation of Newcastle-on-Tyne, the Association appointed two members to attend meetings of the sub-committee of the Corporation formed for the purposes of Part II. of the Housing and Town Planning Act. The Council of the Association, acting on the advice of the Practice Committee, have asked the Royal Institute to consider the following suggestions with respect to the appointments of clerks of works: (1) That such appointments in future be made by the architect; (2) that power of dismissal should rest with the architect; (3) that the salary be paid through the architect. Further suggestions have also been made to the R.I.B.A. with reference to the proposed amendment of the schedule of professional charges.

NEW BOOKS.

The Insurance Act and Yourself.

In order to arrive at a fair understanding of even the shortest and simplest Act of Parliament the layman requires the assistance of a legally qualified interpreter, and the necessity for expert guidance is greatly magnified in the case of a complicated measure like the Insurance Act. In "The Insurance Act and Yourself" (London: Thomas Murby and Co., 6, Bouverie Street, E.C.; price 6d.) Mr. Horace B. Samuel, M.A., Barrister-at-Law, provides an admirably popular exposition of the Act, not only making its provisions clear, but discussing them in all their bearings in such plain language as to render the book quite interesting to read, as well as being explicatory and instructive.

Columns and Struts.

Mr. William Alexander's book on the theory and practical design of columns and struts is distinguished beyond most technical manuals by the extent to which original and independent investigation is included. Euler's formula leads to the conclusion that a strut of uniform section throughout passes into a state of indifferent equilibrium when it commences to bend under an axial load, and therefore that no relation can be determined between the load and the amount of deflection. This conclusion, erroneous through the rejection of certain factors, has formed, says Mr. Alexander, a barrier to progress in the investigation of column and strut phenomena. Accord-

ingly he has made his own investigations on different lines. He demonstrates the true relations between load and deflection and bases the resulting equations on the maximum permissible amount of deflection, that limiting amount being, in turn, determined from the maximum permissible fibre stress intensity. Further, the nature of the shearing or web stresses is shown and their amounts are determined directly from the equations to the curves of deflection and not, as is usual, from an imaginary equivalent transverse load. He shows that the form of the cross-section has a great effect on the strength of a strut, and the efficiency of common sections is discussed in detail. The general effect of tapering in columns and many details of design are considered, and there is a detailed investigation of the struts which were the first to fail in the Quebec Bridge disaster. In the last chapter a large number of problems in design are worked out in illustration of the correct application of the principal equations required for practical designing.

Concerning a passage in the report of the Royal Commission on the Quebec Bridge failure the author makes, as it seems to us, a rather inept observation. The report says:—"The professional knowledge of the present day concerning the action of steel columns under load is not sufficient to enable engineers to economically design such structures as the Quebec Bridge. A bridge that will unquestionably be safe can be built, but in the present state of professional knowledge a considerably larger amount of material would have to be used than might be required if our knowledge were more exact." Upon this Mr. Alexander comments:—"That statement appears to be somewhat illogical, as, if it is not possible to determine the correct amount of metal required in a strut, how could it be known that the amount used was greater than necessary? On the other hand, if it could be known that the amount used was greater than necessary, why put in so much?" Question for question, why should Mr. Alexander waste space in chopping logic? There is no real dilemma. What will break is roughly known and what will not break is roughly known, and you naturally use what you know will not break, although you are well aware that you are probably exceeding the exact amount necessary, that amount being unascertainable. Surely there are cases in which the designer may know whether or not he has a margin, without being able to determine its exact measurement.

Columns and Struts. Theory and Practical Design. With examples worked out. By Wm. Alexander, M.Inst.C.E. 101 illustrations. Pp. xii. + 268, 8½ in. by 6 in., price 10s. 6d. net. London: E. and F. N. Spon, Ltd., 57, Haymarket.

The West Country.

"The Homeland Reference Books," cheap, compact, well illustrated, and compiled with great care, deserve the remarkable success that they have undoubtedly achieved. The volume dealing with "The West Country—Somerset, Dorset, Devon, and Cornwall"—of which we have received the 1912 edition, is one of the best of the series. All the interests of the West Country—historical, scenic, architectural, practical—are clearly and accurately represented, and all necessary guidance in the practical details of travelling, hotel accommodation, places of worship, amusements, and other matters is conspicuously set forth. Several maps are included.

The West Country: Somerset, Dorset, Devon, and Cornwall. Pp. 254, 7½ in. by 5 in., price 1s. net. London: The Homeland Association, Ltd., 15, Bedford Street, Strand.

NEWS ITEMS.

Mr. Norman Shaw.

Mr. R. Norman Shaw, R.A., celebrated his 81st birthday on May 7th.

Windsor Castle Architect and Surveyor.

Mr. R. B. Robertson has been appointed architect and surveyor at Windsor Castle, in the place of Mr. A. Y. Nutt, M.V.O., who has retired under the age limit.

Lectures on Concrete Engineering at Cambridge.

The lectures on practical and theoretical concrete engineering have now been resumed at the Cambridge University Engineering Laboratories, the lecturer being Mr. A. C. Davis, of the Saxon Cement Co., Cambridge.

Notice of Removal.

The London showrooms of Messrs. J. and R. Corker, Ltd., of Rotherham, have been transferred from Saracen's Head Buildings, Snow Hill, to Atlantic House, Holborn Viaduct, and 49, Farringdon Street, E.C. (Mr. W. B. Clarke, London director.)

Sheffield Garden Suburb.

The Sheffield City Council have before them a scheme for laying out a garden suburb at a cost of £60,000. The Council acquired much of the land in the Rivelin Valley and made a road through it. The land fronting the road is now to be laid out for building under the direction of the Council.

Town Planning Act Amendment Bill.

A Bill to amend the Housing, Town Planning, etc., Act, 1909, presented by Mr. Cassel, and backed by Viscount Wolmer, Mr. Duke, and Mr. Worthington Evans, has been printed. It seeks to substitute appeal to a court of quarter sessions for appeal to the Local Government Board under sections 15, 17, and 18 of the Town Planning Act.

The New Building of the Royal Society of Medicine.

The new building of the Royal Society of Medicine at the corner of Henrietta Street and Wimpole Street, W., is to be opened by the King and Queen on May 21st. The architects are Messrs. John Belcher, R.A., and J. J. Joass, F.R.I.B.A., and the builders Messrs. G. Godson and Sons, of London, W. "Ceresit," supplied by the British Ceresit Waterproofing Company, Ltd., of 68, Victoria Street, S.W., has been used for waterproofing the structure.

The Bacon Memorial at Gray's Inn.

The statue of Francis Bacon which is to be erected in South Square, Gray's Inn, will be unveiled on June 27th by Mr. Balfour. The statue is the work of Mr. F. W. Pomeroy. The simple inscription on the front of the pedestal will be: "Francis Bacon—1560/1-1626," but on another side will be set forth the dates which mark his connection with the Inn—"Admitted, 1576, called to the Bar 1582, Reader 1588, Dean of Chapel 1589, Treasurer 1608-1617." Bacon was the last Treasurer of the Inn who held office for more than one year in succession. The date selected for the unveiling of the memorial, June 27th, is that upon which he was admitted to the

Inn and called to the Bar. Upon another side of the pedestal will be a list of Bacon's principal works, "The Essays, Instauratio Magna et Novum Organum; History of the Reign of Henry VII., De Dignitate et Augmentis Scientiarum." The fourth side will recite the public offices held by Bacon: "M.P. for Middlesex 1593, Solicitor-General 1607, Attorney-General 1613, Lord Keeper 1617, Lord Chancellor 1618."

To R.I.B.A. Associates.

In view of the recent discussion at the business general meeting of the R.I.B.A. on March 4th on the question of the representation of Associates on the Council, it has been suggested that it would be of great assistance to the Council and to members if accurate information could be obtained as to the number of Associates who are qualified for the Fellowship, but who have remained in the Associate class. The Council will therefore be glad if all those Associates who have reached the age of thirty years, and have been in practice for seven years as principals, will kindly send their names to the Secretary.

The New A.R.A.

Mr. William Llewellyn was elected an Associate of the Royal Academy last week. Mr. Llewellyn was born in 1863. He entered the Kensington Training School in 1881, when Sir Edward Poynter was Principal, and afterwards worked in Paris under Ferdinand Cormon and also in one of Julien's ateliers visited by Lefebre and Ferrier. He has been a regular exhibitor at the Academy since 1886. Mr. Llewellyn has also exhibited at the New Gallery. He is a member of the Royal Society of Portrait Painters and of the Society of Twenty-five Painters.

This year the Academy exhibition will remain open every Thursday evening until 10 p.m. at the usual charge of 1s. for admission.

Structural Stability of the Leaning Tower of Pisa.

"The Leaning Tower of Pisa is not, we think, in immediate danger; nevertheless hurry up with your preventive measures if you wish to avert another such catastrophe as that of St. Mark's Campanile." Such, in substance, is the conclusion which the Royal Commission experts have just presented to the Italian Government. The worst menace to the safety of the famous structure is due to the presence of strong currents of fresh water athwart the base of the tower. These currents undermining the foundations must have already created notable hollows in the subsoil, and, what is more serious, no effectual means have hitherto been devised for checking them.

OBITUARY.

The Late Mr. Harston.

Mr. Arthur Harston, of Hackney, N.E., architect and surveyor, who died on April 6th, aged seventy-one, left estate which has been proved at £48,986 gross.

Mr. Herbert Holloway.

The death is announced of Mr. Herbert Holloway, contractor, of Wolverhampton. Mr. Holloway, who was 60 years of age, from a small beginning nearly forty years ago built up a very large business and carried out extensive tramway, water, and sewerage schemes.

VENTILATION BY OZONAIR.

On Friday last a large party of technical experts and others were conducted, under the guidance of representatives of Messrs. Ozonair, Ltd., over a section of the Central London Railway for the purpose of inspecting the Ozonair system of ventilation with which the railway has recently been equipped throughout. The installation consists of a separate and independent plant at each station, with the exception of Shepherd's Bush, which is near to the open end of the tunnel. The operation of a plant is as follows: A filter screen cleans and washes the incoming air from all dirt and smuts, at the same time absorbing all the deleterious gases, such as ammonia and sulphurous acids. The air is drawn through a filter screen by the aid of a fan, which is driven by a powerful electric motor. This screen is kept moistened by means of a continuous flow of water from a series of jets at its upper edge. A comparatively strong mixture of ozone is produced by the ozone generator, and this is conveyed by a pipe to the mixing chamber of the main ventilating fan, where it is mixed with the main current of air and thence blown down the main air-trunk to the various distributing sheet-metal ducts or conduits on the platforms. Most of the Central London Railway equipments each pass normally some 360,000 cubic feet per hour, and the generator provides an amount of ozone sufficient to preserve the proper proportion. The proportion of ozone and the volume of air supplied can be regulated from the switchboards controlling each equipment. The main ventilating fans are of the "Sirocco" pattern, being driven, in most cases, by $7\frac{1}{2}$ h.p. motors. The installation on the Central London Railway has given complete satisfaction, the purified and invigorating quality of the atmosphere throughout the entire system being at once apparent.

PROPOSED MUNICIPAL WORKS.

The Local Government Board has decided to hold, or has recently held, as the dates indicate, inquiries into proposed expenditure by public bodies as follows:—Barking Town Urban District Council, £10,000 for housing (May 14th). Sewerage, drainage, and sewage disposal—Kettering Rural District Council, £5,900 for Corby (May 16th); Sutton-in-Ashfield Urban District Council, £1,366 (May 16th); Birmingham Tame and Rea Drainage Board, £56,000 (May 17th); Widnes Borough Council, £3,000 (May 17th); Wrotham Urban District Council, £10,000 (May 17th); Droylsden Urban District Council, £1,157 (May 16th); Lichfield Rural District Council, £10,139 for Shenhall (May 15th); Ossett Borough Council, £3,453 and £1,650 (May 15th); Cannock Rural District Council, £5,200 (May 14th). Street improvements, etc.—Droylsden Urban District Council, £5,556 (May 16th); Blackpool Borough Council, £2,224 (May 15th); Leeds City Council, £24,767 (May 14th). Various—Ebbw Vale Urban District Council, £12,000 for carrying out Education Act, 1902, and £4,000 for electric lighting (May 16th); Worksop Urban District Council, £6,470 for electric lighting (May 17th); Chester City Council, £14,839 for hydro-electricity works (May 16th); Blackpool Borough Council, £10,000 for plant at electricity works (May 15th); Cudworth Urban District Council, £6,700 for gas undertaking (May 14th).

Church Architecture at the Royal Academy.

WE never remember such a large proportion of church designs as there is in the Academy Architectural Room this year. The whole of the long wall of the room is occupied with them; and as there is not really any special activity in church architecture at present, it looks rather as if the Hanging Committee

had admitted all the church drawings sent, to the exclusion of others, with the view of making a feature of church architecture in this year's exhibition.

There is so much room for new ideas in church architecture at present—they are, in fact, so much needed—that one looks at such a collection with some interest to see if it will afford anything of the kind. There is not much new suggestion; the majority of the designs follow what is still the usual type of revived mediæval building. There can be little doubt, however, that the mediæval type of church will not very long be accepted as all that can be done for a modern church; many architects go on designing such churches, as sanctioned by custom; but the question as to the suitability of the mediæval plan for modern worship is being much canvassed; and then there is the question, too, of the architectural value of revived Gothic. For everything except churches Gothic seems now to be out of date; it still clings to the church; but for how long?

Mr. Ambler's church at Potter's Bar, the first on the list, boasts of a plan, but is hung too high to make much out of it, save that it appears to be a red brick church in regulation Gothic style, with stone dressings and a short square tower at the crossing. There is nothing to object to in it, nor in Mr. Doyle's church for Mossley Hill, Liverpool (no plan), regulation Gothic, with a western tower. Mr. Gibbs's St. George's Church, Madrid, is interesting as a church on Spanish ground by an English architect; it does not take on any Spanish character, but it is good Gothic, forming a picturesque group, with well-proportioned buttresses. The interior is hung in another part of the room, and has a sexpartite vault, a form of vaulting not much patronised in revived Gothic, any more than it was in ancient Gothic. Two drawings of the same building should surely be hung together, but it is one of the vagaries of the Architectural Room that this is hardly ever done. Mr. Tapper's School Chapel for Perth, Australia, takes the orthodox form of a school chapel. In the Private Chapel at Pull Court, Tewkesbury, by Mr. Anthony Wilson, we get away from Gothic for a moment; this is no doubt a chapel in a house in Renaissance style, and looks rather like a large drawing-room, with Classic pilasters and a segmental ceiling, and a black and white marble floor laid in a very obvious kind of pattern; nothing about it symbolises a chapel except the altar at the end. The exterior of Messrs. Walsh and Nicholas's St. Matthew's Church, Northowram (Halifax),

shows the unusual arrangement, in an English church, of a tower standing separate from the church, connected with it by a roofed passage; a plan might have shown better the reason for this; it is a good building, but the tower seems to finish very abruptly with a set-off coping; it looks rather as if it wanted a spire to complete it.

Mr. Fellowes Prynne's interior view of St. Martin's, Worcester, has more character than anything we have come to yet; the piers are octagonal, with arches springing from them with no capitals intervening, piers and arches in brick alternating with stone, and a panelled wooden dado round the base of the piers; it is shown in an excellent water-colour drawing. Below this hangs a large coarsely executed drawing of part of an open work memorial screen by Messrs. Bromet and Thorman, with a quasi-Gothic tracery that does not gain in effect from having the fillets set out at different widths. This drawing could have been perfectly well seen if hung at the top of the wall space, whereas here it is unnecessarily hung close to the eye, while small drawings are hung high where they cannot be seen—another example of the want of common sense with which the contents of the Architectural Room are arranged. In the interior of St. Faith's, Nottingham, Mr. Sudbury seems to have wished to show what could be done with mere round-arch arcading and wall arches without a scrap of decorative detail, and with a quarter-pitch rafter roof. There is character, certainly, in this stern simplicity, shown in an effective drawing. Mr. Cogswell's Rood-screen at St. Andrew's, Exmouth, is one of the few really original pieces of design in the room. Gothic in feeling, but with no imitative detail, the piquantly designed uprights and brackets carry a screen divided into square and narrow panels alternately, each narrow one containing a statue. The interior of St. Andrew's, Coulsdon, by Messrs. Greenaway and Newberry, is of the solid Gothic order. In this and their other interior, St. Peter's, South Wimbledon, they show a true perception of the quality of masonry design. In both of these, again, the arches develop out of the piers without any capitals. There is a recent tendency to employ this method of treatment. Capitals in Gothic are going out of fashion, and no doubt it is difficult to find an original treatment for modern Gothic capitals.

Mr. Honan's interior of St. Philip Neri, Liverpool, a small drawing, is hung too high to see anything except that it shows that awkward arrangement of round side-arches cutting into the section of a rounded barrel vault, producing disagreeable and distorted curves, which ought always to be avoided. Another small drawing hung too high to be seen is a "design for a church" by Mr. Marvin, which appears to be a rather clever design for a church of mediæval composition, but with something like free Classic detail. A suggestion of that kind is worth consideration, and deserved to be hung where it could be seen; while on the other hand we find a space given, on the line, to a large coarsely executed drawing called "Sketch for an Abbey Church," a mere piece of late Gothic commonplace.

Mr. Carøe's Church of Stanley St. Peter, Wakefield, is shown in a large beautifully executed interior view. Here again the capital is omitted; the lowest member of the arch comes down the side of the pier as a projecting fillet; a similar fillet on the other face of the pier runs up to a cap carrying the wall-piece of the timber roof. No plan is given. The next exhibit, St. Joseph's Church, Aldershot, by Messrs. H. R. & B. A. Poulter, shows an exceedingly effective piece of planning to fit a triangular site at the junction of two roads at an acute angle. With true architectural perception, the architects have derived the character of their plan from the peculiarity of the site; developing the plan in steps, as it were; first a small chapel, then a long Lady-chapel parallel with it, running out as far as the site boundary permits; then the main church, which runs out to the extremity of the site. The elevations show a brick church based on Byzantine models. This is one of the best things in the room. Mr. Carøe's St. Boniface, St. Budeaux (Devon), is a large and effective exterior with a western tower, in which we notice again the method of stopping the tower off square at the top by a level coping. This abrupt finish seems to be a new fashion in tower design; it has rather a crude appearance. Messrs. Grove and Gill's St. Mark's, South Teddington, is a small exterior perspective of what appears to be a church with some originality of treatment, and therefore is, of course, hung so high that one can hardly make it out; the west-end tower appears to be a long-shaped octagon on plan, with the longer axis at right angles to the axis of the nave; it appears to be very effectively treated. In Messrs. Kelly and Dickie's St. Saviour's, Lewisham, we have the unusual spectacle of a Renaissance church interior with an arcade on columns, and a round-arched barrel vault accentuated by ribs dividing the bays; between these the round-headed clearstory windows cut into the vault with the distorted curve which we have already referred to in another instance. The complicated design of Mr. Wolstenholme's Congregational Church, Fairhaven, absolutely requires a plan to explain it, though that could not reconcile one to the character of the detail.

A few numbers further on we come on a view of the interior of Messrs. Poulter's church at Aldershot, put far away from the plan and elevations, with the usual carelessness in the whole arrangement of the Architectural Room. This is a very characteristic interior, with square brick piers alternating with frankly Byzantine columns. The inner face of the brick piers is continued as a wide pilaster up to the cornice, the whole covered with a semi-circular wooden barrel vault. In the case of alternating piers, principal and intermediate, in the nave arcade, there should be, to make the scheme complete, a corresponding alternation in the roof design, as there is in so many of the ancient Romanesque churches with alternating piers. Mr. Tapper's Church of the Annunciation, Old Quebec Street, is a fine solidly treated brick Gothic exterior; for once the interior view is placed next to it, but is less interesting. Mr. Matear exhibits a large and important elevation drawing of the west end of Holy Trinity Church, Southport, accompanied by a plan and a half section of the tower, which is the principal object in the elevation. This is the right sort of drawing to send to the Architectural Room, and we wish there were more such, though we confess that we cannot in this case feel very enthusiastic about the design in itself. It is loaded with a good deal of elaborate detail for which there hardly seems a sufficient motive. This is, we imagine, a new west front and tower to an already existing church. Messrs. Lofting and Cooper's St. Luke, West Hartlepool, is an exterior view of an Early English church, accompanied by a rather unusual plan, the nave being almost an exact square. The piers shown on the plan do not seem quite adequate to carry the centre tower. Mr. Burke Downing has got a good deal of character into the west end of his brick church at Mitcham, for the City of London School Mission.

Mr. Temple Moore exhibits the plan and two line-drawing perspectives of what he frankly describes as "Rejected design for the Chapel of the Community of the Resurrection, Mirfield." The plan is an interesting and very unusual one. There is a short nave expanding into a wider nave. There are two small chapels fitted obliquely into the re-entering angles of the chancel walls with the east ambulatory wall. There are other peculiar and interesting features of planning; but the promise which the plan seems to give of an interesting and effective exterior and interior architecture is hardly fulfilled by the rather heavily drawn perspective views, the effect of which seems rambling and uncertain.

Professor Beresford Pite exhibits a large perspective view, accompanied by a plan, of the interior of his Uganda cathedral, in which there is a great expenditure of tie-rods in all directions to secure an arched construction carried on columns with decorative capitals of peculiar and original design. We presume there is something like a central dome, as a squinch arch is visible on the opposite side of the central space. Any building carried out by Professor Pite will be sure to be original and striking, but we feel a certain dislike to arched construction depending on tie-rods. A building should be built, not bandaged.

Mr. Maurice B. Adams's interior view of the Chapel of All Souls', Bedford Park, is of interest, as, if we read the drawing aright, it appears to represent a modern application of the method of vaulting employed in the old Romanesque church of Tournus, a series of arched vaults at right angles to the long axis of the building, built up between transverse arches. If so, it is the only modern example we remember to have seen of this method of vaulting. The drawing is a highly finished perspective in ink line, no doubt by the architect, whose accomplishment in this respect is well known. There are a great many finely executed drawings in the collection, but no very many, we imagine, the work of the architects whose names they bear.

On the whole, one cannot say that this large exhibition of church designs contains a very great proportion of work that is of real interest. Church architecture for the most part seems still to run too much in a kind of accepted groove; indeed, there are some designs, bearing good names, too, which we passed over because there was really nothing to say about them except that they were correct Gothic, of the kind that might have been built any time since the Gothic Revival. Our own impression is that the basilica form of church is really the best for modern worship, or, at all events, that it lies between that and the Byzantine type of plan with a wide central area, and we should like to see more attempts made in either of those types. The central area covered by dome is, of course, liable to be acoustically defective; but acoustics are not everything, or even the chief thing, in church design.

The Parthian Palace of Hatra.

THE subject of the lecture given at the meeting of the Society for the Promotion of Roman Studies on May 14th, hardly came properly within the scope of the Society's programme, since it dealt with the remains of the Parthian Palace at Hatra, and the Parthians were exactly the people who refused to be conquered by the Romans or incorporated under their empire. However, no one could complain, for the lecturer was Miss Gertrude Bell; and to hear Miss Bell lecture on an ancient building, and to see her photographs of it, is to be sure of an intellectual treat. The palace at Hatra is a most curious example of the strange things that happened in what may be called the debatable lands of architecture. The palace consisted, in plan, of two main apartments, vaulted in stone (portions of the vaults still remaining), and with a narrow compartment on each side, the vaults of which

served as abutments to the larger central vault. Among the curious details illustrated in the photographs were the capitals of the pilasters, decorated by a row, or in some cases two rows, of stiff and clumsily modelled leaves ranged side by side and drooping over at the top, looking like an attempt to imitate the Classic acanthus. A still more peculiar detail was the decoration of some of the pilasters with small heads rudely carved in relief, generally two together near the top of the pilaster, standing out from the stonework without any moulding or margin round them, but as if stuck on to the wall: a kind of detail of which there seems to be no other example. Some of the vaults showed the system of heavy stone arches supporting a lighter filling between them—a form of roofing found in various old churches in Syria, and also in the late Roman building called the *Thermæ of Diana at Nismes*—a method probably employed in the first instance, as was suggested by a speaker in the discussion, to economise centering, the separate arches only being built on centering, and then forming the support to the intermediate portions of the vault. Miss Bell lectured, as usual, without any notes, carrying on her description and analysis of the building with perfect clearness and fluency, and showing a complete knowledge of architectural construction.

The Problem of By-law Relaxation.

LAST Thursday a standing committee of the House of Commons occupied the whole of the day's sitting in discussing a single clause of a Bill (promoted by Sir A. Griffith-Boscawen, and other Unionist members) to provide for the better application and enforcement of the Housing of the Working Classes Acts, and to amend the Small Dwellings Acquisition Act, 1899. The clause that took up so much time provided for the relaxation of the existing by-laws, and is the outcome of an agitation that has been gathering strength for many years: the argument being that over-stringency in by-laws, or their inelasticity of application, renders them actually inimical to the object they are intended to serve. That is to say, they often prevent the building of much-needed dwellings, especially in rural districts, by insisting on requirements that would raise the cost to a prohibitive figure and are at the same time obviously in excess of particular needs. The difficulty is that by-laws which are in certain circumstances necessary and appropriate enough cannot be relaxed where the conditions obviously render their enforcement unnecessary and even ridiculous. The clause in question provided for relaxation of the by-laws by a special department of the Local Government Board upon due cause being shown. A Government amendment to the clause would make it exclude all applications for relaxation except those promoted by the local authority. Sir R. Baker objected to this restriction, and moved an amendment to include schemes promoted by private individuals, co-operative societies, or public-utility associations. Mr. Burns opposed this amendment on the ground that "it would involve risks that housing reformers should not take"—the chief of such risks being, apparently, that of lowering the general standard by encouraging minimum observance. Mr. Burns bluntly said that in this matter private persons were not to be trusted, and that he had known co-operative and public-utility societies with whom charity covered a multitude of sins. "While anxious to give exemptions in proved cases, he declined to remove the protection the poorest now have under the existing by-laws of the good local authorities who were standing up against the jerry builder." At a later stage of the discussion, however, he said that he was prepared to consider definite schemes submitted by public-utility associations or individuals, and to give greater elasticity and wider exemptions than now prevailed, though he must decline to accept the amendment, upon which discussion had not been concluded when the committee adjourned

till June 6th. Apparently Mr. Burns is by no means opposed to the principle of relaxation, but probably he foresees a very formidable practical consequence of admitting all sorts and conditions of claimants for exemption. It would impose an intolerable burden on the Local Government Board, because everybody who desires to build meanly would try his luck as to exemption, and the Board would have no real means of determining whether or not any such demand was reasonable. The problem, indeed, is not an easy one to solve, since it must always be a delicate task to determine when a law or a by-law of beneficial intent can be beneficially relaxed; especially when, as in the present case, it is so much easier to generalise than to discriminate. Nevertheless, the Government is committed to the delicate task of devising some efficient means of distinguishing the cases to which certain prescriptive by-laws are and are not strictly applicable. Until this peculiarly sensitive machinery is set up, we shall, as Sir A. Griffith-Boscawen gracefully expressed it, "never get a move on in this matter of housing."

Pictures by Josef Israels.

AT the French Gallery in Pall Mall East there is on view a memorial exhibition of works by the late eminent Dutch painter, Josef Israels, who died last year at the age of eighty-four. Israels was no doubt in his way a great painter, from his broad style, his mastery of colour and texture, and the simple and direct manner in which he went to the heart of his subject, omitting everything except what was essential to it; one could fancy him echoing Millet's dictum, that every detail which does not assist the main subject of a picture is a positive injury to it. But he is an artist perhaps better appreciated when one sees one of his best works separately than when one studies a number of them collectively. His preference for melancholy and even sordid aspects of peasant life, and the almost entire absence of bright colour (except in some of his small outdoor scenes with children playing), renders a whole roomful of his pictures rather depressing to the spirits; we seem to see only the unhappy side of life portrayed in them. But he found in this class of subject the real outlet to his genius, and painted what he felt. One or two obviously early works without any of these melancholy characteristics are nevertheless of little value, except to show in how academical a manner he painted in the days before he had found where his real power lay.

Sta. Sophia, Constantinople.

THE news that Justinian's great church at Constantinople is in a dangerous condition is enough to send a thrill of anxiety through the whole architectural world—we might almost say, the whole educated world, lay and professional. Such seems to be the fact, however. We have even heard it authoritatively declared that without extensive reparation the great dome cannot be considered to have a more than twenty years' lease of life from the present moment. It appears that some two or three years ago a well-known French architect, M. Prost, assisted by an Italian architect, made an examination and report on the building by request of the Turkish Government, but both were so little pleased with the treatment their report received that they withdrew it and quitted the field. M. Prost, we remember, either last year or the year before, exhibited at the Salon a complete set of measured drawings of the building, showing, among other things, the serious cracks in at least one of the main piers supporting the dome. The question is, What is to be done? Sta. Sophia is such a wonderful building, so absolutely unique as an example of dome construction on a great scale, that its preservation is a matter of interest for the whole civilised world; and it is in very bad hands at present. It is perfectly certain that Turkey cannot

find much money to spend on the building, nor can the Turkish authorities, even if they had the money, be trusted to do the best for the building; there is evidently great reluctance to allow the unbeliever to have anything to do with it; and in that case it would probably be insecurely patched up by some Turkish architect whose engineering skill could not be depended on. If money is the principal obstacle, the Governments of the leading countries of the civilised world ought to combine to find the necessary funds. It is a matter of world-wide interest.

Proposed New Liverpool Custom-house.

WE do not quite understand the position in regard to the great excitement there seems to be in Liverpool about a scheme for a new custom-house. For some reason, the Government has proposed to grant a sum of £100,000 towards a new custom-house on condition that the Liverpool Corporation find £50,000 to add to it. On this basis, some of the Liverpool people seem to have been indulging in dreams of architectural magnificence, of a new and palatial custom-house with a grand river frontage; and considering the importance of Liverpool as a port it seems quite right that she should possess a palatial custom-house. But £150,000 will not go far towards producing such a building. And then we should like to hear what is to become of the old custom-house. Is it to be destroyed? In its plain and severe style it is a rather fine example of the old school of revived Classic architecture, and its dome has been a landmark from the Mersey for, probably, over a century. It has, therefore, a certain historic as well as architectural interest, and we should be sorry to hear of its demolition, which would, we suppose, be the natural consequence of the new scheme, though nothing seems to have been said about this so far. But it is quite certain, at all events, that if the ambitious architectural ideas about the proposed new custom-house are to be realised, a good deal more money will have to be forthcoming than has yet been talked of. It is no use trying to do architectural magnificence by halves.

The London University Site.

THE idea of purchasing the Foundling Hospital estate as a site for the London University, which was suggested in a letter in the "Times" of the 17th, seems worth consideration. It is true that the old Hospital is an institution of some historic interest, and there would be many who would naturally regret its demolition; but, on the other hand, there is the consideration that the children would be in a much better situation for their health if the Hospital were removed into the country. At the time the Hospital was founded its site was practically in the country, at all events it looked upon open fields to the north; we find in one of Jane Austen's novels a reference to the salubrity of Brunswick Square as being "so very airy." Now there are close-packed houses all round it, and the situation is quite altered; it is the case of Christ's Hospital school over again. In regard to extent and central position the site seems almost all that could be desired for the University.

Presentation to Mr. George Macfarlane.

OF few men could it be said, as was said on Thursday last of Mr. George Macfarlane, J.P., of Manchester, that he had received "all the honours, both local and national, which the building trade could confer upon him." But those who have known Mr. Macfarlane will agree that the honour thus bestowed is full well placed. Mr. Macfarlane has indeed done great service to the building trade during the period of more than forty years he has been connected with it. By his election to numerous offices this has already been recognised, but as a personal token of esteem a gift of a cabinet of cutlery, a silver tea service and tray, silver fruit dishes, and an illuminated

testimonial was made to him last week by Mr. Henry Matthews on behalf of the Manchester, Salford, and District Building Trades Association, and from friends engaged in the building trade throughout the country who had desired to contribute. Mr. Macfarlane has been called "The Grand Old Man of the Building Trade," and he has filled with dignity and distinction the presidential chairs of the Manchester and Salford Master Builders' Association, the Lancashire, Cheshire, and North Wales Federation, the Northern Centre, and the National Federation of Building Trades Employers of Great Britain and Ireland. To all these affiliated organisations his wisdom, courage, and eloquence have been of inestimable service; and while he has been always distinguished for doughtiness in debate, wherein he seldom fails "to remember his swashing blow," he is nevertheless held in high esteem for the genial and kindly disposition which is the real fountain of his always righteous indignation. There is, in fact, no man in the National Federation who is regarded with more affectionate respect than Mr. George Macfarlane, and the presentation to him is a spontaneous manifestation of strong personal regard, as well as of gratitude for long, strenuous, and self-sacrificing services in an excellent cause.

The Burlington Fine Arts Club.

THE exhibition of Italian sculpture at the Burlington Fine Arts Club is one of the most remarkable which the club has held. One exhibit alone would make the exhibition worth a visit, the low-relief bust called St. Cecilia, lent by the Earl of Wemyss, and executed in some kind of black stone. This, if we mistake not, was exhibited a good many years ago at one of the Burlington House Loan Exhibitions, when, at the instance of Lord Leighton, the experiment was tried of devoting the water-colour room to a collection of works of decorative and applied art; an experiment which we wish had been repeated since. This bas-relief, in a large circular medallion, has been attributed to Donatello, but it is not very like his work, and the compilers of the catalogue evidently do not support this ascription; they suggest Desiderio di Settignano as the possible author. But whoever executed the work, it is one which may vie with the finest productions of Greek art.

Among the many fine works exhibited is a cast from Donatello's bas-relief of the Crucifixion, the bronze of which is in the National Museum at Florence, a work of great dramatic power. There are a good many relief subjects of the Madonna and Child by various artists; one of the finest is a work by Rossellino, towards the end of the fifteenth century. The low-relief "Profile of a young man crowned with laurel," lent by Mr. Newall, is a remarkable work, attributed to the latter part of the fifteenth century, but to which no sculptor's name can be attached. The genius of Settignano is displayed in the beautiful and expressive bust of "A Princess of Urbino," lent by Lord Wemyss, a work of the greatest refinement and dignity. Among the Madonna subjects is a very fine one by a sculptor known as "The master of the marble Madonnas"; in this the head is brought out into high relief; the interest of this work is rather in the execution than the expression, for the head is secular rather than spiritual in character. Among other works arranged round the room may be mentioned a small but singularly graceful composition of the Virgin and Child by Luca della Robbia, and a small alto-relief group of the dying Antony and a nude Cleopatra, the figures almost in the round—Baccio Bandinelli is suggested as the possible author of this fine little group. Four glass cases are filled with small bronzes of great variety of subject, and many of them very fine. The impression given by the whole exhibition is that the Italian sculptors of the fifteenth century came very near to the standard of ancient Greek art, in their best work at all events.

FAME AND THE ARCHITECT.

BY DARCY BRADDELL.

THERE is a story told of the late Sir Edward Burne-Jones, that when he was at the very zenith of his fame he came across an old gentleman in Birmingham who had been his drawing master in very early days. "Why, if it isn't Ned Burne-Jones!" said the old man, and thereupon stopped and talked to the great "B.-J." At the end of their conversation the old gentleman blandly inquired "Are you still keeping your drawing up?" This story is probably quite untrue, but that is of no matter. The fact remains that Burne-Jones *was* a famous man during his lifetime, as well as after.

Now, supposing that, instead of expressing himself in paint, he had been drawn by his love of mediævalism and mysticism into the meshes of architecture, the whole point of the apocryphal little story would have fallen to the ground for the very simple reason that he could never have been a famous man. The modern architect is not famous if compared with the leading men of the sister arts of painting and sculpture of to-day.

Should anyone have doubts on this point, I ask him as a member of ordinary cultivated society to enter any drawing-room he pleases, and discover of the occupants thereof three architects practising to-day whose names are the household words that Mr. Sargent's, Mr. Frank Brangwyn's, and Mr. J. J. Shannon's are. I think it can be safely said that he would have a difficult task indeed.

As to the hopeless obscurity a young architect is compelled to live in, no matter how much really good work he may have carried out, one has only to consider the celebrity which two of his contemporary brother artists—Mr. Gerald Kelly and Mr. Glyn Philpot—have already attained to realise the futility of even discussing it.

In America this unbalanced state of affairs does not go on. One of the greatest surprises that anyone interested in modern architecture in this country can have is to talk to an American woman and discover how keenly interested she is in the architecture that is going on in her own country, and how extremely well known to her are the modern American architect's name and work. We have got to such a pitch of apathy in our own architecture nowadays that, were the whole of Regent Street pulled down from end to end and rebuilt in a single night by a second Inigo Jones, not a syllable of his name would ever be divulged to the general public in the Press the next morning. The particular firm of contractors employed, the innumerable statistics of the numbers of workmen engaged, the tons of steel and stone required, the acres of glass, and so forth—all these would be mentioned; but the architect's name? No! not a word. Has this deplorable state of affairs always gone on in the days of the past? Most certainly not. In 1792, when Robert Adam died, he was buried in Westminster Abbey, and his coffin was borne by eight peers of the realm. During his lifetime, not content with his huge practice, he must needs wade into building speculations and, indeed, get woefully out of his depth; but so great was the influence at his command that he actually succeeded in getting an Act of Parliament passed to enable him, without falling foul of the law, to raffle Adelphi Terrace (the speculation in question) at £50 a ticket!

To turn to earlier times still; Christopher Wren and Inigo Jones were both infinitely better known than either Peter Lely or Kneller, and it is sincerely to be hoped they will always remain so. Most of us have heard of Vanbrugh, and not a few of George Dance, William Chambers, Kent, Soane, Nash, and, later still, Pugin. All these men had their fair share of fame, and were looked upon by society as great artists.

"All this is very fine and true," says the gentle reader, "but these men you have mentioned all deserved their fame; they were exceptionally brilliant men. Modern architects are not; they are very dull ordinary folk. As

for being artists, what have they got to do with art? Why on earth should they be famous?"

I suppose that the modern architect refuses to believe that this is the opinion of society. Perhaps, then, the next time he dines among the philistines (I refer to barristers, doctors, merchants, and such-like), when he propounds his theory that modern architecture is an art and should be looked upon as such, he will explain why his remark has been treated with the pitying smile that usually follows it. Perhaps he will go even further, and explain why the term "artist" is never applied to him, however important and superb a building he may have just erected, while any incompetent dauber assumes by his or her natural right that title.

As this is an age of science and mechanics, and probably at no time in the history of the world has thought become so shallow and slovenly as it is to-day, the art of this and other countries must suffer. The easy transmission and exchange of other people's ideas, the flooding on the market of cheap and, consequently, valueless information, have all done their deadly work, and the real thinker among the art patrons of to-day is as rare as the dodo. The result is that art has taken a back seat, no matter what the present-day artists like to think to the contrary. The peerage of England no longer takes a pride in discovering and making an artist, whether he is architect, painter, or sculptor. Turn a moment to the history of England, and you will read of Inigo Jones that "he attracted, by his skill in drawing, the attention of a nobleman, who sent him to Italy to study the art of architecture and landscape painting." Of William Kent, that "he was taken up and made much of by Lord Burlington"; of Nash, who built Regent Street, that "he was the favourite architect of George IV." You read of how, in the eighteenth century, all the peerage of England regularly made the "grand tour," and visited Italy, where they studied architecture, so that they might have the knowledge to choose the very best talent to build that noble series of palaces which stands to-day a memorial of the splendours and glories of the eighteenth century.

Alas! The Burlingtons, the Ilchesters, and the rest, are dead and gone. Their descendants have departed, most of them, into the City, where they direct companies; or into the garage, where they perform a like office to motor-cars.

This age of democracy has seen the rise of County Council schools, polytechnics, and innumerable provincial art schools. They all have scholarships for their promising students. The result has been, of course, that the art patron of the present day no longer feels it incumbent upon him to secure some knowledge of the art of his own time so as to be able to encourage it personally and in the proper direction. That, he argues, is the business of the National Art Schools, with their scholarships and travelling studentships. The patron consequently lives his life in a state of abysmal ignorance and apathy. There are some, it is true, who, deeply versed in the defunct art, are ardent devotees at the shrine of "Christie's." There they vie with the dealers for what their prototypes of past ages had the temerity and sagacity to commission for themselves from the artists and craftsmen of their day.

It may be argued that America is a flourishing democracy and yet has arrived at an architecture that is far in advance of ours in England. But, it must be remembered, America is a polyglot country, with no architectural past worth considering. The American millionaire, standing to his country to-day as the peerage of England stood to theirs in the seventeenth and eighteenth centuries, in that he is the man with the money-bags, realises this, and has commissioned his architects, with whose work he, or rather his wife, is thoroughly acquainted (just as society in England is acquainted with the work of Mr. Sargent and Mr. J. J. Shannon), to build for him on modern and palatial lines.

THE NEW HOUSES OF PARLIAMENT, STOCKHOLM. A. JOHANSSON, ARCHITECT.

He has no fear of spending money; he allows his architect very much more scope than we ever give him here. It is true that when his palace is finished he proceeds to fill it with the bones of dead and gone ages of Europe. Pictures and statuary, unfortunately for modern American painters and sculptors, are not difficult objects to convey across the Atlantic. A house, on the other hand, in spite of Tattershall Castle, is practically beyond this pale.

Millionaires are not wholly idigenous to the Western world; we have them here. But it must not be forgotten that we have an impoverished peerage and a large number of magnificent old houses. It is this fact that makes the great difference in architecture between ourselves and our American cousins. For our self-made plutocracy, instead of having the artistic courage to build large new houses of their own, are tumbling over one another to secure the fine old mansions of the impoverished peers, just as they also prefer to give fancy prices for antique furniture, silver, tapestries, and so forth, instead of commissioning the countless capable men of their own times to design fresh things for them.

It is to this lack-lustre patronage, this blind and, in many cases, absolutely ignorant worship of the antique that we must ascribe the decay of modern art.

The patron, wholly unversed in good taste, because the art schools have taken his proper patronage out of his hands, is now terrified of the blunder of not "getting his money back," and goes about in his complacent way saying "What awful stuff modern art is!" If anyone has the pluck to stand up and tell him he does not know what he is talking about, what coals of fire he will pour out on his unfortunate victim's head!

Very well, then, let us admit that owing to the various reasons that have just been discussed, architects to-day are not the equals of their departed brethren who practised in the seventeenth and eighteenth centuries, and let us agree that they do not deserve the fame those men attained. It does not alter the question, however, "Why should architects be less famous than sculptors and painters?" and "Why should the title 'artist' be solely applied to painters?"

It would not be difficult to contend that the architecture of to-day, although it has sunk from the high level it reached during the eighteenth century, is every whit as good as the painting and sculpture that are being carried out at the moment.

The answer to the two questions is quite a simple one. Architecture is the most scholarly and erudite of all the arts; it is consequently extremely difficult for the uneducated mind to comprehend its beauties and its failures alike. "A little knowledge is a dangerous thing." With the exception of admirable if desultory efforts made by the "Times" and, I think, the "Evening Standard," but leading to nothing, as far as the rest of the Press were concerned, no attempt has been made at critical notices of modern architecture by any popular journal, illustrated or otherwise, that is not solely devoted to art topics. Consequently, the unhappy public are compelled to do what they hate more than anything else—make up their minds for themselves. It is much easier to state without making a fool of oneself where any work of art does not please than it is to say where it does please. Therefore, the man in the street always condemns any new building because he likes best the line of least resistance. The state of affairs where a daily Press will give half a column to a trifling exhibition of water-colour sketches which are only going to be on show for three weeks at a Bond Street gallery, and not a single line of genuine or able criticism to an enormous building which has just altered the entire aspect of a main street of London, is one for angels to weep over.

It is high time for the Press to mend its ways and attempt to educate a public that at the present moment has neither the capacity nor the inclination into some reasonable appreciation of the architecture of their own times. They might not make a bad start by mentioning the architect's name when they turn out these wonderful reports of the laying of foundation stones by Royal personages.

I am perfectly aware that it does not really matter to a man whether he has recognition in his lifetime or not, but it is a very serious position for any art to find itself, as the art of modern architecture is finding itself to-day, where everyone practising it is refused anything like a really fair meed of recognition among a public who, after all, are its direct patrons. And as no rational interest in architecture is being taken by the Press, the schoolmasters of the public, not only are architects compelled to live in obscurity, but—far more important—so is the art of architecture.

A final word as to the abuse of the word "artist." I have tried to discover when this word first assumed its present

meaning: certainly not in the eighteenth century. Adam and Reynolds always referred to themselves as "architect" and "portrait painter." I believe I am right in saying that in no other country in the world does it solely apply to the painter's craft, as it does here.

Let the Press cease from indiscriminately labelling all painters as "artists." The word can be very easily left for the memorial tablet, the tombstone, and the statue. Better still, let the painters think twice of their last efforts before they unblushingly arrogate this title to themselves.

THE NEW HOUSES OF PARLIAMENT, STOCKHOLM.

THE design of so large a building as a new Parliament House generally affords plenty of scope for talent, and this was so in the case of the new Houses of Parliament at Stockholm. There are few more picturesque cities in Europe than the capital of Sweden, with its varied contour and its abundance of water; but these favourable natural conditions have not always been exploited or considered in the happiest manner in the placing and designing of new buildings. Opinions were very much divided when the Helgeandsholmen, a small islet, was finally selected as the site of the new Houses of Parliament, and the choice gave rise to a heated and protracted discussion. The Stockholmers were afraid that the new Houses would detract from the grandeur and dignity of the castle opposite; and, worse still, would interfere with the freedom of the view up and down the stream in the midst of which it now rises. On the other hand, one cannot wonder at the legislators giving preference to this position, which, from their point of view, is perfect. Mr. Aron Johansson, the architect, had a difficult task set him. The foundation-stone was laid with much solemnity on May 13th, 1897, and the building was ready for the 1905 Riksdag on its assembling in January. At the back the building has, by means of arches, been connected with the new building of the National Bank of Sweden, the two buildings supplementing each other architecturally so as to constitute an excellent whole. The material used for the outer surface is granite, which imbues the structure with a restful strength, and lends itself equally well to the mural motifs of decoration and to the large coats-of-arms over the main entrance, as well as to the four large figures representing the four classes or

"Stander" of the kingdom, and the still larger figure of Svea (Sweden) which crowns the central portion. Columns and pilasters have been used with considerable effect; though exception might perhaps be taken to the grooving between the stone blocks of the ground storey being somewhat exaggerated—a defect often noticeable in Germany, the town hall of Hamburg being a flagrant example. The illustrations are, however, sufficiently clear to make any detailed description unnecessary.

The interior may, in a way, be said to form a contrast to the outer treatment of the building, inasmuch as plaster and paint have been resorted to in lieu of marble or stone. Light colours predominate on the ground staircase and in most of the rooms and corridors, and the impression received is perhaps not quite what one expects in the palace of a country's legislature. The arrangements, however, are practical throughout, and many details have been most carefully considered. The halls for the two chambers are octagonal, panelled (with beech wood), and awaiting some final artistic decoration. Both these halls have top lights.

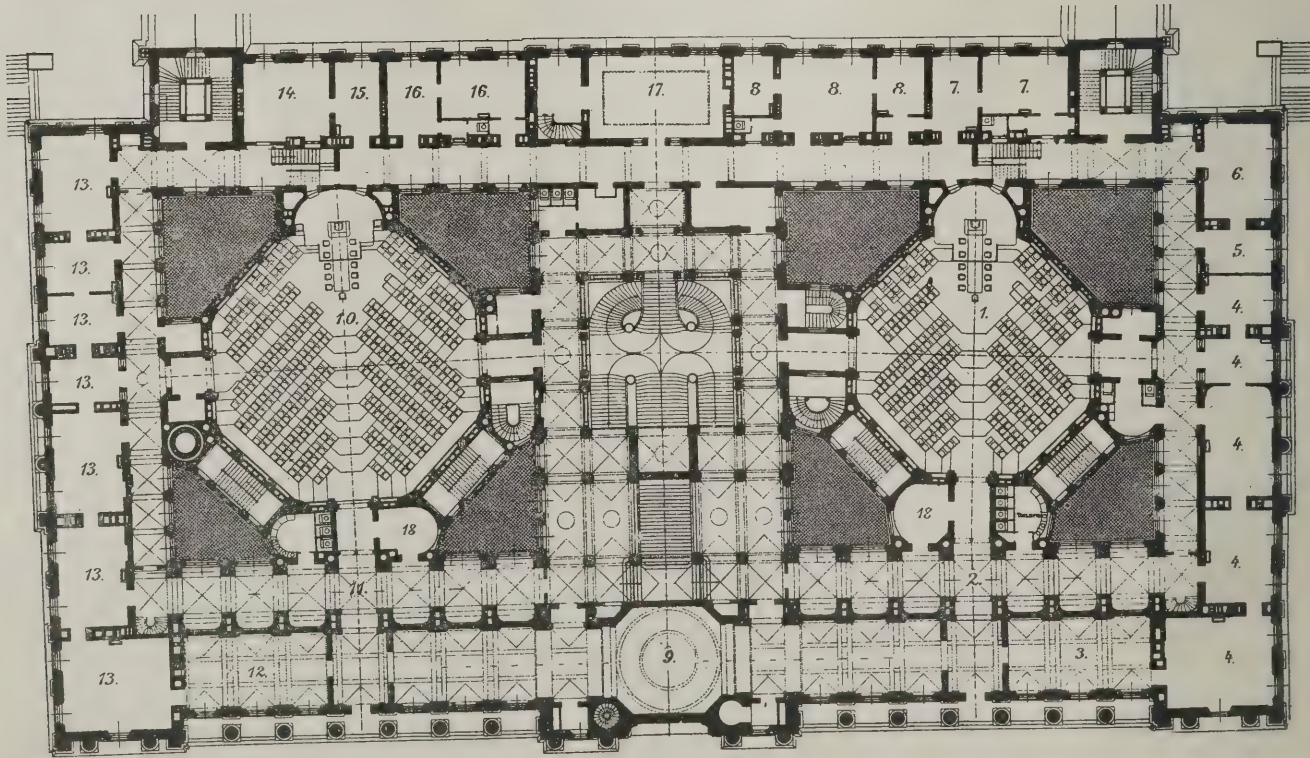

The dimensions of the building are—length 350 feet, width 190 feet, and height from pavement to top of roof 72 feet.

CORRESPONDENCE.

The Editors disclaim all responsibility for the statements made or opinions expressed by correspondents. Correspondents are asked to be brief, and to write on one side only of the paper.

The R.I.B.A. Elections.
To the Editor of the ARCHITECTS' AND BUILDERS' JOURNAL.

SIR,—The Institute Members' Club have issued a circular to members of the Institute exhorting them to vote only for those candidates for the Council who will be active in promoting "a strong and vigorous policy" in favour of the immediate preparation of a Registration Bill, and giving a list of the candidates who can be counted on for such action.

As one who considers Registration to be a farce, I feel much indebted to the Club for furnishing me with this list, and will take care to strike out all those names in my voting paper; and I hope those who think with me will do the same.

A FELLOW OF THE INSTITUTE.

To the Editor of THE ARCHITECTS' AND BUILDERS' JOURNAL.

SIR,—Regularly with the advent of the R.I.B.A. Council and Committees elections each year there appear in the columns of the professional Press pathetic letters from gentlemen asking for instruction and help in filling up their voting papers. Such an one has appeared within the last fortnight, reiterating the same old complaint in the following terms:

"The time will soon arrive again when the members of the Institute will have to elect their representatives on the Council and various Committees for the coming year, and bearing in mind the difficulty the average member has in deciding for whom to vote, I venture to inquire if something cannot be done to assist him in his selection.

"I think I am safe in saying that to most members many of the candidates—particularly new ones—are comparatively, if not quite, unknown, or if known, their ability, work, and experience are not. It must be remembered that the architect gains his knowledge of his professional fellows chiefly by means of the building journals and the various particulars of buildings they publish. Now there are many men of large practice whose names never seem to get into print, and whose drawings are never published; it follows then that these men are probably unknown to their brother architects, and when, as sometimes happens, they are listed among the candidates, they invariably fail to receive sufficient support for election, notwithstanding that their experience is far greater than [that of] many of those who do manage to gain a seat."

... I think that many, both on the Council and off, must agree with the entire truthfulness of the statement above quoted, and I am convinced it is a matter which should be inquired into with a view to adopting some procedure to more satisfactorily meet the needs of these progressive days.

I believe there exists an almost unanimous feeling against individual canvassing in a body such as ours, but this does not prove the case *pro* or *contra*. In the case of Parliamentary candidates, and I believe I am right in saying in other of the professions (closed and otherwise), canvassing is adopted as a matter of course, without where everyone is on the same footing) any great harm ensuing. Personally speaking, I can see very little difference

between canvassing openly and canvassing by such means as writing letters to the professional Press just previous to the elections by gentlemen who are candidates for the same. The professional Press of the last few weeks provides some delightful instances of what can be done in this way.

The writer of this letter is also a candidate, but in his case he desires to carefully retain his anonymity, and therefore signs himself

MEMBER, R.I.B.A.

To the Editor of THE ARCHITECTS' AND BUILDERS' JOURNAL.

SIR,—Re paragraph p. 516 in your issue May 15th, entitled "To R.I.B.A. Associates," as the seconder of Mr. Bonner's motion on March 4th it is satisfactory to me to see that apparently action is being taken in the matter of increased representation of Associates on the Council; but whilst welcoming any procedure which can help the Council to a just conclusion (and incidentally add to the Institute coffers), I fail to see of what service the information they seek can possibly be, in that the mere sending in of such information is by no means the whole of the liability, as, apart from anything of the kind, before any Council could formulate

a statement for or against, it would be necessary for each correspondent to complete the matter by sending photographs, working drawings, statements of his own and his proposers, as to his professional education, etc.

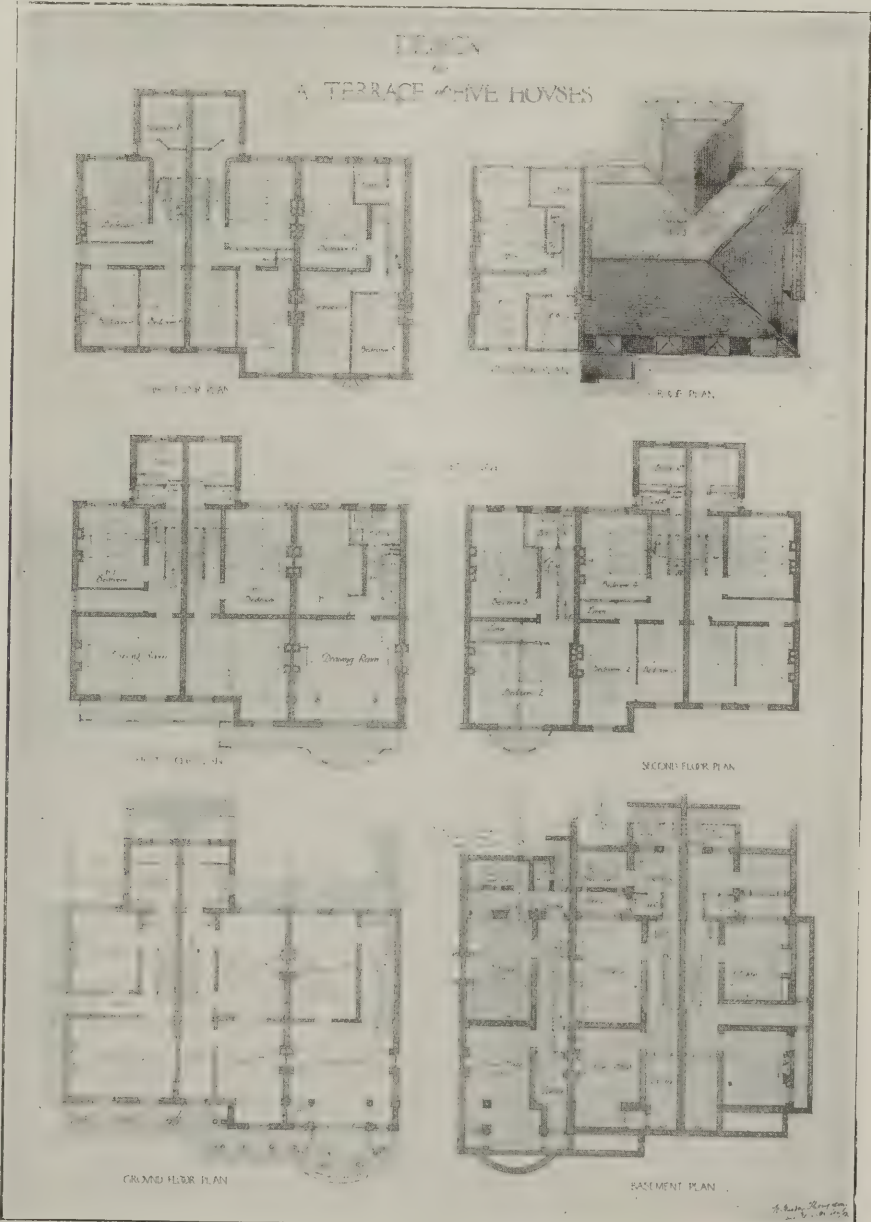

Granted this, that might not be the finish, for I venture to anticipate that should the Associates as a class conceive the idea that to meet their just demands for increased representation the Council were "going out of their way" to, figuratively speaking, "rope in" half-hearted members, there might be seen a similar state of things to that which obtained about five years ago.

As one who has fought from the very first for fair dealing for the Associates, I venture to suggest that two classes having been set up within the Institute, representation equitable to both should speedily be arrived at for the well-being of the Institute.

THE SECONDER OF MR. BONNER'S MOTION, MARCH 4TH.

OUR PLATE.

Design for a Terrace of Seaside Houses.
The design by Mr. W. Harding Thompson for a terrace of five houses in a seaside

BY W. HARDING THOMPSON.

town, reproduced as the centre plate in this issue, is not only interesting in itself, but more particularly for the reason that it is one of two sets now being circulated among the Allied Societies as examples of the kind of draughtsmanship desired for the new Problems in Design which are to take the place of the Testimonies of Study for the Final Examination of the Royal Institute of British Architects. The subject of the design in question was one of two under Subject I., the other being a monument to King Alfred, Mr. H. Chalton Bradshaw's design for which was reproduced in our issue for May 8th. Both Mr. Thompson and Mr. Bradshaw, it may be mentioned, are students at the School of Architecture, Liverpool University.

The third subject set comprises (1) a detached ball-room to a large country house, and (2) a landing stage to a river or lake, with a restaurant, the drawings for which have to be sent in to the Board of Architectural Education by June 30th next.

COMPETITIONS.

Hale Town-Planning Competition.

With respect to this competition, Mr. Arthur S. Brewis, Secretary of the Manchester Society of Architects, has addressed the following circular, dated May 16th, to the members of his Association:—"Dear Sir,—Since sending you the notice dated 29th ult., my Council are glad to say that the District Council have reconsidered their decision, and have agreed to revise the conditions in respect to the three points named, viz.: To issue a plan of the district

for the competitors, with particulars, up-to-date, of houses, sewers, and main levels. To delete the clause in their conditions asking for the architect's inclusive fee for subsequent work. To appoint a competent advisor, to be approved by the Council of the Manchester Society of Architects, to assist the Committee. An extension of time for sending in plans will be given. My Council instruct me to inform you that these conditions as revised are satisfactory. My notice of the 29th ult. is therefore withdrawn.—Yours faithfully, ARTHUR S. BREWIS, Secretary."

Elementary School, Knavesmire.

Twenty-nine of the 203 designs submitted in this competition are on view (May 17th to May 31st) in the South Galleries of the Exhibition Building, York. The assessors, Messrs. T. Mellard Reade and Son, awarded the first premium to Mr. J. T. Proffitt, of Walkden.

New School, Greenock.

The Greenock School Board last week appointed Mr. William R. Glen, Glasgow, architect for the new school which is to be erected in the West end of the town. Mr. Peter Caldwell, Paisley, was placed second (premium, 40 guineas) and Mr. James Rome, Kilmarnock, third (premium, 30 guineas).

Competition for National Welsh Sanatoria.

The Executive Committee of the King Edward Welsh National Memorial for the Prevention and Abolition of Tuberculosis

met on Thursday last at Westminster, when it was reported that the total promises and donations amounted to £201,740. It was decided to advertise for suitable architects, with a view to the erection of sanatoria, and Sub-Committees were appointed to go into the question of sites.

LONDON MASTER BUILDERS' ASSOCIATION.

The Council of the London Master Builders' Association met on May 9th, when there was a particularly large and influential attendance. The chair was occupied by the President (Mr. James S. Holliday).

The Special Committee which was appointed to confer with the representatives of the carpenters and joiners *re* working rule agreement submitted its report of the conference held on the 1st instant, which was unanimously adopted.

The operation of the National Insurance Act (1911) was considered, and the Council decided to formulate instructions to be sent to the members of this Association for their guidance in carrying out the requirements of the Act.

Various correspondence was read relating to trade matters, including the Railways Bill.

The following were elected members of the Association:—Ordinary members: Messrs. H. J. Carter, Ltd., London and Grays, Essex; Messrs. Bovis, Ltd., Upper Berkeley Street, W. Associate member: Mr. J. B. Smith, 117, Hampstead Road, N.W.

EPSOM PARISH CHURCH. NICHOLSON AND CORLETTE, FF.R.I.B.A., ARCHITECTS.

Photo: Cyril Ellis.

EPSOM PARISH CHURCH.

The walls of this church are rubble built in mortar, with brick bonding courses at intervals, and about 3 ft. in average thickness. The piers are of ashlar masonry, and carry a system of alternating barrel and intersecting vaults. The bays are divided by broad transverse arches carrying the vault webs and also thin brick partition walls, which serve instead of wooden roof trusses. The long purlins from wall to wall are braced and strutted longitudinally, and a light roof of spars, boarded and slated, is laid on these.

The barrel vaults are of concrete with slight reinforcement. The groined bays are filled in with chalk, and the ribs are all of wrought stone. The external flats over the organ loft and aisle bays are of Kleine brick construction.

The thrusts in this building are dealt with by providing buttresses partly internal and partly external, as will be seen from the plan. But in joining the west end of the new church to the east end of the old one, which is to be pulled down when the permanent west end is built, it was not possible to provide buttresses of the proportions adopted for the permanent structure. The angles of the bay of groining at the west end of the portion of the new church first built were therefore strengthened with diagonal steel rods embedded in a cement-concrete filling at the back of the vault web. The result has been satisfactory so far, as no indications of any movement have been detected. But the whole stability of the structure will be increased when the western bays can be completed.

In a church of this design it would appear that the thrusts are largely neutralised by the interposition of barrel vaults between the groining bays. The lighting of such a building is also satisfactory, as the windows can be kept up and a considerable effect of internal space can be obtained with moderate dimensions. Messrs. Nicholson and Corlette, F.F.R.I.B.A., were the architects, and the builders were Messrs. Benfield and Loxley, of Oxford.

THE LONDON COUNTY HALL.

Premature Complaints of Delay.

At last week's meeting of the London County Council complaints were made of the rate of progress in the building of the new County Hall, and the Finance Committee was instructed to consider how the work can be expedited.

The subject arose on the Establishment Committee's vote of £72,150, which formed part of the annual estimates of the Council. Mr. J. D. Gilbert said the work was proceeding very slowly. As far as the man in the street could judge, the raft and part of the foundations were all that appeared to have been built up to the present, and the work would not be finished until 1916, which time was longer than any private firm would allow. Mr. Edward Smith said that when a deputation visited the site during the preceding week only sixty-two persons were at work there. At the present time for its various offices in thirty-seven different centres the Council was paying £1,000 a week in rent, and at the present rate of progress they would not be in the new hall by 1926. Mr. F. L. Dove declared that the contractors were well ahead of their time, and that the drawings for the superstructure had not yet been passed. He believed that the building could be finished before 1916 by

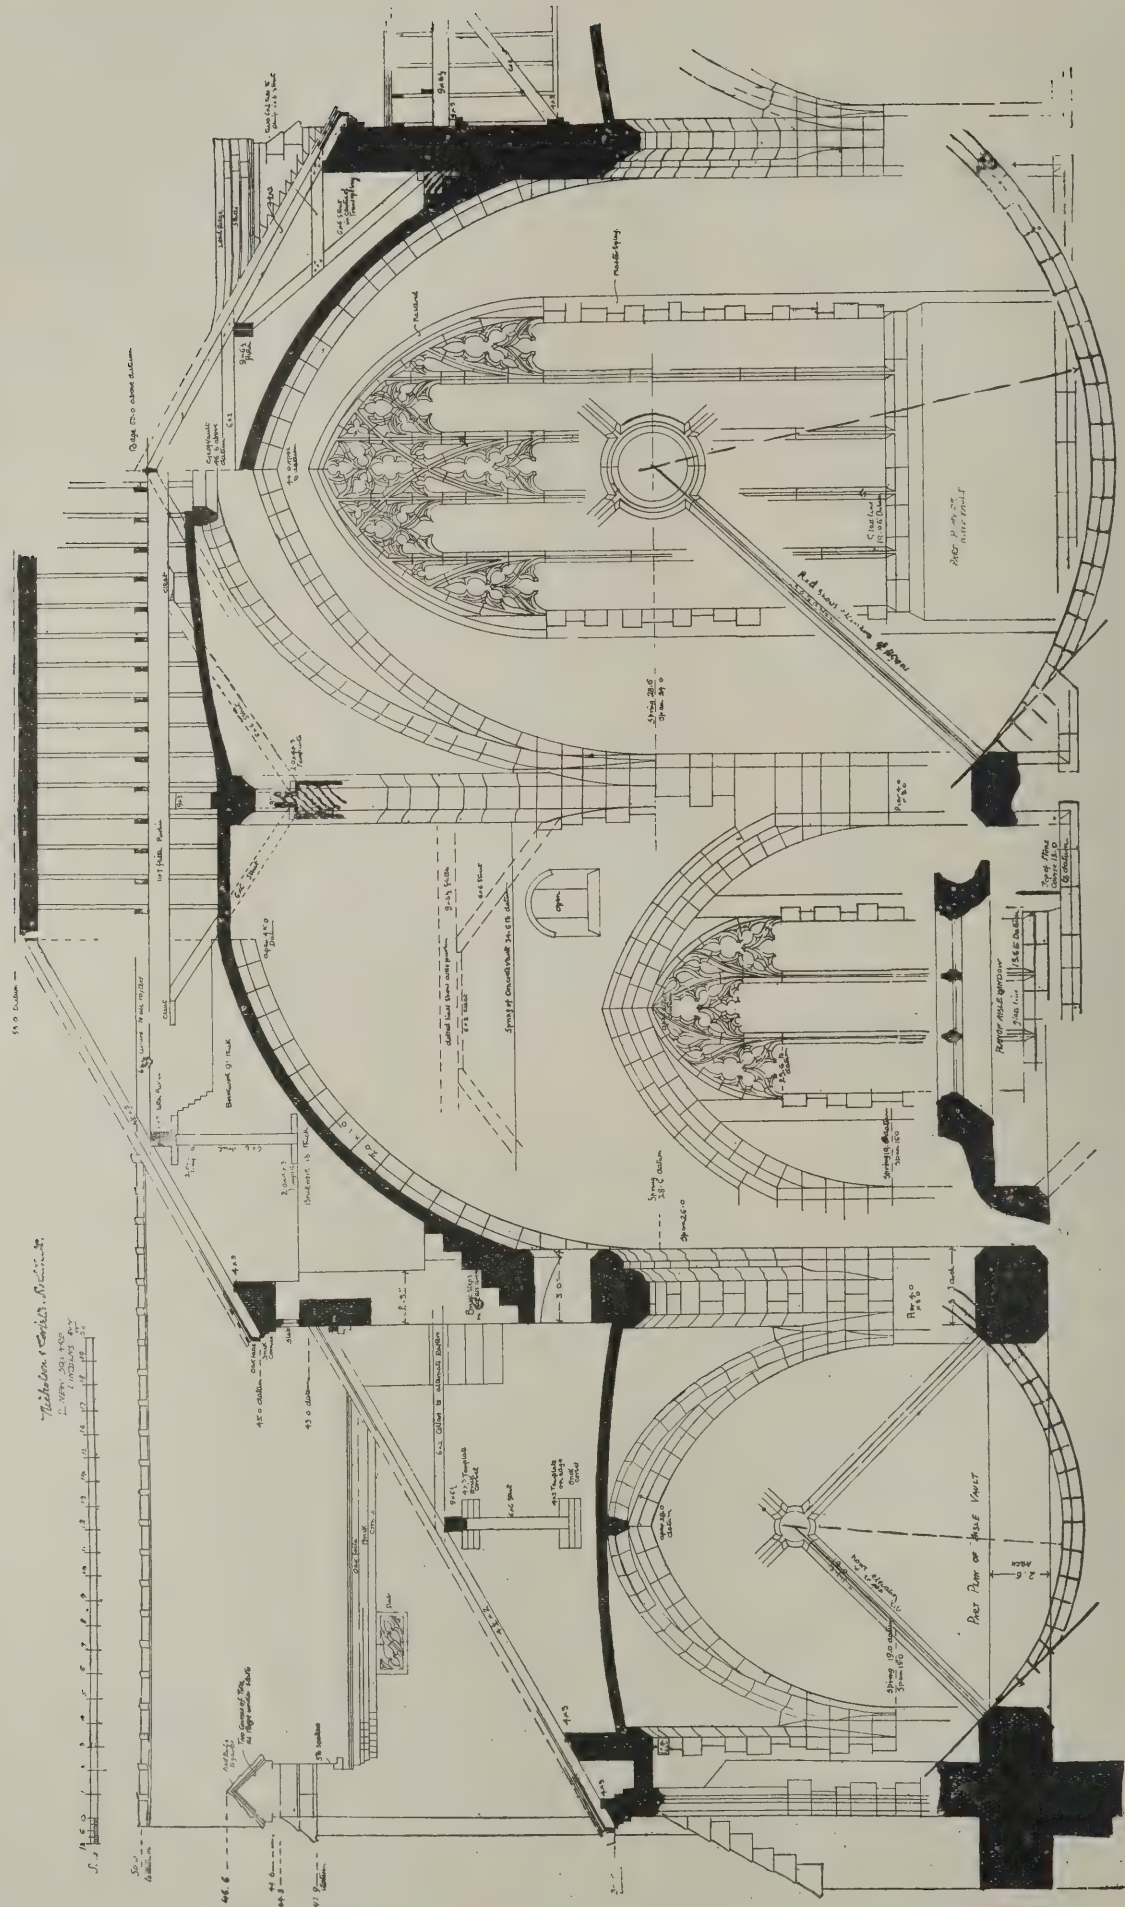

EPSOM PARISH CHURCH. NICHOLSON AND CORLETTE, F.F.R.I.B.A., ARCHITECTS.

offering a premium for earlier completion when the contract for the superstructure was issued.

Sir E. White said that on visiting the site he was told that there were sixteen bricklayers employed. As a matter of fact there was room for 300 bricklayers for months to come. There ought to be 600 men at work on the site, which was singularly well favoured. The trouble was due to the fact that all the plans and details had to be approved by two architects. They would be lucky if they got the building finished in seven years. The present delay would go on unless some drastic

measures were adopted. Mr. I. Salmon, chairman of the Establishment Committee, stated that it was unfair now to raise the question of delay, as in 1907 they were told that the building could not be finished before 1918. In fifteen months' time the whole substructure would be finished, and they would then be able to start on the superstructure, which would probably take three years to build.

Mr. Evan Spicer moved an amendment instructing the Establishment Committee to consider how the work could be expedited, and this was unanimously agreed to.

EPSOM PARISH CHURCH: DETAILS, NICHOLSON AND CORLETTE, F.F.R.I.B.A., ARCHITECTS.

NEWS ITEMS.

Charter for Irish Antiquaries.

A charter has been granted, under the Great Seal of Ireland, to the Royal Society of Antiquaries of Ireland, of which Count Plunkett, H.A.R.I.B.A., is president.

Mr. Benjamin Morton.

The death is announced of Mr. Benjamin Morton, Bakewell, who for many years carried on an extensive business as a builder and contractor in Manchester and elsewhere. Mr. Morton was seventy-two.

The Auctioneers' Institute.

Mr. Arthur William Brackett has been elected to succeed Mr. John Marks as President of the Auctioneers' and Estate Agents' Institute. Mr. Brackett, who was elected a Fellow of the Surveyors' Institution in 1886 and of the Auctioneers' Institute in 1894, was President of the Estate Agents' Institute in 1906-7.

Surveyors' Visit to Nottingham.

It has been decided to hold the next country meeting of the Surveyors' Institution at Nottingham on May 30th and 31st. Visits will be paid to various factories and to the Derwent Valley Waterworks, while there will also be an excursion to "The Dukeries," members driving through Thoresby and Clumber to Welbeck.

Decoration of St. Peter's.

Next month the work of covering seventy-six pilasters in the interior of St. Peter's, Rome, with white marble will begin. This gigantic task, for which an international subscription has been opened, is estimated to cost £1,400 per pilaster, or £106,400 in all. The Pope is taking great interest in this long-projected completion of the internal decoration of St. Peter's.

Advertisements on Bridges.

At last week's meeting of the London County Council a recommendation to the effect that the South-Eastern Railway Company be granted permission to place an advertisement of certain ales and stout on the bridge carrying the railway lines over Southwark Bridge Road was referred back. The vote followed a discussion in the course of which Mr. Pilditch asked the Council to imagine the effect on the Embankment if these advertisements were to be allowed on all bridges.

Liverpool Cathedral.

Sir William Forwood, on behalf of the Liverpool Cathedral Committee, announces that it is their ambition to complete the first part of the cathedral within the next four years. During the past ten years the Committee have collected £327,827, and have had special offerings for fittings, furnishing, etc., valued at £75,355. The completion of the lady chapel, choir, vestries, and chapter house will exhaust the funds. The cost of the nearest choir transepts will be £74,000, and to enable them to be consecrated with the choir the money must be obtained before the close of this year.

The Two New London Bridges.

At a dinner given by him at the Savoy Hotel last week, the Chairman of the Bridge House Estates Committee of the City Corporation, Mr. J. W. Domoney, said that now that the Act was passed the improvement of Southwark Bridge would be begun almost immediately. The tenders

would be considered within the next few months, and he estimated that the improvement of the bridge would be completed within two years and a half. The Committee would be able to start St. Paul's Bridge practically as soon as Southwark Bridge was completed, and meanwhile arrangements would be made for the approaches to that structure. With

Mr. Basil Mott, the engineer responsible for the improvement of Southwark Bridge, would be associated Sir Ernest George, A.R.A., in the capacity of consulting architect. Mr. Mott would also be the engineer for St. Paul's Bridge, and an eminent architect, whose name he could not yet announce, had been approached with a view to assistance.

DETAIL OF STAIRCASE AT REDLAND COURT, BRISTOL. JOHN STRAHAN, ARCHITECT.

MANCHESTER'S OLD TOWN
HALL.

Difficulties about its Re-erection.

The opposition of people in the Rusholme district to the proposed re-erection of the façade of the old Manchester Town Hall in Platt Fields, on a site within the park opposite Norman Road, was again expressed at a conference held last week between the Parks Committee, the representatives of Rusholme Ward on the City Council, and Sir Edward Donner and Mr. William Royle, leading residents in the district. Mr. Alderman Harrop, chairman of the Committee, presided.

Mr. Alderman Ashton (chairman of the Birch Fields, Platt Fields, and Whitworth Park Sub-committee) said that if the Parks Committee adhered to their decision to re-erect the façade at the place indicated a public meeting of protest would be held against the scheme. Rusholme people would have nothing to do with it, and they suggested that Heaton Park would provide a much more suitable site.

Sir Edward Donner thought the structure would be an eyesore and a blot upon the landscape.

Mr. E. F. M. Susman, Mr. W. F. Lane-Scott, and Mr. J. D. Chantler (the councillors for the ward) appealed to the Committee to reconsider its decision, the last-named speaker describing the façade as a "gloomy monstrosity."

In the course of the discussion the City Architect (Mr. H. Price) said in reply to a question that the stonework could not be cleaned without spoiling it.

Mr. Edgar Wood (president of the Manchester Society of Architects) asked by the chairman to give the Conference the benefit of his views, denied that the Committee's scheme would in any way injure the park. He said that the structure itself was too fine a thing to spoil any park, and indeed he knew no park really worthy to receive it. He contended strongly that there was no force in the arguments of those who opposed the setting up of the façade at the entrance to the park, a site which he described as in every way appropriate.

Mr. Alderman Harrop assured the deputation that the Committee's only desire in the matter was to do the best for the citizens, and expressed regret that, seeing that there was such strong opposition, it had

not found vent before matters had reached their present stage.

Mr. Royle replied that as soon as information about the intentions of the Committee was available a public protest was made.

Mr. Alderman Harrop promised that the Committee would reconsider its decision and communicate the result to the members of the deputation.

The Committee later in the afternoon visited Heaton Park and Alexandra Park with the view of arriving at a possible solution of the difficulty.

DETAILS OLD AND NEW—XLI.

Staircase at Redland Court, Bristol.

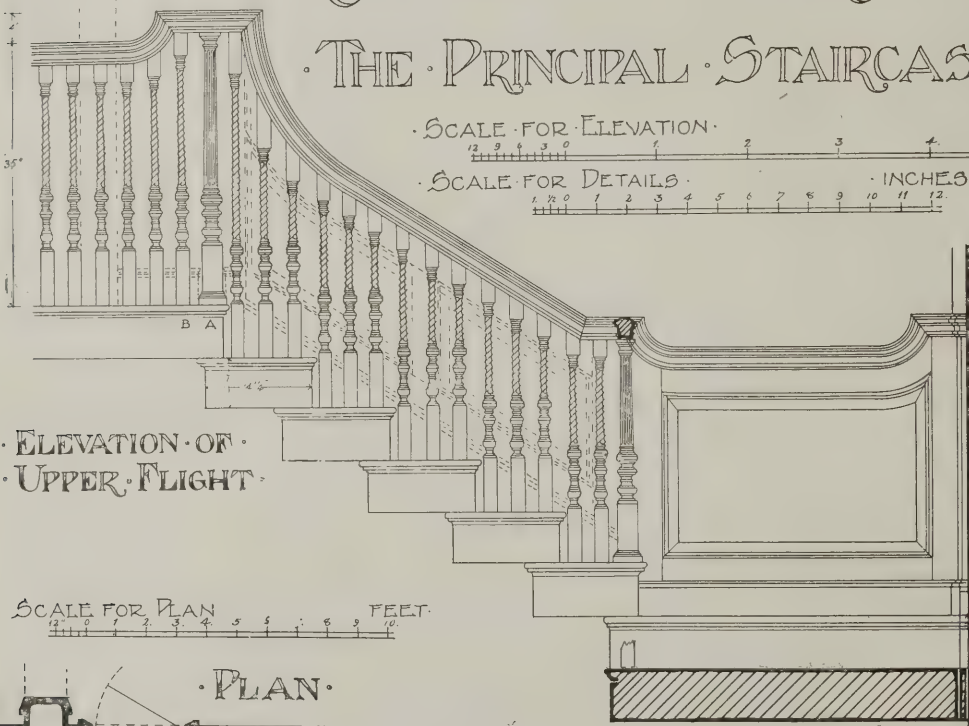

Redland Court was built in 1730 for John Cossins, Esq., a merchant of London. The architect was John Strahan. The house has been in the possession of several families, and is now used as a high school for girls. The staircase is of oak, the balusters being particularly well executed. The alcoves (dotted on plan) have been filled up.

CONCRETE AND STEEL SECTION.

(MONTHLY.)

*Concrete
Institute
Expansion.*

The proposal made last October that the scope of the Concrete Institute should be extended has received the approval of the Council, and a Committee of ten members of Council, under the chairmanship of Mr. E. Fiander Etchells, appointed to consider how the proposal could best be carried out, has issued its report, of which an abstract is appended to the Council's report for 1911-12. The Committee found that the rules of the Institute do not limit its scope to concrete and reinforced concrete, a clause in them enabling the Institute to deal with iron (including steel), bricks, gravel, sand, cements, and other structural materials, and their application. Hence it follows, apparently, that the inclusion of structural engineering is not *ultra vires*. For the purposes of the Institute, structural engineering is defined as "that branch of engineering which deals with the scientific design, the construction, and the erection of structures of all kinds in any material." As if realising that this basis could not well be broader, the Committee immediately define "structures" as "those constructions which are subject principally to the laws of statics, as opposed to those constructions which are subject principally to the laws of dynamics and kinematics, such as engines and machines." The Committee probably know best whether it was wise thus expressly to exclude the engines and machinery which are already, to some extent, and in the future may be more extensively, associated with construction; and, for example, one would like to know whether the definition would shut out from membership the makers of concrete-mixing, hoisting, and pile-driving machinery, and so forth. If engineers of this sort are ineligible for ordinary membership, perhaps they might be admitted as honorary members, since occasionally they might have much to learn and something to teach in the counsels of the Institute.

Other recommendations of the Committee are of subsidiary importance. The enlargement of the scope of the Institute naturally suggested a corresponding modification of the title. It was decided to retain the title, "The Concrete Institute," as it stands, and it was recommended that the development of interest should be signalled by adding to it the words, "An Institution for Structural Engineers, Architects, etc." The sub-title is not strikingly felicitous, either in its inception or in its wording. A sub-title of any kind is usually ineffectual; and in this case there is some suspicion of inconsistency in calling the same thing, in the same breath, an institute and an institution. The engineers seem to prefer "institution," whereas the architects may be supposed to entertain some prejudice in favour of "institute." The form derived directly from the Latin may be as euphonic and as scholarly as that which comes through the French; but although one is as good as the other, it is odd to employ both. Then why run the risk of exciting jealousy by giving precedence to structural engineers over architects? Alpha-

betically, at all events, there would have been sufficient excuse for inverting the order. As it is, the architect (who is peculiarly apt to be supersensitive) may resent the appearance of bringing up the rear. Rather than introduce a sub-title at all, it would perhaps have been better to alter the main title to read, "The Concrete and Steel Institute" (which, however, would almost infringe an existing title) or "The Concrete Construction Institute." These suggestions will perhaps be taken into consideration when the time comes for revising the rules (and perhaps the constitution) of the Institute; for it must be borne in mind that the suggestions of the Committee are at present merely tentative.

Further proposals of the Committee are that an annual course of technical lectures on some branch of structural engineering shall be instituted, and that examinations in the subject shall be held once a year, to test the scientific or technical attainments of applicants for studentship. Thus the Institute would become a teaching as well as an informally educative body, and would thereby enter upon a fresh phase of usefulness, and, while incurring further responsibilities, would set up a new title to respect, and establish a still stronger claim to support. The Institute, in fact, is discovering the lines of utility and interest along which it may develop successfully. By finding itself more technical and educational work to do, it will add greatly not only to the variety and interest of its proceedings, but to its dignity and influence as an institute or institution. If, in the process of development, it appears to cultivate the engineering at the expense of the architectural interest, that is probably the fault of the architect, whose fate with respect to reinforced-concrete construction is in his own hands. As one of many significant evidences of the Institute's ready recognition of the architectural interest, it is pleasant to note that, as the result of a ballot among members of the Council, it was decided to award a bronze medal for the best paper read in the past session to Professor Beresford Pite, F.R.I.B.A., for his striking if somewhat inconclusive essay on "The Æsthetic Treatment of Concrete."

BENDING MOMENTS AND FORMULÆ.

The paper on "The True Bending Moment of Beams with Various Degrees of Fixity," which was read before the Concrete Institute by Mr. Maurice Behar on April 11th, and part of which was published in our issue of April 24th, p. 435, called forth an extended reply from Mr. E. Fiander Etchells, F.Phys.Soc., etc., who, in moving the vote of thanks to the author, said that the adoption of reinforced-concrete work depended upon two factors, first its cost, and secondly its safety, and we should seek a reasonable compromise between these two divergent ideals—i.e., we wanted the greatest stability with the least cost.

He had heard the doctrine that rein-

forced concrete is subject to the laws of a super-statics of a recondite character, and that reinforced concrete construction is one of the occult sciences, whose laws transcend the laws of physics and of ordinary matter. But now that phase was passing away, even among the specialists themselves. The specialists had tried to lift reinforced concrete out of its cradle of empiricism and put it on a more settled basis.

The British specialists had recommended that in all important cases the bending moments under all possible conditions of loading should be accurately determined, and the beams be designed at each point in their length to resist the maximum bending moment which may occur at such point; but for small ordinary floors a sufficiently accurate result would be obtained by using a bending moment of $wl/12$, both over the support and in the centre of the span, for continuous beams.

The second report of the Joint Committee of the Royal Institute of British Architects recommended that the bending moments should be calculated on ordinary statical principles, and the beams or slabs designed and reinforced to resist these moments. Where the maximum bending moments in beams or floor slabs continuous over three or more equal spans, and under uniformly distributed loads, were not determined by exact calculation, the bending moments should not be taken less than $wl/12$ at the centre of the span and $wl/12$ at the intermediate supports.

This raised the question as to what the ordinary statical principles were. Would it be in accordance with the ordinary statical principles if, knowing that there is a bending moment of $wl/12$ at the support, we only provided for $wl/40$ or $wl/24$?

This report speaks of exact calculations, but the most exact calculations we have are based principally on Clapeyron's famous theorem of three moments, which was first published in "Comptes Rendus" about 1857. It is based on several assumptions, one of them being the constancy of the inertia moment. To solve the problem, it is necessary to employ the double integration of a differential equation; and though you work out the numerical result to the furthest decimal, what is the good of the result if there is a basic assumption that is far from the truth?

Speaking of steel-work, where there is admittedly a greater degree of continuity, in general it may be said that the bending moments at the supports next the end are always greatest, and are there about $wl/10$, and near the centre supports they are nearly uniform at about $wl/12$.

Since the draft regulations were written we have from America, the land of up-to-dateness, two further reports, or codes, and they both fully support the draft regulations in respect of the bending moments. The Joint Committee representing the American Society of Civil Engineers, and the principal scientific institutions over there, recommend "That for beams the bending moment at centre and at support for interior spans should be taken at $wl/12$, for both dead and live loads." Then, again, it goes on to say: "For spans of unusual length, more exact calculations should be made. Special consideration is also required in the case of concentrated loads. Even if the centre of the span is designed for a greater bending

moment than is called for by the previous paragraph, the negative moment at the support should not be taken at less than the values there given." Furthermore, it is stated that, "In the design of Tee beams acting as continuous beams, due consideration should be given to the compressive stresses at the support."

The New York Code, which came into force this year, states that "the bending moments at centre and support for beams or girders continuous over two or more supports shall be taken at $wl/12$." The Regulations of the Royal Prussian Ministry say that: "If conditions at support produce restraint and continuity of slabs and beams, the bending moments which appear at those points must have reinforcement placed near the upper stressed surface in proportion to the bearing area."

"If a continuous beam or slab cannot be computed, or, in regard to the latter, if no restraint is certain at a beam or wall, then, with equal panels and uniformly distributed load, the moment is not to be taken less than $wl/8$ over the supports, or than $wl/10$ at the centre of panels."

It has been said that the draft regulations under discussion would prohibit the use of reinforced concrete; that it would kill the trade. In reply, he asked whether the reinforced concrete trade was dead in Germany? Was it dead throughout the United States?

With regard to the breadth of Tee beams, we are also told that the regulations will militate against the use of reinforced concrete, but that does not seem probable when we bear in mind that the particular regulation referred to was suggested by the committee of specialists themselves. They unanimously and on their own initiative recommended that the width of the area under compression in Tee beams should not be greater than fifteen times the thickness of the slab or flange.

The New York Code revised this year states that the breadth of the compression flange of the Tee beam should not exceed twelve times the thickness of the slab plus the breadth of the rib. Therefore it would appear that the regulation under discussion of fifteen times the thickness, as recommended by the specialists themselves, is apparently good practice and also more or less accords with international practice.

Take the ratio of the breadth of the flange to the span of the beam, the regulations of the Royal Prussian Ministry say you shall only take one-sixth of the span as the breadth of the rib. The New York Revised Code gives the same figure. The American Joint Committee are a little more lenient; they say you may take one-fourth of the span.

The L.C.C. regulations allow twice the width of the Prussian, twice the width of the New York, and permit a breadth of one-third of the span. The complaints seemed to arise irrespective of the weight of evidence.

With regard to formulæ generally, it appears to me that formulæ represent the engineer's shorthand, and are a symbolic method of representing the truth; and so long as we do not mistake the symbol for the truth itself all will be well. Formulæ, after all, are merely epigrammatic methods of stating the laws of science.

It has been well said that "in physics the memory disburdens itself of its cumbersome catalogue of particulars and carries centuries of observation in a single formula."

The regulations are given in words or in formulæ, whichever are the most convenient.

Equations are vitally necessary, and they are necessary to ensure that the stresses are within the limits set by the regulations. Everyone has known that many times people have made the assertion that the stresses were under 600 lbs. per square inch after having made their own assumption about the bending moment. You know you have only to make the denominator in the bending moment equation what you like and you will get your stresses low enough to comply with any regulations.

Mr. Behar stated that he was of opinion that regulations framed for the purpose of becoming official and legal should not impose formulæ, but only principles, enabling formulæ to be established; or, in any case, if formulæ are given, he was of opinion that these should be given as examples of what would be required, but that these particular formulæ alone should not actually be imposed.

Mr. Etchells suggested that if principles only were given, very few architects, surveyors, magistrates, or builders would be able truly to affirm whether the statical requirements of the regulations had been complied with. If merely principles were laid down, we should require to be Rankines, Clapeyrons, and Eulers as well, to convert the basic principles into a form that would be suited for the practical work of design. Basic principles might please the professor of engineering, but would they help the busy builder who had to put up buildings in a hurry?

Mr. Behar stated that he was of opinion that an engineer or architect who may be called upon to apply regulations concerning reinforced concrete should have a sufficient knowledge of the laws of mechanics to be able to deal with the various problems which he may have to study, and to oblige him to follow certain formulæ would practically imply that he was incapable of exercising proper control of any scheme or problem in reinforced concrete which he may have to consider.

Mr. Etchells held that such a conclusion was unjustified. The architects and engineers were consulted before any regulations were sent forward to the allowing authority. Then, since the architects and engineers were consulted before the regulations were made, such consultation effectively admits their competency, not only to carry out the works, but to criticise the draft and to participate in the work of law-making.

He maintained also that it would be easier to see whether a particular design complied with certain stresses than it would be for the building authority, or any officers of the building authority, to discriminate as to who were competent, and who were not. That would be a very arduous task, and a very difficult task, and one open to very grave abuses, and it is much easier to judge a plan than to judge a man.

Valparaiso Harbour Contract.

Messrs. S. Pearson and Son, Ltd., have secured the contract for the new port of Valparaiso. The amount of the contract is £2,600,000, and the time allowed for the construction of the port is seven years. The work will involve: Dredging in sea bottom—677,700 cubic yards. Filling for reclaimed areas—2,752,400 cubic yards. Granite rubble for breakwaters and foundations for quay walls—1,604,600 cubic yards. Concrete in breakwaters, quay walls, etc.—425,640 cubic yards. Iron and steelwork—13,600 tons. Railway and crane tracks—14½ miles.

PATCHING AND REPAIRING CONCRETE.

SOME INTERESTING EXPERIMENTS.

An investigation of current practice in patching and repairing plain and reinforced concrete to determine the most satisfactory methods has been made during the past year by the committee on masonry of the American Railway Engineering Association, and the results are summarised in its report.

Wet Method.—The surface of the old concrete is thoroughly roughened, cleaned, and drenched with water and covered with a cement grout. Then the new concrete is mixed to a sloppy consistency and applied, being held in place until set by forms. Many successes and many failures have followed this method. Where it has been successful the result probably has been due to painstaking care and expense in the preliminary cleaning, and thorough wetting of the old concrete surfaces before the new concrete is applied.

Moderately Dry Method.—The surface of the old concrete is thoroughly roughened, cleaned, and drenched with water, and powdered with cement or painted with cement grout, after which the new concrete is applied and thoroughly tamped against the old surface. Generally, such patches are kept moist by sprinkling with water for several days. The same comment is made on this method as on the wet method.

Dowel Method.—This is a modification of the two preceding, and is generally used for other than horizontal surfaces, although it may be applied to the latter. The new concrete may have any consistency to meet the particular conditions or the ideas of the engineer, but usually a fairly wet concrete is used. The method includes drilling holes and setting dowels into the old concrete, with projecting ends to engage the new concrete. Sometimes steel bars or metal fabric are connected to the dowels to insure permanency of the patch. The committee observes that this method can be made uniformly successful, but cannot always be applied. Where any considerable mass of new concrete is to be connected to old concrete, it is believed to be the only safe method.

Wedge Method.—This includes the cutting out of defective concrete in such a manner as to undercut the surrounding good concrete, so that the new concrete will be held in place by the shape of the binding edges. The difficulty of undercutting concrete so as to secure such edges is pointed out to be too great to make this method applicable in ordinary cases, and, except where a considerable depth of new concrete is to be put in, such undercutting could not be successfully done.

Cleaning with Steam.—The surface of the old concrete is brushed as clean as possible with stiff brushes, and then gone over at least twice with a steam jet. A piece of ½-in. gas-pipe is stated to make a satisfactory nozzle. This pipe is connected to a steam hose so that it can be readily moved about. The steam is supplied by the boilers of the mixer or hoisting engines. The steam will clean and heat the concrete surface, leaving it perfectly dry, so it is important to drench the surface thoroughly with water after cleaning with steam. In cold weather it is found advantageous to use hot water. Immediately after the surface is cleaned and drenched, the new concrete is applied. Excellent results have followed the use of this method, but it is essential that the surface of the old con-

crete be drenched with water after using the steam jet.

Cleaning with Acid.—This includes washing the old concrete with a solution of hydrochloric acid, one part acid to two parts water, after which the surface must be carefully washed to remove free acid. This is very commonly applied in cleaning old concrete preparatory to placing new concrete against it, and is considered by many the only safe one to use, especially where a finish coat is to be put on.

From a study of the material collected, the committee has prepared conclusions which are in substance as follow:

In all cases the surface to be repaired must be thoroughly cleaned of all loose material, etc., and the clean, rough, sound concrete exposed to receive the patch. Probably the best method of cleaning is by means of a steam jet. The surface to be repaired must then be so thoroughly drenched that the old concrete will not absorb water from the new mortar or concrete used in patching. If possible, the surface should be kept covered with water for several hours.

If the repair is to be made on a vertical or sloping surface, and is not to be more than $1\frac{1}{2}$ in. thick, the surface of the old concrete should be spattered with a cement grout, while it is still wet, following this immediately with a fairly stiff plaster coat of mortar made of the same proportions of cement and sand as used in the original concrete, but never richer than 1:2 $\frac{1}{2}$. This coat should not be thicker than $\frac{1}{2}$ in., and each coat should be forced into the surface, but not dragged with a trowel. The surface of each coat, except the final, should be scratched to give a bond for the next. This plastering should preferably begin at the top and proceed downward, and only enough time should be allowed to permit each coat to receive its initial set before the next is applied. The final coat should be finished with a wooden float, and only enough water should be used to finish the surface properly. The patch should be kept damp and protected from sun or frost till fully set.

If the repair or finish coat is to be made on a horizontal or nearly horizontal surface, the old concrete should be slushed and broomed with a thin grout, following this immediately with a wet 1:2 $\frac{1}{2}$ mortar, using sand or granite screenings, and of the full thickness required, but not less than $\frac{1}{2}$ in. When the mortar begins to take its initial set, it should be floated or trowelled to a finish.

If the repair is to be made on a vertical or sloping face, and is to be more than $1\frac{1}{2}$ in. thick, it is advisable to embed dowels into the old concrete, as deeply as the thickness of the proposed patch and spaced sufficiently close to anchor the patch firmly to the old concrete. The dowels must be wedged into the old concrete, and it is advisable to fasten wires, metal fabric, or bars to them, in the case of extensive patching, as a safeguard. The patching may then be done with mortar without forms, or with wet concrete supported by forms, depending upon the thickness and the extent of the patch.

If the repair is to be made on a horizontal or nearly horizontal face, and is of considerable thickness, dowels may be used, or the concrete may be reinforced by fabric or bars without using dowels, treating the patch as a block of masonry.

Care must be taken not to have thin edges on patches. To avoid this, it may be necessary to cut out sound concrete around a place to be patched, so as to give deep edges to the patch. If possible, the edges should be undercut.

CALCULATING THE STRENGTH OF STEEL PILLARS.

BY W. CYRIL COCKING.

The author offers an approximate method of calculating the strength of steel pillars, using constants based upon the London Building Acts, 1909, Amendment.

THE formulæ for steel pillars included in the London Building Act, 1909, Amendment, having rendered necessary the revision of most tables of strengths of pillars, in order that they may comply with the above-mentioned Act, the following methods are suggested; and although it cannot be claimed that they give entirely accurate results, the time and labour saved in calculation will more than compensate for the slight error incurred.

The omission of the radius of gyration in these formulæ renders it unnecessary to calculate the moment of inertia, which up to the present has been indispensable in calculating the strengths of struts.

It will also be noted that the weight per foot run of cross-section is used in preference to the area of cross-section, which it is hoped will facilitate the calculations in estimating.

A steel merchant's stock list of sections giving weights per foot run in lbs. and over-all dimensions in inches will provide all the information required.

List of Symbols Used in Calculations.

- A = Area of cross section of pillar in square inches.
- C = Constant depending on the shape of cross section.
- D = Dimension in inches of cross section qualified by constant "C."
- E = Eccentricity Factor.
- F = Constant depending on fixture of ends of pillar.
- L = Safe load in tons.
- M = Factor which multiplied by "D" will give maximum length of pillar with fixed ends.
For one end fixed and other end pin-jointed take $\frac{5}{8}M$.
For both ends pin-jointed take $\frac{5}{8}M$.
- W = Weight in lbs. per foot run of cross section. Equal to $3\cdot4$ A.
- x = Eccentricity of load in inches.
- L_E = Equivalent Centric load due to eccentricity of loading, equal to $L(1 + Ex)$.
- H = Height of pillar in feet.
- D_{MAX} = Depth over section perpendicular to neutral axis.

Formulae:

$$(1) L = W \left(F - \frac{CH}{D} \right)$$

$$(2) W = \frac{L}{\left(F - \frac{CH}{D} \right)}$$

Values of F.

- (A) For both ends fixed = 1·91.
 - (B) For one end fixed and other end pin-jointed = 1·62.
 - (C) For both ends pin-jointed = 1·32.
- By using formula (2) a considerable amount of time can be saved in arriving at the approximate weight per foot run of strut or pillar.

For example, take case 16 (see diagram on next page).

We have a load of 511 tons to carry on a length H of 30' - 0". We will assume that triple joists will be employed and that the plates are 20" wide. The centres

of joists should be equal to about $20' \div 3$, say 6 $\frac{2}{3}$ ".

Then by inserting these values with the constants for case 16 in formula (2) we have that

$$W = \frac{511 \text{ tons}}{\left(1\cdot91 - \frac{1\cdot03 \times 30'}{6\frac{2}{3}"} \right)} = 356 \text{ lbs. nett wt. per foot run.}$$

By adding say 10 lbs. for rivet-heads, the gross weight per foot run of section should be about 366 lbs.

This is all we require for estimating. Now, when we require to detail the stanchion, we can find several sections which will fulfil the assumptions we have made, and will also have a nett weight of about 356 lbs.

- (a) 3 I_s. 16" × 6" and 20" × 2 $\frac{1}{2}$ " in plates = 18 $\frac{1}{2}$ " × 20" @ 356 lbs.
- (b) 3 I_s. 15" × 6" and 20" × 2 $\frac{3}{4}$ " in plates = 17 $\frac{3}{4}$ " × 20" @ 364 lbs.
- (c) 3 I_s. 14" × 6" @ 57 lbs. and 20" × 2 $\frac{3}{4}$ " in plates = 16 $\frac{3}{4}$ " × 20" @ 358 lbs.
- (d) 3 I_s. 14" × 6" @ 46 lbs. and 20" × 3 $\frac{1}{4}$ " in plates = 17 $\frac{1}{4}$ " × 20" @ 359 lbs.
- (e) 3 I_s. 12" × 6" @ 54 lbs. and 20" × 3" in plates = 15" × 20" @ 366 lbs.
- (f) 3 I_s. 12" × 6" @ 44 lbs. and 20" × 3 $\frac{1}{4}$ " in plates = 15 $\frac{1}{4}$ " × 20" @ 353 lbs.

This example has an error of 3 lbs. on the wrong side, which represents about ·85 per cent. or 4·35 tons on the load of 511 tons, which is negligible.

- (g) 3 I_s. 10" × 6" @ 42 lbs. and 20" × 3 $\frac{1}{2}$ " in plates = 13 $\frac{1}{2}$ " × 20" @ 364 lbs.
- Checking the ratio of centres of joists to depth over plates, we have D_{max} = $\cdot48 \times 13\frac{1}{2}" = 6\cdot48"$ against the 6 $\frac{2}{3}"$ we had assumed.

This stanchion will practically have the same strength taken about either axis.

We have therefore seven different sections, varying in weight from 353 to 366 lbs. per foot run, which will fairly accurately comply with all our assumptions.

It will be seen that there is no "trial and error" to obtain a suitable section (except in cases 12 and 22) with its consequent waste of time, but that a section is immediately arrived at.

It is not advisable that these formulæ should be used by students or those who do not possess some practical knowledge in the design of structural steelwork, etc., because these formulæ do not give any clue to the accepted theories for the design of stanchions; and also the choice of the most economical section to be employed to carry any given load depends on the position of the stanchion or strut in relation to the whole structure, the maximum external dimensions that can be allowed, the conditions of fixture at the ends, the proper proportions of the various parts of a cross-section (such as the thickness of webs and the projection of flange plates beyond flanges, etc., etc.), and the distribution of the area of cross section, a combination of conditions which only a good working experience can satisfactorily provide.

THE CONCRETE INSTITUTE.

Annual Dinner.

The second annual dinner of the Concrete Institute took place on May 9th, in the Empire Hall at the Trocadero Restaurant, Piccadilly Circus, W., Mr. E. P. Wells, J.P., president, in the chair. Among those present were the following: Mr. W. E. Riley, F.R.I.B.A., M.Inst.C.E., Superintending Architect of Metropolitan Buildings and Architect of the London County Council; Mr. R. Elliott-Cooper, M.Inst.C.E., President-elect Institution of Civil Engineers, chairman of sectional committee on bridges and general building construction of the Engineering Standards Committee; Mr. H. Percy Boulnois, M.Inst.C.E., Vice-President Concrete Institute, chairman of council of the Royal Sanitary Institute; Mr. E. A. Stickland, President of the Institution of Municipal Engineers, Borough Surveyor, Windsor; Mr. John Murray, F.R.I.B.A., Crown Surveyor; Sir W. Alfred Gelder, M.P., F.R.I.B.A.; Sir Henry Tanner, C.B., I.S.O., F.R.I.B.A., Past President of the Concrete Institute, Principal Architect to H.M. Office of Works; Mr. W. J. Downer, I.S.O., J.P., Assistant Inspector of H.M. Office of Works; Lieut.-Colonel G. E. Holman; Mr. F. E. Wentworth Shields, M.Inst.C.E., Vice-President Concrete Institute, Dock Engineer of the London and South-Western Railway; Captain A. Boyd Carpenter, ex-Mayor of Harrogate; Professor J. H. Cormack, B.Sc., Assoc. M.Inst.C.E., Professor of Mechanical

Engineering, University College, London; Mr. H. H. Dalrymple Hay, M.Inst.C.E., chief construction engineer, Underground Railways, London; Mr. C. R. S. Kirkpatrick, M.Inst.C.E., chief assistant engineer, Port of London.

In proposing the toast of "The Concrete Institute," Mr. W. E. Riley said he congratulated the Institute upon the great success which had been achieved already. Pioneer work was generally a very thankless task. He suggested that those who had inaugurated the Institute had very far-reaching thought; because, whether we liked it or not, concrete and reinforced concrete generally had come to stay. Those who had been through an architectural training understood the difficulties involved; but he believed that the man who is going to make a mark in life is the man who would show adaptability and commercial interest. He had heard men say they were sorry that someone had discovered that putting steel down concrete made it strong; the commercial world was not sorry for that—it was going to be glad. The aims of concrete experts had been greatly aided by three or four changes in the law which, though based on rigid principles, would be found to be more elastic in application than might be thought, and encouraged the application of new materials. He had recently been at the Architectural Congress at Rome, where he was glad to find that a good deal of time and consideration were given to the question of the design of reinforced concrete, though the conclusion there was that no one knew how to treat it. Some thought it thin and expressionless, etc.

But the right thing would evolve. He thought the aims of the Concrete Institute would result in obtaining proper and artistic expression by those who were trying to interpret building materials. He felt somewhat diffident in speaking to an Institute like this about regulations; but the onerous duty had been thrown upon him of trying to do something to put the regulations upon a proper footing. Nothing could be absolutely ideal, but the regulations should be made as ideal as could be. Any amount of personal effort had been expended on the endeavours to make them so. Those in authority at the London County Council had gone to every possible source of information that could be ascertained, and the regulations in force in other countries had been analysed and codified. The L.C.C. authorities were deeply grateful for the enormous assistance which they had had from this Institute. He was glad to have this opportunity of thanking the Institute for the great help they had given him personally in endeavouring to make those regulations such that they would be workable and practicable. Of course, he was not going to say anything more about the regulations, because they were at the moment *sub judice*, but he hoped that they would soon appear. He could not help adding this about the long-looked-for regulations—that they aim at trying to help all thoroughly, and to do what was wanted, namely, to give a fillip to the industry, and to give the benefit of much thought and experience to those who were willing and anxious to give commercial development to concrete work.

TABLE FOR CALCULATING THE STRENGTH OF STEEL PILLARS (see p. 535).

Mr. E. P. Wells, J.P., President of the Concrete Institute, said that in thanking Mr. Riley for the kind words he had said on behalf of the Institute, he also thanked him for the extremely impartial attitude that he had taken all through the negotiations that had passed between Mr. Riley and the Concrete Institute in regard to the new regulations about to be laid down for reinforced concrete. He trusted that the negotiations which were about to be carried on by the Local Government Board would be conducted in the same spirit as existed between the Concrete Institute and Mr. Riley. One thought struck him in connection with the Titanic disaster, and that was if London was frozen up and half the mains were frozen, any large conflagration would result in one of the most appalling disasters that had ever taken place. The regulations put forward by the London County Council had for their primary object the protection of life and property. Personally he would uphold those regulations throughout, because he felt convinced that though possibly they might at first appear a little hard, still they were for the benefit of London as a whole. If buildings could be put up which could be made absolutely fireproof, though this provision might be more costly at the outset, it would be cheapest in the long run, and therefore he was of opinion, from what he had seen and what he had had to do with the Building Acts, that they might be made more strenuous than at the present time. He hoped that, if anything was done in the future for their amendment, certain clauses would be added so as to place everything in such a condition that, given a building in accordance with the regulations, there would be perfect certainty that, in case of fire, very little damage would be done outside the building where the fire originated. There might be one or two present who thought that the regulations were a little hard, but he thought that when the Act was thoroughly gone into and applied it would be found that they would be beneficial all round. Next session the Council of the Concrete Institute were going to inaugurate educational lectures, primarily for the benefit of the younger men; but he trusted that they would be attended also by some of the older men, so as to give every help to the lecturer. He was happy to say that the total number of members was 920, and he hoped that before the present year was out the number would be 1,000, and that within the following year or so it might increase to 2,000.

Mr. F. E. Wentworth Shields, Vice-President Concrete Institute, in proposing "The Visitors," said that so large a membership for so young an institute was extremely gratifying. Moreover, it might be justly claimed, and they were able to say, that the work which they had already done had been useful not only to structural engineers, but to the world at large, and particularly to the citizens of London. They were able to say they had formed rules by which the regulations and the drawing of reinforced concrete designs would in future be simplified. They were able also to say with satisfaction that Parliament had entrusted them with the work of offering criticism and suggestions as to the rules which the London County Council had drawn up for the guidance of builders in reinforced concrete. Turning to the subject of this toast, he said that there were so many distinguished guests that it would take too long to mention them by name.

Lieut.-Colonel Holman responded.

Sir Henry Tanner, F.R.I.B.A., proposed the toast of the President, Mr. E. P.

Wells, which was drunk with musical honours, and Mr. Wells briefly responded.

Annual General Meeting.

In the afternoon of the same day the annual general meeting of the Concrete Institute took place in the Institute's lecture hall at Denison House, 296, Vauxhall Bridge Road, Westminster. Sir Henry Tanner, C.B., I.S.O., F.R.I.B.A., presiding. The following were elected members of the Institute: C. W. Ballenden, engineer on South African Railways; S. Edwards, architect and quantity surveyor, Barnstaple; C. T. Lewis, structural engineer, Ilford; H. Lingard, engineer on Madras and Southern Mahrattan Railway; J. P. Pike, Assoc. R. San. I., M. Inst. San. E., Southend; A. R. Sage, assistant principal of London County Council School of Building, Brixton, S.W.; I. M. Sutherland, structural engineer, Victoria, Australia; Allan Graham, A.R.I.B.A., architect and surveyor, London, W.

The annual report of the Council was adopted unanimously. The following extracts from it will be found of use and interest. The report states that:

The Concrete Institute had on April 30th, 1912, 881 Members, 24 Students, and 11 Special Subscribers.

The Council has in the past year been concerned with numerous technical and administrative matters.

One of the principal items occupying the attention of the Council and a Joint Committee of the Science and Reinforced Practice Standing Committees has been the consideration of the proposed Regulations made under the provisions of Section 23 of the London County Council (General Powers) Act, 1909, with respect to the construction of buildings wholly or partly of reinforced concrete. A draft of suggested Regulations was submitted by the Superintending Architect of the London County Council to the Institute for its consideration, and the action taken was recorded in the Annual Report for the 1910-11 Session. The 1909 Act referred to provides that the Concrete Institute, together with the Institution of Civil Engineers, the Royal Institute of British Architects, and the Surveyors' Institution, shall have notice of the Council's intention to apply to the Local Government Board for the allowance of any regulations as to the use of reinforced concrete in the county of London, and such notice was duly given at the beginning of December, 1911. The Institute's suggestions as to the amendment of these regulations have been sent to the Secretary of the Local Government Board and to the Superintending Architect of the London County Council, and in due course the Council of the Concrete Institute will be able to inform the members as to the outcome of such action.

In October, 1911, a proposal for widening the scope of the Institute was considered by the Council and referred to a Committee, whose report was approved on March 14th, 1912. The members of the Committee are: Mr. E. F. Etchells (chairman), Professor Henry Adams, Mr. Alexander Drew, Mr. Charles F. Marsh, Mr. W. G. Perkins, Mr. Edwin O. Sachs, Mr. H. D. Searles-Wood, Mr. L. Serrallier, Sir Henry Tanner, and Mr. E. P. Wells.

A seal, medal die, and certificate of membership have been designed and engraved for the Institute by Mr. Cecil Thomas.

The question of awarding a bronze medal for the best paper read in the previous session was decided by ballot among the members of Council, and as a result the medal has been awarded to Pro-

fessor Beresford Pite, F.R.I.B.A., for his paper entitled "The Aesthetic Treatment of Concrete."

As regards the work of the Science Standing Committee, the Institution of Municipal and County Engineers requested the opinion of the Concrete Institute upon a Standard Specification for Concrete Flags which they proposed issuing, and the Committee made a number of suggestions which the Institution has intimated will be considered in any revision they may make in the future of their Specification. The Standard Notation for calculations for reinforced concrete which was drafted by the Science Committee and approved by the Council continues to meet with favour, and has been adopted by the Joint Committee on Reinforced Concrete appointed by the Royal Institute of British Architects in their Second Report, and by the London County Council in their proposed regulations covering the erection of buildings of reinforced concrete in London. Authors of text-books have also employed it, and the American Joint Committee on Concrete and Reinforced Concrete have informed the Science Committee that they have the Notation under consideration with a view to its adoption in any further Report they may make. The Committee have the following matters under consideration: (1) Reinforced-concrete piles. (2) A chemical test for steel used in reinforced concrete. (3) The standardisation of attachments or joints in reinforced concrete. (4) The adhesion of or friction between concrete and steel. (5) A standard notation for calculations in structural engineering generally. (6) A standard specification for reinforced concrete work. (7) The effect of sewage on concrete. (8) The effect of oils and fats on concrete.

The Science Committee have appointed four representatives of the Institute upon the Joint Committee on Loads on Highway Bridges which is conducted by the Concrete Institute. The Joint Committee has had one meeting, and has issued enquiry forms to municipal authorities and others soliciting information respecting the vehicles that have to be sustained in various parts of the country as a preliminary to drafting recommendations.

The Tests Standing Committee have issued reports on "The Testing of Concrete, Reinforced Concrete, and Materials Employed Therein" and "The Testing of Reinforced Concrete Structures on Completion." These have been discussed at ordinary general meetings of the Institute. The Committee have the following matters under consideration: (1) The effect upon steel of the presence of sulphur in aggregates. (2) The grading of aggregates. (3) The expansion and deterioration of concrete due to changes of atmospheric temperature. (4) The effect of the use of sodium silicate on the surface of concrete as affecting reinforcing metal. (5) The erratic results obtained by the Vicat needle in ascertaining the initial set of cement.

The Reinforced Concrete Practice Standing Committee have drafted reports on the subject of "The Standardisation of Drawings for Reinforced Concrete Work" and "The Consistency of Concrete," which have been discussed at ordinary general meetings of the Institute. The Committee have also had under consideration a reference of the Council for a report as to clauses in contracts for reinforced concrete work, but the Committee recommended the Council that they were of the opinion that the formulation of clauses in contracts was a legal matter, and the Committee did not feel they were capable of formulating such clauses. The Committee are still investigating: (1)

Methods of treating the surface of concrete. (2) Cracks due to the expansion and contraction of reinforced concrete.

The chairman then read the report of the scrutineers on the annual election of members of Council. This resulted as follows: Mr. H. K. G. Bamber, F.C.S., F.Soc. Chemical Industry; Mr. H. Percy Boulnois, M.Inst.C.E., F.R.San.I., F.I. San.E., P.P.Inst. Mun. and County Engineers; Mr. Alexander Drew, M.I.Mech. E.M.Inst. Engineers and Shipbuilders in Scotland, Mem. Soc. Arts; Mr. Matt. Garbutt, F.R.I.B.A., Assoc.M.Inst.C.E.; Major R. Napier Harvey, Royal Engineers; Mr. John Munro; Mr. A. Alban H. Scott, M.S.A., F.Inst. San. Engineers; Mr. H. D. Searles-Wood, F.R.I.B.A., F.R.San.I.; Mr. L. Serrailier, Mem. Perm. Inst. Assn. Navigation Congresses, Mem. Perm. Inst. Assn. Road Congresses; Mr. T. B. Shore; Mr. R. W. Vawdrey, B.A.(Cantab.), Assoc.M.Inst. C.E. The above form only a portion of the Council of the Institute, the total

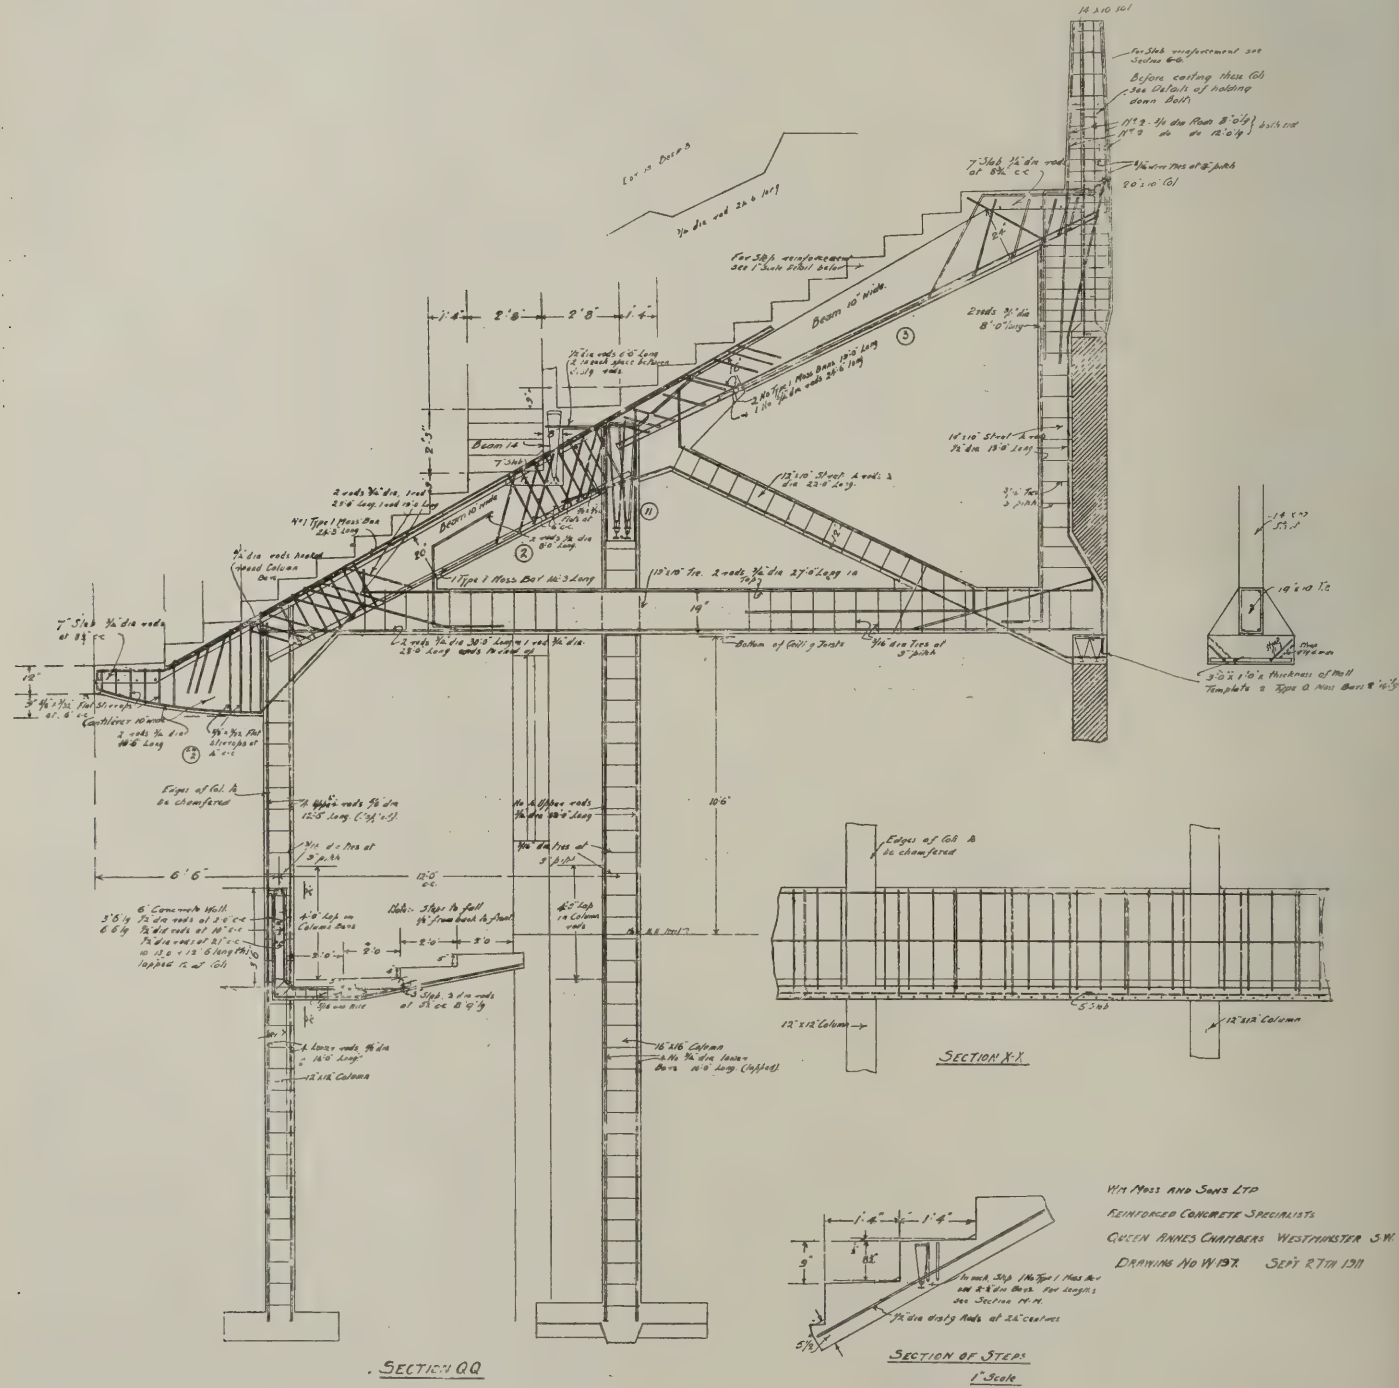

number of which is 32, only a small number being due to retire each year.

The auditors of the accounts were appointed, and the chairman then presented the medal which is to be awarded annually for the best paper read in each session. This is the first occasion on which the medal has been awarded, and it was presented to Professor Pite, F.R.I.B.A., for his paper entitled "The Æsthetic Treatment of Concrete," which was read in the 1910-11 session. Sir Henry Tanner, in presenting the medal, said that Professor Pite's paper was a most interesting contribution to the literature of the subject treated, and it gave rise to some little discussion.

Professor Pite, in reply, said that his paper had dealt with an aspect of work in concrete that had not yet captured the imagination of members of the Concrete Institute. He hoped it would in the future, as one could not but be sure that if the apparent fog that hung over progress in the architectural aspects of concrete con-

struction were dispelled by a little clear light there ought to be a considerable acquisition of width and breadth to the operations of this Institute. So long as that subject remained unexplored the Institute would be looked upon as merely a body concerned with certain aspects of building only; and concrete construction would be relegated to the larger, coarser, and greater class of building, when it might, if there were interest and enthusiasm and hope and light, be used for more monumental, more decorative, and more homely, and therefore much wider purpose.

It seemed to him that since it was recognised that there was a field for experiment, for movement, for intellectual thought—a field which connected a decent contract in concrete with an ordinary and regular course of architectural study—then there would be the widened scope which their Special Committee so hoped for, and which they had in a way suggested by adding the word "Architects" to the

REINFORCED CONCRETE RACECOURSE STAND, WARWICK.

REINFORCED CONCRETE RACECOURSE STAND, WARWICK.

title of the Institute. He suggested that the Concrete Institute should hold an annual competition in reinforced concrete design.

The chairman, as retiring president, then installed Mr. E. P. Wells, J.P., as president of the Concrete Institute for the ensuing two years of office.

Mr. A. Alban H. Scott, M.S.A., M.C.I., in moving a vote of thanks to Sir Henry Tanner, said that he had given an immense amount of time to the affairs of the Institute, and the courtesy which he had shown to everyone could never be exceeded.

REINFORCED CONCRETE RACECOURSE STAND, WARWICK.

We publish in this issue illustrations of the New County and Tattersall's stand which has just been erected at Warwick Racecourse. The new structure is carried out wholly in reinforced concrete. A noticeable feature of the design is the pierced concrete parapet which divides the upper and lower steps of the stand. The appearance of steepness is thus avoided, while the architectural effect obtained is considerably assisted by the double flights of steps placed symmetrically on either side of the centre line, as shown in the accompanying photographic illustrations.

The new stand has been erected as a self-supporting structure over an existing building. It is carried by reinforced concrete stanchions and beams, as illustrated by the cross section, thus enabling the old building to be retained.

The stand was designed and carried out by Messrs. William Moss and Sons, Ltd., of Queen Anne's Chambers, Westminster, S.W., to the instructions of the late Mr. A. E. King, architect. It was favourably commented upon, from the racing point of view, by the "Evening News" expert on the occasion of the recent Warwick races; and from the architectural standpoint it may be regarded as an admirable design in reinforced concrete.

A ROOF SHIELD IN REINFORCED CONCRETE TUNNEL CONSTRUCTION.

Recent improvements on the Metropolitan Railway system of London, of which we gave an illustrated account in our issues of April 17th and April 24th, include the widening of the St. John's Wood section of the line, involving the demolition of an existing double-track brick tunnel and the substitution of a considerably wider structure built of reinforced concrete and heavy steel roof girders. The difficulties of the work were increased by the necessity of providing against any interference with the traffic, which amounted to about 700 trains daily over this section. This traffic was only suspended between 1.35 and 3.50 a.m., and hence did not give sufficient time for the erection of temporary supports for false-work if that method of conducting the work had been feasible. The small clearance, about 4 in., between the rolling stock and the intrados of the arch made it necessary to use some other means of support for the required shield.

The problem was solved, according to a recent issue of "Engineering," by the use of a suspended steel shield or hood of the type shown in the sketch (p. 540) reproduced. This shield, which was designed by Mr. H. A. Bartlett, of Messrs. Perry and Co., Ltd., who were the contractors on the work, served to support the old

REINFORCED CONCRETE RACECOURSE STAND, WARWICK.
A. E. KING, ARCHITECT.

tunnel section during the work of demolition and to protect passing trains from any debris that might result from the conducting of the work.

The shield comprises a $\frac{1}{2}$ -in. steel plate 28 ft. wide by 11 ft. long, curved to fit the tunnel roof and braced with four light steel trusses with angle-bar stiffeners. These

stiffeners extend along the inner surface of the shield to a point a short distance above the clearance line of the railway coaches. A short length of shield was required on account of the curvature of the line over this section. The four trusses are supported by, and bolted to, two 12 in. by 6 in. I-beams 32 ft. long and placed 8 ft. apart parallel to the axis of the tunnel. The I-beams are suspended from the heavy girders of the new work by means of four stirrups on screw couplings. These girders were placed temporarily across and above the old tunnel section at 10 ft. intervals, and stirrups were suspended from the lower flange of these girders and passed through holes cut in the tunnel roof. The supported I-beams rested on roller bearings, which thus furnished a means of readily moving the shield ahead as the work progressed.

When in use the shield is drawn closely up to the roof by means of the screw couplings, thus permitting the demolition of a 10-ft. length of the brickwork down to about 12 in. above the springing line of the arch. After the traffic is suspended, the shield is lowered about 12 in. in similar fashion and moved ahead for the removal of another section of the roof. The shield was made 11 ft. long to allow the front end to project 12 in. under the next section of brickwork, and at the back a light vertical screen about 2 ft. high is placed to prevent material from falling on the tracks below. Small slots are provided in the plate for the supporting stirrups. The total weight of the shield is a little over five tons, and about one hour is required to move it from one working position to the next.

A NEW TYPE OF STEEL AND CONCRETE CONSTRUCTION.

A type of construction somewhat different from the ordinary is employed in the First Baptist Church of Syracuse, at present under construction. This method, according to the architect, Mr. Gordon A. Wright, is quite similar to the usual steel construction where the steel is fireproofed with concrete and reinforced concrete floor slabs are used.

A light construction is first erected, which supports the forms for floor slabs and girders. This light construction consists, first, of riveted-up structural members, which form part of the column reinforcements, second, of pairs of channels which are later imbedded in the girders; and third, of reinforced concrete beams,

which are made up and hoisted in place as the steel is erected.

Figs. 1 and 2 show the construction of the columns and girders. The structural steel members are designed to have sufficient strength to act as columns and support the construction loads of one storey. Where the columns are large, the steel is erected in place and the concreting done at the same time that the girders and the floor slabs are constructed. Where the columns are small, they are made on the ground, and erected as the steel channels and concrete beams are erected.

In the girders the two channels are used largely as a convenience in the construction. They are bolted to the structural steel of the columns, and also to stirrups cast in the ends of the concrete beams. Their purpose is to hold all other members exactly in position. They are designed to have sufficient strength to support the loads of construction when a temporary post is set under the centre of each girder. The lower flanges of the channels are so placed in the girders that they will be stressed to 16,000 lb. when the reinforcing rods are stressed to 20,000 lb. The steel in these lower flanges is figured as part of the reinforcement that resists bending. In addition to these uses, these channels are sufficient to take all the shear stresses. They make the girder practically safe under all conditions of construction. While half of the steel in these channels is useless after the building is erected, this is relatively a small item.

The reinforcing rods which are added to the girder are wired in place after the concrete beams have been set. These are so designed that they carry the loads of the concrete beams up into the top of the girders and distribute them on to the channels.

Fig. 3 shows the construction of the reinforced-concrete beams. Several deformed bars are used in the bottom of the beams, to resist bending. As soon as these bars reach the point where they are not required to resist the bending moment, they are bent up so that the same bars take care of both bending and shear stresses; and stirrups are not required. One of these bars, amounting to one-third of the reinforcement against bending, is carried to the top of the beam, over the support, and anchored into the girder as

shown in Figs. 2 and 3. This construction gives a bending moment for the clear span between the girders of $WL/10.67$. This is equivalent to a bending moment of $WL/12$ where the span is taken from centre to centre of the girders. And this is the rule required for computing bending moments of continuous beams in the building codes of most American cities.

Mr. Wright states that there is an endless number of ways that these connections between the beams and girders may be made. The principal difficulty arising is a practical one, of allowing a sufficient leeway for the rods not being accurately cut and bent. This is taken care of in the construction shown. There is no difficulty in setting the stirrups in exact position in the forms, and a sufficient leeway can be readily left for inaccuracy in bending the end rods.

As to the efficiency of this connection, he states that a one-fourth full-sized model of two beams and a girder was loaded to destruction without showing any cracks at the connection.

In designing the beams which are to be hoisted, it is desirable that they be made as light as possible. The reinforcements are therefore arranged as shown in Fig. 3, the web of the beam being only sufficiently thick to properly fireproof the steel. The upper part of the beam is widened to give sufficient compressive area, but since it is imbedded in the floor slab, it is safe to assume a much higher unit strain than is usually allowed. The concrete is held against expanding, the same as in the case of a hooped column. The dotted lines, Fig. 4, show the compressive area that would be regarded if the beam was not imbedded in the slab. Mr. Wright states that several quarter-sized models of these beams have been made and tested, and that no difficulty was found in stressing the steel beyond its elastic limit without otherwise affecting the material of the beams.

The advantages of this construction over the monolithic construction are, first, safety, as there is no danger of a collapse while the building is being erected; and, second, economy. He notes that the small beams can be erected at less cost than they can be constructed in place. One beam a day can be made in a mould, and the beams can be erected when a week old

under ordinary weather conditions. The small columns can be made on the ground and erected very much cheaper than they can be constructed in place. This is quite an item where a skeleton concrete construction is used.

The false-work for supporting frames is done away with, and the number of forms required for floor slabs and girders can be largely reduced, as a continuous process of changing forms and placing concrete can be carried on. To use this construction an expensive concreting plant is not required, and therefore the overhead expenses are reduced.

To the architect superintending the work (Mr. Wright states) this method of construction presents the following advantages: When the rods for the beams are bent in accordance with details, the workmen cannot fail to get them in accurate position; and he has only to inspect the made-up beams to be sure that the steel is all there and properly placed. The girder reinforcements are much more easily inspected when wired to the channels than when placed in the usual trough. Further, it is a great convenience in designing to be able to concentrate a load at any point on the girder without having to change the general method of reinforcing, so as to provide for unusual shear at that point.

The building under construction in which this method is employed is known as The Temple, and is built in the English Gothic style, supporting light towers without spires. It includes two large galleried auditoriums with rooms for the various church needs, above which are three storeys of dormitory construction. Another example of a different type is the Edwards building at Rochester, which is 68½ ft. by 70 ft. in area, five storeys high, and designed for storage or light manufacturing.

THE ANCIENT ORIGIN OF IRON AND STEEL.*

BY SIR ROBERT HADFIELD, F.R.S.
(SHEFFIELD).

The use of iron, including in this term the combination of iron and carbon known as steel such as produced by the fusion or cementation processes, has without doubt existed from a time dating back to a very early period in the world's recorded history. Owing, however, to the avidity of the oxygen present in the air for this metal, it has been most difficult to obtain *ancient* specimens of iron. We have therefore but little definite evidence regarding its early manufacture and use. It is for this reason, the author thought, that the present description of some interesting Sinhalese specimens of this nature which came under his notice during a recent tour in the East would be of interest. Whilst information available from the East regarding iron of ancient production is fragmentary, yet undoubtedly a comparatively high state of metallurgical art and knowledge must have prevailed, not only centuries but more than a thousand years ago.

In the Colombo Museum the author inspected a set of ancient specimens of iron and steel which were obtained from some of the buried cities of Ceylon. These cities date back from about 500 B.C. This collection, which was formed quite recently, and has not been previously known or described, is in many respects unique, and the author was accorded the privilege of having placed at his disposal

a few of the specimens for investigation. Whilst there is often an impression that the use of iron, including in this term the alloy of iron and carbon known as steel, is a modern development, this is probably incorrect, as without doubt such knowledge really dates back to the earliest stages of tradition. The ancient Indian method of making steel in clay crucibles seems to be identical with the method thought to have been invented in England in the middle of the eighteenth century.

It has been asserted that the Egyptians knew how to harden copper so that it could be made to take and keep a cutting edge under the severe working stresses to which the tool must have been subjected in order to produce the hundreds of thousands of forms now to be seen in the Nile Valley from Cairo to Khartoum or beyond, over a distance of some 2,000 miles. Such work must have involved the labours of immense numbers of stonemasons, who would require tools. The author is strongly of opinion that no method of hardening copper was then known which would produce tools having a hard cutting edge, or which were at any rate at the same time tough enough to stand the severe impact blows such as stone-cutting work required. Copper alloyed with other elements can be hardened, as was recently evidenced in a paper read by Dr. Rosenhain and Mr. Lantsberry before the Institution of Mechanical Engineers. During the course of the discussion on the paper it was stated that a turning tool had been made which had cut iron. The author is of opinion, however, that such a material made up into chisels, wedges, and the like, would be of little value for hewing to shape and finishing the gigantic works in stone of the Egyptians.

It is far more probable that the ancient Egyptians were not only able to make steel for tools of all kinds, but also to cement and harden it; or, if they were not themselves steel workers, they obtained the necessary material and help from the workmen of another nation. There is, indeed, evidence that such was the case, and the facts available suggest that in the art of steel-making Egypt received assistance from India or China. There are, it is true, but few specimens of iron or steel tools or implements in and from Egypt. There is, however, a scythe of iron in the British Museum; examination shows it to be in such an oxidised condition that it is not possible to say definitely what is the nature of the material, although it is undoubtedly iron. This scythe, which the author has seen and handled, is so thin and corroded that it would almost fall to pieces unless most carefully dealt with. There is also an important specimen of iron taken from the Great Pyramid. In determining this general question as to the use of steel by the Egyptians, it should be remembered that there are several ways of endowing iron with the quality of hardening—that is, after heating and quenching it in water, or other cooling medium. The material ordinarily termed wrought iron can be made to acquire or take up carbon by cementation. This process is still largely carried out in Sheffield, principally upon bars which are by these means carburised with required varying percentages of carbon. These bars are chiefly made for the purpose of afterwards being melted into crucibles to produce the highest and purest qualities of steel. Such cemented steel, or "blister" steel, is in some cases directly worked up into tools having cutting edges, and is then termed bar steel. This aspect of the case is referred to because even if ancient specimens of highly

carburised steel are not available, it must be remembered that wrought or forged iron itself can be cemented or carburised, or the edges of tools can be so treated.

There is reason to believe that this knowledge, although in a crude form, was possessed by ancient workers in iron. Such methods may probably be regarded to a certain extent as "case-hardening." In such process the surface of the material to be treated must have been placed in a gaseous medium, or in a medium of charcoal or other pure form of carbon, then heated, and the surface carburised to the desired extent and depth. Such material, when again heated and quenched, would carry a cutting edge.

Somewhat singular to say, this knowledge appears to have been possessed; and to be proved in an interesting manner by one of these Sinhalese specimens which the author has examined, namely, a chisel which is proved to have its edges cemented or carburised.

The other and chief method of producing "cast steel"—that is, an alloy of metal with carbon varying from about 0.50 to 1.80 per cent., is, of course, by direct fusion of bar iron, or, in the case of a steely iron made in the manner just referred to, in a closed receptacle or "crucible." To accomplish this is required a high technical knowledge, for it is not merely necessary to obtain the requisite quality of bar or melting iron, practically free from or very low in sulphur and phosphorus, but there has also to be solved the equally difficult problem of preparing a receptacle or crucible to withstand handling at the high temperature required to fuse the materials being melted, and also the intense heat to which it is subjected without itself fusing. It is interesting to observe that in the Colombo Museum clay crucibles (of modern manufacture, it is true) can be seen, but apparently the same method has long been known and practised in the East. Therefore our modern belief that such method originated in Europe is probably not correct.

As before mentioned, the specimens in the Colombo Museum were taken from the ruins of some of the buried cities of Ceylon. No fewer than about fifty different articles are comprised, including those for agricultural implements, cutting instruments, tools for building and other trades, warlike implements, and general articles. Whilst the Sinhalese temples and monuments are of much later date than those of Egypt, nevertheless, in view of the metallurgical knowledge which was evidently possessed at a very early period in India and later in Ceylon, it is quite evident that the knowledge then prevailing in these matters must have been considerable. There is no evidence that the metallurgy of iron was understood in Egypt; it seems more than likely, therefore, that, as has been suggested by several authorities, aid was obtained by the Egyptians from the Far East—no doubt India or China, whence there was a constant stream of trade and commerce. They were thus enabled to carry out their many wonderful works in stone, including temples, pyramids, statues, obelisks, sarcophagi, sculptured walls, figures, tombs, steles, and the like, many of them prepared from the intensely hard Assouan granite, also red and black granite, quartz, porphyry, limestone, and sandstone. Some of the hieroglyphics have been found cut to a depth of no less than 2 in. To carry out such work would require tools of excellent quality.

In the Colombo Museum there are several hundreds of these ancient iron specimens. They comprise large and small chisels, including stone-cutting chisels,

* Extracts from a paper read before the Iron and Steel Institute.

about $2\frac{1}{2}$ in. in length and $\frac{1}{2}$ in. in diameter, axes, adzes, hoes, wedges, scissors, locks, keys, and many other articles. As regards the age of the specimens, Dr. Willey, F.R.S., the then Director of the Colombo Museum, states that this is vouched for by those thoroughly competent to make the statement, and that the specimens are 1,200 to 1,800 years old. They are in a remarkably good state of preservation, and many of them being quite bulky offer much better scope for examination than anything of the kind the author had ever seen or heard of. There seem good grounds for the assumption that the requisite skill and knowledge required for steel-making probably reached Ceylon from India.

One of the most notable ancient specimens of iron is the famous Pillar of Delhi, which is not the less interesting when we find it is stated that the city itself, "Imperial Delhi, the capital of all India," as Sir Alexander Cunningham in 1864 termed it, owed its name to this pillar. In the light of recent political events, this prophetic utterance is now an actually accomplished fact, for on December 12th, 1911, Delhi was made the capital of our great Indian Empire.

The iron pillar at Delhi is one of the most curious monuments in India. Whilst there are many large works of ancient times in metal, for example the Colossus of Rhodes, the gigantic statues of the Buddhists, and others, these were of brass or copper, all of them hollow and built up of pieces riveted together, whereas the Pillar of Delhi is a solid shaft of wrought

iron, upwards of 16 in. in diameter and 22 ft. in length, welded together, although the welding is not altogether perfect. In any case, it was a very creditable piece of work for a metallurgist of at least 1,600 years ago. At one time, owing to its peculiar colour or hue, it was thought to be of "mixed metal" or even bronze, this belief probably arising from the curious yellow appearance of the upper part of the shaft. A small fragment from the rough lower part of the pillar, which was submitted to Dr. Murray Thompson, of the College at Roorkee, for analysis, was found to consist of "pure malleable iron of 7.66 specific gravity." Practically pure iron (99.87 per cent. iron) has a specific gravity of 7.8477. Therefore, the material of this pillar could not have been pure. Probably it was a somewhat inferior type of wrought iron, permeated with slag, and high in phosphorus, like the Sinhalese specimens described by the author in this paper. Pure iron, having the specific gravity mentioned, would weigh 490 lbs. per cubic foot, the Delhi Pillar, with 7.66 specific gravity, would weigh 477 lbs. per cubic foot. The actual date of its first appearance is probably about A.D. 300. The height of the column above the ground was stated by Lieutenant Spratt, of the Royal Engineers, to be 24 ft., and the depth below ground 3 ft. He said that the column or pillar ends in a bulb like an onion, which is held in place by eight short thick rods of iron, on which it rests, and which at their lower extremity are let into blocks of stone, in which they are secured

by lead. The iron of which the pillar is made seems to have been originally in blooms of about 80 lbs. weight each.

The iron pillar at Dhār or Dhārā (the ancient capital of Malava, and thirty-three miles west of Indor), which was described by Mr. Smith in a paper to the Royal Asiatic Society in 1898, had a total length of no less than 42 ft. This is specially interesting owing to its extraordinary length. The three existing pieces measure 24 ft., 12 ft., and 6 ft. in length, aggregating 42 ft., in addition to a missing fragment, so that if these figures are correct, the column is approximately double the height of the Delhi pillar.

Mr. Smith rightly says: "Whilst we marvel at the skill shown by the ancient artificers in forging the great mass of the Delhi pillar, we must give a still greater measure of admiration to the forgotten craftsmen who dealt so successfully in producing the still more ponderous iron mass of the Dhār pillar monument with its total length of 42 ft., which, like the pillar at Delhi, is of the Gupta period, or about the year 321 of our Christian era."

There are also in existence in India several very large iron girders at Puri, ornamental iron gates of ancient origin at Somnāli, and a wrought-iron gun, said to be 24 ft. in length, at Nuwiri.

The author has given a detailed description of these two pillars, as they form the only known ancient large masses of iron in the world, so that they are indeed remarkable. But little more than a generation has elapsed since objects of this size were made possible, even in our time.

Having described in detail the results of his exhaustive tests of the objects from the Colombo Museum entrusted to him for investigation, the author said that it is important to know whether the facts stated in this paper warrant the conclusion, as they appear to do, that knowledge existed in ancient times with regard to hardening carburised iron. If they do, we should then have a satisfactory explanation of how the great works of stone, such as those seen in Egypt, were carried out in past ages—that is, probably by means of iron or steel tools, hardened and tempered to carry a cutting edge.

At the meeting at which this important paper was read "Further Notes on the Early Use of Iron in India" were communicated by Mr. H. G. Graves, of Calcutta, who confirms many of Sir Robert Hadfield's observations with regard to early proficiency in the making of iron in the East.

Surveyors' Institution Examinations.

The results of the recent Final Examination at the Surveyors' Institution are as follow: Mr. Harold G. Buss, Dover (the "Galsworthy" prize); Mr. C. A. E. Eachus, Enfield (the "Crawter" prize); and Mr. Arthur E. Jewell, St. Albans (Penfold Gold Medal). In the Intermediate Examination the following students head the list: Mr. H. J. Smith, Blackheath ("Institution" prize); Mr. Leonard A. Hempson, Ipswich ("Special" prize); and Mr. Richard Elphick, London, W. ("Quantities" prize). The prizes for non-student candidates were won by Mr. Ernest R. Canham, East Finchley ("Driver" prize and Penfold Silver Medal); Mr. Frank Dyer, Bradford, bracketed with Mr. Frank H. Heaven, Bridgend, and Mr. Gerald Hines, East Boldon, Durham (the "Building" prize); and Mr. A. C. Pawson, Watlington (the "Beadel" prize). The Scottish Committee's prize has been awarded to Mr. J. Loring Tweedie, Dumfries.

Shakespeare's England at Earl's Court.

PERHAPS "Shakespeare's London" would be a more suitable title for the show at Earl's Court than the larger title adopted, for what the scenic display really shows is the general aspect of city streets three hundred years ago. The Elizabethan gateway, with a distant perspective of Hatfield House in the rear, which faces the visitor oppo-

site the Warwick Road entrance, is not very promising; but when we come into the mimic town the impression is very satisfactory. We have the narrow, irregular streets and the picturesque houses, with their projecting upper storeys and half-timber work, all of which is very well carried out, and if we could only have had the cobblestone streets the illusion would have been almost complete. They would have been uncomfortable to walk on, it is true, but they would have given us the real effect of the ancient city; walking over boarded floors between the houses, one is constantly reminded that it is only a piece of scenery; one might almost have forgotten this otherwise.

Occasionally we have completely stone architecture in very late Gothic—the side of a church, for instance, and in the case of this, and of the houses altogether built in stone, the oversailing upper storey is not employed. When you see the narrow streets with the projecting upper storeys in timber work you realise what was the object of this method of building—to leave as much width as possible to the street and gain some additional space on the upper floor. That this was the common method of building in towns is brought home to us by Shakespeare himself, in the remark put into the mouth of Salario in the "Merchant of Venice," speaking of the anxiety he should feel if he had ships at sea:—

"Should I go to church,

And see the holy edifice of stone,

And not bethink me straight of dangerous rocks?"

Evidently Shakespeare did not see much of stone buildings in cities except in the churches. That Venice at that very time was full of splendid stone buildings would not trouble Shakespeare in the least; he took his scenery from the city that was familiar to him; there is no indication that he had any picture of the actual Venice in his mind; there is not a reference to such things as canals and gondolas. The scenic direction runs, in more than one case, "A Street in Venice," but in the author's mind it was a street in London. That seems absurd from our travelled point of view, but it gives the more value to Shakespeare's hints of the topography in his plays, as indications of the character of English cities of his day.

The "Official Guide" (which, except for its plan of the exhibition, does not give much practical information) contains a good article by Mr. Thornton-Smith on Tudor domestic architecture, in the course of which he remarks on the influence of locality on architectural treatment: "Did building stone exist in the neighbourhood? Then

stone would there be the predominant feature of the house" ("predominant material," it should be). "Was stone scarce? Then brick and timber provided the wherewithal of construction, for transport by land was always difficult, and by sea often impracticable." That is, in fact, the great distinction between ancient and modern conditions of building; facility of transport of materials has gone far to destroy local character in building. But the half-timber house, as Mr. Thornton-Smith admits later on, often found favour even where stone abounded. Of course, for one thing, it was cheaper to work than stone, but in towns another reason no doubt was that which is illustrated at Earl's Court—that space could be saved for the width of the street and regained in the upper storey of the buildings.

The centre portion of the block of buildings at the farther side of the Shakespeare town shows a portico which represents the first efforts of the Renaissance in England, in the shape of quasi-classical columns, crude in detail and clumsy in proportion. In the covered quadrangle behind this portico screen is what seems to be a reduced reproduction of the city cross at Winchester, or, at all events, something very like it. But the two most interesting things in the exhibition are no doubt the reproduction of Drake's ship, the "Revenge," and the reproduction of the Globe Theatre. These cannot be called models; they are a rebuilding of the ship and of the theatre, on the original scale, from documentary evidence. The ship does not come within our province,

A Street View.

"SHAKESPEARE'S ENGLAND AT EARL'S COURT.

except to remark that it is exceedingly well done, and that it is matter of real interest to see a fac-simile, actual size, of one of the ships which fought the Armada. But the Globe Theatre enables us to realise the arrangement and the conditions under which some of the greatest plays in any language were first produced. The Globe was a polygon erection, with so many angles that it approached pretty nearly to a circle, with three tiers of covered seats round it, a sanded pit in the centre, open to the sky, and a wooden stage projecting into the pit, with a curtain screen at the rear, from behind which the actors entered, but with no proscenium arch. The stage is open on three sides, and is looked down upon to its whole extent by the occupants of the upper gallery. Attempts are being made to give a realistic revival of the production of a play at the time when the Globe Theatre was

new (it had only a life of thirteen years); the noisy crowd of apprentices in the pit, the privileged fine gentlemen seated on chairs on each side of the stage, and the scene of the play of Pyramus and Thisbe from the "Midsummer Night's Dream," was acted with a good deal of spirit amid this revival of the original conditions. The auditorium, of course, except the pit, was occupied by a modern audience, so one did not get the entire verisimilitude of the ancient performance; but it certainly assisted one in realising for what kind of place and audience Shakespeare originally wrote. There is another attempt at realising this in Mr. Bundy's picture in the Academy, "The First Performance of 'The Merry Wives of Windsor,' 1599"; that is, the interior of the Globe Theatre, with an audience of the period, but it is rather crowded and confused in composition.

City Gate from inside, with Shops.

Tudor Buildings, Holborn Bars.

"SHAKESPEARE'S ENGLAND" AT EARL'S COURT.

We may refer again to Mr. Thornton-Smith's essay in the "Official Guide," to supplement his remarks on the reasons for the peculiarly attractive style of Tudor house architecture, as a class of building which arose when, after the introduction of artillery, castles were no longer effectual strongholds, when there was a reaction in favour of peaceable living, and men began to build themselves houses with the main object of being comfortable, with no special architectural mission to serve, but turning to the late Gothic of the churches and convents for suggestions in the architectural treatment of the dwelling-house. Beauty was not their object in building, but an architectural beauty was evolved through a simple and sincere treatment of the rather subdued style of late Gothic, with windows used just as they were wanted and not with the view of effect. Thus originated that peculiarly homelike style, not without dignity, which renders the English Elizabethan house unique as a representation of the architecture of the home.

A good deal of trouble seems to have been taken to give realism to the show by dressing a number of assistants in costumes of the period. We meet the guard on their rounds in a picturesque dress, with halberds and swords, and the Elizabethan admiral or captain, in his habit as he lived, comes up to parley with some one at the dockyard gate, and so on. One may be inclined to laugh at this as such an obvious piece of make-believe, but it has its picturesque effect, and it was interesting to hear Orlando Gibbon's lovely madrigal, "The Silver Swan," sung by a group of people and children dressed like those who may have sung it when it was first written. To cross the bridge into the outlying part of the grounds, with their shops, shooting-galleries, mountain railways, and what not, is to go from the picturesque to the vulgar aspect of life. But as to the exhibition proper we have nothing but congratulations for the supervising architect, Mr. E. L. Lutyens, F.R.I.B.A., and for the contractors, Messrs. Humphreys, Ltd., of Knightsbridge, by whom the whole of the Elizabethan buildings and streets have been modelled and built for Mrs. George Cornwallis-West.

A New View of College Architecture.

THE paper by a distinguished American architect, Mr. Cram, on American University architecture, read at the Institute of Architects on Monday last, was in a literary sense one of the finest papers ever read at the institute, not only in its substance, but in the admirable manner of its delivery; long as it was, we do not believe anyone found it too long; and it was not surprising that it evoked an unusual display of enthusiasm on the part of a very large audience. The subject matter was rather different from that which we usually expect from an American architect, for American architecture is usually presented to us as an art in which neo-Classic architecture, founded on *Ecole des Beaux-Arts* teaching, is the prevalent type. Mr. Cram, on the contrary, based his paper on a loving appreciation of the English collegiate type of architecture of the seventeenth or eighteenth centuries, and exhibited many photographs illustrating the treatment of the same type of architecture for the same class of buildings in the United States; claiming that in the States they were thus carrying on to its legitimate conclusion the type first elaborated in England, and that they were pursuing a logical course in doing so. One is so accustomed to the worship of everything French and the minimising of everything English by American writers on architecture, that this attitude of mind in regard to an important phase of our national architecture came as an agreeable surprise; but Mr. Cram is a Boston architect; and Boston, as is well known, has her own artistic and intellectual ideals, which are not exactly those of the United States at large; and she has no mania for high buildings and the commercial aspect of architecture. The lecture culminated with the description and illustration of the buildings on the splendid and romantic site at West Point, where America has established her great military training school-buildings, for

which the reader of the paper had himself been largely responsible.

Architectural Acoustics.

THE School of Architecture of Harvard University, to which, it will be remembered, M. Eugène Joseph Armand Duquesne, Grand Prix de Rome, was recently appointed Professor of Architectural Design, includes on its staff of thirteen instructors a lecturer on Architectural Acoustics. This is Mr. Wallace C. Sabine, A.M., whose extensive and peculiar knowledge of this rather recondite subject is made manifest in an instructive article which he contributes to the first issue of "The Architectural Quarterly of Harvard University"—a publication that, in substance and in appearance, is worthy of the best traditions of Harvard. The gist of Mr. Sabine's article, with some of the illustrations which accompanied it, are reproduced in another part of the present issue. In this important contribution to a subject that is too little understood, Mr. Sabine, while giving sufficient attention to theory, deals mainly with concrete examples in which he has been consulted as an expert of uncommon knowledge and experience. He disposes effectually of the notion that wires stretched across an interior are of any use in mitigating the nuisance from echo. He finds that they cannot affect sound either for better or worse, a fact that was prodigiously realised in a building in which nearly two miles of wire was put up, without the slightest effect except that of disfigurement. Sounding-boards he admits to be of some slight value occasionally; but he shows that the real remedy for bad acoustics is modification of the surfaces which give rise to them. The form or the substance may be to blame, and Mr. Sabine cites the curious case of a cylindrical smooth ceiling, which, by focussing a soprano voice along a focal line, caused it to be heard more sharply from the ceiling than from the singer. The remedy was to break the focal line by coffering the ceiling. The strange case of the hall of the House of Representatives at Rhode Island, where a speaker's words reflected from wall to wall, and then to the ceiling, whence they returned to the audience after an appreciable interval, with boomerang effect on the speaker, was set right by deadening the walls; and a sevenfold echo at the Metropolitan Museum of Art was cured by similar means.

Modernising Lyme Regis.

LYME REGIS is one of the few small towns of England which retain their ancient character almost unimpaired. It is a pity that there seems to be a move on the part of the town authorities to make a beginning in the direction of destroying its rather unique character in this respect. At the foot of the steep hill called Broad Street, the main street of the town, is a narrow street, Bridge Street, crossing a very ancient bridge connecting Broad Street with Church Street, a wider street going up the hill. The Corporation want to widen Bridge Street, an operation which will involve destroying an interesting old building known as the Fossil Shop, facing Broad Street. There seems really no adequate reason for doing this; Bridge Street is a very short street; and, as "A Ratepayer" of Lyme Regis writes to the "Times," the result of the narrowness of Bridge Street is that motor vehicles always go through it with caution, whereas if the street is widened they will go through faster and will be more likely to be dangerous to themselves and to others at the sharp turning into the foot of Church Street. The point of the whole matter, however, is that this will be the beginning of destroying the ancient aspect of Lyme; and when that kind of operation is once begun in a small town, it is likely to be the thin end of the wedge, and to lead to more alterations which will destroy the charm of the place. The Corporation would do well to remember that it is the picturesque and unspoiled character of Lyme Regis which is the attraction to visitors, and it is against their own interests to spoil it.

Mr. Cass Gilbert.

IN our issue for January 10th last, in connection with an illustrated account of the Woolworth Building, New York, we published a sketch of the architect, Mr. Cass Gilbert, which was made for us direct from life by Miss Farini. With this study Mr. Gilbert is not altogether pleased. "It has," he says, "an effeminate quality which I should be sorry to think would be carried down to posterity, if posterity is sufficiently interested in the subject to look at it." He, therefore, sends us a photograph in profile, which was taken about a year ago, and this we are pleased now to reproduce, as—to again

MR. CASS GILBERT.

quote Mr. Gilbert—"in the nature of a correction of an impression which the other drawing, however artistic, may give to those who do not know me." On another page of this issue we publish Mr. Gilbert's design for the grand staircase in the Wisconsin State Capitol—certainly a very masculine, vigorous conception.

Soil-Pipes and the Law.

A RATHER novel point was settled the other day, before the Lord Chief Justice and two other judges sitting in the King's Bench Court, in the case of the Marylebone Borough Council v. White. This was a special case stated by the police magistrate at Marylebone Police Court. The respondent, Sir E. White, in making alterations to the drainage of his premises, had fixed an iron soil pipe, the upper part of which was outside the premises, but the lower part was continued through a projecting back-addition, and was therefore inside the premises, and should, according to the by-law, have been of lead. Sir E. White, who had refused to alter the pipe on a summons from the authority to do so, seems to have relied (or his counsel relied for him) on the fact that there was no mention in the by-law of the case of a soil-pipe being partly inside and partly outside the premises, and that he was therefore entitled to consider it as an outside pipe which, through special circumstances, passed inside the building for a part of its length. The Court, however, refused to adopt this view, and allowed the appeal; considering that the by-law must be interpreted in its natural sense, viz., that any soil-

pipe within a building must be of lead, and the fact of part of the same pipe being outside the building did not invalidate the order for the part that was inside. There can be no doubt that the decision of the Court was reasonable, both in a logical and a hygienic sense.

It is, indeed, difficult to see how any other conclusion could have been anticipated. Sir E. White could hardly have hoped to win his case, and possibly he contested it with the object of drawing attention to what, on this showing, is an obvious defect of the law, which certainly ought to have been more explicit on a contingency, which, however, was apparently overlooked.

NOTES AT THE PARIS SALON.

AS with the Academy, so with the Salon—there is no really great picture this year; the general interest of the pictures is, however, quite up to the average standard. There are of course many uninteresting works and a good deal of what may be called artistic commonplace; but the number of pictures is so great that works which would attract a good deal of attention in the smaller area of Burlington House are almost overlooked at the Salon.

The large room at the top of the main staircase contains two important decorative paintings, one being the principal work of M. J. P. Laurens, the first celebration of the mediæval "Jeux Floraux," on March 3, 1324, a date which in itself suggests the kind of scene represented: a mediæval population seated under trees outside the city walls, listening to a troubadour on a platform in the foreground. It looks rather as if intended for execution in tapestry, though not so stated. The other is a great ceiling painting, by M. Gorguet, for the Salle des Mariages of a Mairie; it seems to symbolise the joy of life, but neither the title ("Prairial") nor the composition explains itself very well, and it is defective as a ceiling painting because it is essentially a vertical composition, which can only be looked at one way; a ceiling painting should always be an all-round composition. In the same room are M. Didier-Pouget's two landscapes: rather too scenic, but perfectly wonderful in their realistic power. We ought to have one or two of his landscapes at the Academy; they would make a sensation there—perhaps too much for the peace of mind of English landscape painters of the realistic school.

Perhaps the most perfect picture in the Salon is M. F. Humbert's "Portrait de Mlle. N—" (Gallery 37—we give the numbers of the rooms, as that is the only way of easily finding a picture). That represents the perfection of style in painting. M. Humbert is the modern Gainsborough, and he is every whit as good as Gainsborough. The tendency of some of the best French painters, in portraits of women, is to put too much glitter and brilliancy into the costume painting, so that it becomes a picture of the costume rather than of the person, a mistake M. Humbert never makes; he knows just where to stop. M. Paul Chabas (17), in "Matinée de Septembre," repeats, with a difference in lighting, a motive he has used once or twice before; a young girl standing in the shallow water of a lake, the water and landscape kept in a silvery shimmer which allows the blond head of the girl to stand out and yet retain its brightness. M. Maurice Chabas (21) has two twilight scenes in one of which, "Sérénité," a single small figure seated in the foreground seems to embody the sentiment of the scene.

M. Debat-Ponsan (23), who symbolised France last year as a white horse throwing over Napoléon, is still occupied with horses, but in "Ceux qui veillent" they are two chargers held in the foreground by the orderly dragoon while the officer uses his field-glass. M. Debat-Ponsan is usually either moral or patriotic in his art, but it is always capital painting. M. Tattegrain (13), another versatile painter of subject pictures, gives us this year

what is mainly a large and very powerful painting of cliff landscape, with two wolfish-looking figures, "sauveteurs d'épaves" (*anglicé*, "wreckers"), almost tumbling down the cliff path in their hurry to catch the spoil from the waves. Among figure pictures of the more imaginative type is M. Saintpierre's "La Fortune" (13), a nude figure, tiptoe on her wheel in the clouds, letting fall showers of coin from a cornucopia, while her eyes are veiled by the drapery caught round her head. It is an attempt to give a certain intellectual interest to a nude figure, and is what one may call a very effective piece of *bravura* painting. M. Lavergne's "Le Paradis Perdu" (30), Adam and Eve seated together in a twilight landscape, is a really fine piece of pictorial composition. Mme. Demont-Breton is herself again this year (her principal work last year was a failure) with "L'Aïeule" (32), a dear old peasant woman contemplating her sleeping grandson; M. Joseph Bail's "La Lectrice" (18) is a masterpiece of execution in the surroundings and of character in the two heads; M. Renard shows a rather pathetic picture of the death of Molière (8); and M. Roganeau (a name not familiar to us) exhibits a very large canvas, "Le Soir, à la Rivière" (6), a cold evening landscape with figures of women filling water-pots at the stream and walking away with them, which may be thought too large for the subject, but comes very near being a great picture; it is at all events solemn and impressive.

There are some very fine landscapes; M. Cabié's "La dune et le chêne vert" (37) is perfect in style and composition; M. Palézieux has a fine coast landscape (8); M. Ponchin has two fine landscapes in quite different styles, "Pines at Carqueiranne" (6), and "Sunset at Venice" (8). But the most powerful thing in the way of landscape is certainly M. Lefort-Magniez' "Surpris par la marée" (7), such an effect of storm in sea and sky as we have rarely seen on canvas; it is quite formidable to look at, and it is honest nature-painting, with no trick of effect or lighting.

On the staircase in the new Salon is an immense and rather fine decorative painting by M. Osbert, "Le Retour du Jour," which is a State commission—we are not told for what purpose; it is worth looking at, more so than M. Aman-Jean's "Les Elements," a large decorative painting commissioned by the State for an amphitheatre in the new Sorbonne, with allegorical figures of "Earth," "Air," "Geology," and other machinery of the kind. It is not beautiful either in colour or composition, and, in fact, goes to confirm our idea that M. Aman-Jean, who has a strong clique of admirers, is a painter a good deal over-rated. Among the smaller pictures in the New Salon, M. Béraud, in his "Chemin de Croix," repeats the idea which he has already exploited rather too often, of introducing the figure of Christ amid a rabble of modern personages; and M. Guillaume, in "L'Avis de la Famille," where a portrait is criticised by various members of the family (down to the little boy), exhibits an exceedingly amusing bit of pictorial satire.

As to the vast collection of sculpture (nearly 1,000 works) in the Old Salon, it is almost bewildering to try to say anything, as one would not know where to stop, there being so many things worthy of mention. M. Alfred Boucher may be said to have the honours of the year for two works of very different type; one the figure of a lady—said to be a portrait—clad entirely in close-fitting tights and buckling on a sword, with the title "S'il le faut"; the other, an exceedingly beautiful seated draped figure called "La Réverie." The large monumental works in the centre line of the hall are not so good as they sometimes are. M. Bacqué's monument to Michel Angelo shows him in a wide-brimmed hat, seated on horseback on the top of an immense rock, on the side of which are sculptured roughed-out reminiscences of some of his greatest sculptures: not a very happy idea. The colossal monument to "the glories of Toulouse," by M. Ducuing, on a triangular plan, has figures which are fine in themselves but too much detached from the centre erection. M. Laporte-Blairsy's monu-

mental fountain to the memory of Clemence Isaure (also to be erected in Toulouse) is clever and original, but the architectural details want conventionalising more. M. Jean-Boucher takes an historical subject, on a very large scale, "Réunion de la Bretagne à la France," which he treats as a group of personages in realistic robes and costumes, under the semi-dome of an apse; the long drapery of "La Bretagne" just saves the subject, which is not a good one for sculptural treatment. The two figures by M. Convers, "Inspiration" and "Harmony," to go on each side of the base of a column in the court of the new National Conservatoire of Music, form a noble piece of work. M. Allar exhibits a nude seated figure, with compasses in one hand and a large sheet in the other, who symbolises "Architecture," and M. G. Calvet an interesting model for a monument in honour of Aviation—"L'Univers acclamant les Conquistadors de l'Air"—a column crowned by a nude figure with aeroplane wings instead of arms, and standing on a wide circular base with a bas-relief of acclaiming figures. M. Mercié has a colossal draped bronze figure representing "Columbia," for some monument in America; there is a fine energy about it, but he has done more remarkable things than this. But among the works of more average size, single figures embodying various ideas, there are quite a number that are worth attention; it is impossible to enumerate them, and we can only recommend visitors to give more time and attention to the Salon sculpture than we fancy are generally accorded it. The annual collection of sculpture at the Salon represents a national energy and versatility in artistic production such as no other country can show.

THE LONDON SOCIETY.

THE second meeting of the London Society was held at the Suffolk Street Rooms on Thursday last. The general meeting, advertised for 8.15, was preceded by a business meeting, called for 7.45, at which Sir Aston Webb took the chair. A draft set of rules was submitted to and formally approved by the meeting, subject to one or two suggestions which the chairman undertook that the council should take into consideration. These were mainly in relation to the subscription, which had been fixed at a guinea. The amendment was moved that it be reduced to half a guinea on the ground that as it was desirable to influence public opinion as widely as possible it was much better policy to have a wide membership with a low subscription than a more restricted membership with a higher subscription; and we hope this suggestion will be adopted. At the public meeting Lord Plymouth took the chair, and made a few preliminary remarks as to the principles on which the society was founded and the kind of work it hoped to do, and Mr. Raffles Davison then read a paper, illustrated by a number of lantern slides, the special object of which was to show the need of improvement in London. The paper was a little too long, but was very amusing and trenchant in its criticisms, and a number of the lantern slides formed most dramatic illustrations of the ugliness, and the want of common thought and care as to appearance, which are so much in evidence in various parts of London. Against one of these satirical views, however, we must protest strongly. After a view of Blackfriars Bridge, with the railway viaduct behind it, a second specially prepared view was exhibited leaving out the railway viaduct, to show how much better the bridge looked without this background to it. Now the fact is that Blackfriars Bridge is one of the most offensive erections in London, a piece of bad, tawdry sham Gothic, while the railway bridge, though not beautiful, is not in bad taste, as it is merely construction with no attempt at ornament of any kind; and a piece of simple utilitarian structure is a great deal better than a piece of tawdry design pretending to be architectural. That illustration was a mistake, and should not have been shown.

NEW LIGHT ON ARCHITECTURAL
ACOUSTICS.

SINCE 1895 Mr. Wallace C. Sabine, A.M., has been constantly engaged in the investigation of the subject of architectural acoustics, and in 1900 he contributed to the technical Press an important series of articles embodying the work of the first five years and dealing mainly with the phenomena of reverberation. During the next five years he extended this enquiry over the range of the musical scale, and in 1906 published the results in the Proceedings of the American Academy of Arts and Sciences. Thereafter he directed his attention to interference and resonance, the effects of peculiarities of form, and the causes of variation in audibility in various parts of an auditorium, and he promises to publish the results during the ensuing year. In the meantime, being Professor of Physics and Lecturer on Architectural Acoustics in Harvard University, he has contributed to the "Architectural Quarterly" of the University, of which the first number has just been issued, an interesting and informative article, in which he considers some of the problems involved in the correction of the defective acoustics of completed buildings, reserving for future consideration the important subject of the preparation of plans in advance of construction; and the corrective methods here discussed are of comparatively simple character—the author describes them as "medicinal rather than surgical." In the cases cited there have been no radical changes in form, of dimensions, or in the positions of wall surfaces, or in ceiling heights.

Those old but nearly obsolete devices, stretched wires, and sounding-boards, Mr. Sabine discards, finding that the stretched wires are utterly valueless—devoid of scientific justification and showing no record of success, either when only four or five wires are stretched across an auditorium or when miles of wire have been stretched across one room. In a few instances in which the wires have been credited with some slight improvement in the acoustics it has been found that changes in form or occupancy have probably caused the beneficial change which has been attributed to the wires. Apart, however, from the absence of proof of effectiveness, there is, Mr. Sabine declares, no physical basis for the device. "The sound whose echoes these wires are presumed to absorb scarcely affects the wires, giving to them a vibration which is at most of microscopical magnitude. If the string of a violin were free from the body of the violin, if the string of a piano were free from the sounding-board, if the string of a harp did not touch the thin sounding-board which faces its slender back, when plucked they would not emit a sound which could be heard four feet away. The sound which comes from each of these instruments is communicated to the air by the vibration of its special sounding-board. The string itself cuts through the air with but the slightest communication of motion. Conversely when the sound is in the room and the string at rest the vibrating air flows past it, to and fro, without disturbing it, and consequently without itself being affected by reaction either for better or worse."

The value of the sounding board is not altogether denied, but has been over-rated. This subject, however, which Mr. Sabine seems to have investigated with characteristic thoroughness, he reserves for further discussion on a future occasion; contenting himself for the present with the statement that unless the sounding board is large the benefit from it will be but small.

Among the illustrations to Mr. Sabine's article are two (which are not reproduced here, as the following description will be found sufficiently lucid) of the Congregational Church in Naugatuck, of which Messrs. McKim, Mead, and White are the architects. It was built with a smooth cylindrical ceiling, of which the curvature was such as to have the effect upon a voice from the platform of focussing the sound, not at a point, but along a focal line. "The difficulty was evident with the speaking,

but may be described more effectually with reference to the singing. The position of the choir was behind the preacher and across the main axis of the church. On one line in the audience, crossing the church obliquely from right to left, the soprano voice could be heard coming even more sharply from the ceiling than directly from the singer. The alto, starting nearer the axis of the church, had for its focus a line crossing the church less obliquely. The phenomena were similar for the tenor and the bass voices, but with focal lines crossing the church obliquely in opposite directions." The defect was very satisfactorily overcome by breaking up the smooth ceiling into a series of coffers of sufficient depth to prevent the sound from travelling along a focal line.

Another type of defective acoustics is illustrated by the instructive (and it is to be hoped unusual) case of the hall of the House of Representatives in the Rhode Island State Capitol. Here there is, of course, no stated place from which the sound proceeds—that is to say, there is no platform or rostrum. Speeches are made from various positions on the floor of the hall. To about half the height of the room the walls were of stone, and above that they were of stone and plaster, and the ceiling, as will be seen from the illustration here reproduced, was coffered. The difficulty was that the sound of a speaker's voice, striking the side wall, was reflected across the room to the opposite wall and back again, to and fro, mounting gradually until it reached the ceiling. It was thence reflected directly down upon the audience. Although the ceiling had some curvature, this was not sufficient to produce a distinct focussing of the sound, but in the course of its travelling the sound met only feebly absorbent surfaces, and therefore returned to the audience with but little loss of intensity, and it came back after such an interval of time as to cause great confusion to the ear, though there was no distinct echo. The remedy adopted was that of diminishing the reflecting power of the two side walls, by placing a suitable felt on the plaster walls between the engaged columns and covering it with decorative tapestry. As may be easily inferred from the accompanying illustration, the design of the room very fortunately lent itself to an appropriate execution of this treatment; the result being as charming artistically as it is effective acoustically.

Mr. Sabine was not deterred by the problem presented by that Hall of the Seven Echoes—the lecture-room of the Metropolitan Museum of Art, New York. This hall is a semi-circular auditorium, with the semi-circle slightly continued by short straight walls. The platform (see illustration) is nearly, though not wholly, within a broad but shallow recess. The body of the auditorium is surmounted by a spherical ceiling, with short cylindrical extension following the straight side walls. In the centre of the ceiling is a flat skylight of glass. In this

HALL OF THE HOUSE OF REPRESENTATIVES, RHODE ISLAND STATE CAPITOL. MCKIM, MEAD, AND WHITE, ARCHITECTS.

room the reverberation was not merely excessive, but it resolved itself by focussing into a multiple echo, the components of which followed each other with great rapidity, but were distinctly separable. The number distinguishable varied in different parts of the hall. Seven were distinguished at different parts. To improve the acoustics the ceiling was coffered, the limiting depth and dimensions of this coffering being determined in large measure by the dimensions of the skylight. The semi-circular wall at the rear of the auditorium was transformed into panels, which were filled with felt, over which was stretched burlap, as shown in the second illustration of the pair representing this interior.

The foregoing cases, Mr. Sabine remarks, are comparatively simple. Complexity arises where various shapes give rise to different reverberations, each space "pouring sound into and receiving sound from others."

Cathedrals commonly present, in varying degree, the geometrical complications which lead to excessive reverberations, and the cathedral in Detroit, built from the designs of Messrs. Cram, Goodhue, and Ferguson, presented an interesting problem in acoustics. The nave, broad at one end and moderately narrow at the other, represented in effect two simply connected spaces, the lower space, when filled with people, being abundantly absorbent of sound, while the clerestory part was not absorbent. The corrective applied was felt placed in the panels of the ceiling, which felt, treated decoratively, produced highly satisfactory results acoustically as well as architecturally. Similar treatment was successfully applied to the high and reverberant transept, to the central tower, and to other parts of the building.

The New Theatre, New York (Messrs. Carrère and Hastings, architects), seating 2,300 persons, was improved acoustically by changing the position of the twenty-three boxes, and by correcting the excessive height of the main auditorium by the provision of an oval canopy (major and minor horizontal dimensions, 70 ft. and 40 ft.), which in effect lowered the height of the ceiling 20 ft., and has resulted in pronounced improvement.

In discussing the principles involved in the examples recorded above, Mr. Sabine says that when sound is produced in a confined auditorium it spreads spherically from the source until it reaches the audience, the walls, or the ceiling. It is there in part absorbed and in part reflected. The part which is reflected retraverses the room until it meets another surface. It is again in part absorbed and in part reflected. This process continues until, after a greater or less number of reflections, the sound becomes of negligible intensity. Thus at any one time and at any one point in the room there are many sounds crossing each other. In a very simple auditorium, such as a simple rectangular room with plain walls and ceiling, this process is not difficult to follow, either step by step, or by large, but entirely adequate, generalisations. When the conditions are more complicated it is more difficult to analyse; it is also more liable to be a vitally significant factor in the problem. That it has heretofore been inadequately discussed has arisen from the failure to take into consideration the phenomenon of diffraction in the propagation of a sound nearly parallel to an absorbing audience, the phenomenon of diffraction in reflection from an irregular surface, and, above all, the phenomenon of interference. The first of these three considerations is of primary importance in calculating the intensity of the sound which has come directly from the source, in calculating the effect of distance in the audience, and in calculating the relative loudness on the floor and in the gallery, and at the front and at the back of the gallery. The second consideration enters into the calculation of the path of the sound after reflection from any broken or irregular surfaces. The third is a factor of the utmost importance when the sounds which are crossing at any point in the auditorium are of comparable intensity and have travelled paths of so nearly equal length that they have originated from the same element. This latter calls for a more elaborate explanation.

In both articulate speech and in music the source of

sound is rapidly and, in general, abruptly changing in pitch, quality, and loudness. In music one pitch is held during the length of a note. In articulate speech the unit or element of constancy is the syllable. Indeed, in speech it is even less than the length of a syllable, for the open vowel sound which forms the body of a syllable usually has a consonantal opening and closing. During the constancy of an element, either of music or of speech, a train

of sound waves spreads spherically from the source, just as a train of circular waves spreads outward from a rocking boat on the surface of still water. Different portions of this train of spherical waves strike different portions of the auditorium and are reflected. After such reflection they begin to cross each other's paths. If their paths are so different in length that one train of waves has entirely passed before the other arrives at a particular point, the only phenomenon at that point is prolongation of the sound. If the space between the two trains of waves be sufficiently great the effect will be that of an echo. If there be a number of such trains of waves thus widely spaced, the effect will be that of multiple echoes. On the other hand, if the two trains of waves have travelled so nearly equal paths that they overlap, they will, dependent on the difference in length of the paths which they had travelled, either reinforce or mutually destroy each other. Just as two equal trains of water waves crossing each other may entirely neutralise each other if the crest of one and the trough of the other arrive together, so two sounds, coming from the same source, in crossing each other may produce silence. This phenomenon is called interference, and is a common phenomenon in all types of wave motion. Of course, this phenomenon has its complement. If the two trains of water waves so cross that

the crest of one coincides with the crest of the other and trough with trough, the effects will be added together. If the two sound waves be similarly retarded, the one on the other, their effects will also be added. If the two trains of waves be equal in intensity, the combined intensity will be quadruple that of either of the trains separately, as above explained, or zero, depending on their relative retardation. The effect of this phenomenon is to produce regions in an auditorium of loudness and of comparative or even complete silence. It is a partial explanation of the so-called deaf regions in an auditorium.

It is not difficult to observe this phenomenon directly. It is difficult, however, to measure and record the phenomenon in such a manner as to permit of an accurate chart of the result. Without going into the details of the method employed, the result of these measurements for a room very similar to the Congregational Church in Naugatuck, is shown in the accompanying chart. The room experimented in was a simple rectangular room with plain side walls and ends, and with a barrel or cylindrical ceiling. The ceiling of the room was smooth like the ceiling of the Naugatuck Church before it was coffered. The result is clearly represented in the diagram illustrating distribution of intensity, in which the intensity of the

Diagram showing distribution of sound intensity on head level in room having barrel-shaped ceiling with centre of curvature on floor level.

sound has been indicated by contour lines in the manner employed in the drawing of the geodetic survey maps. The phenomenon indicated in this diagram was not ephemeral, but was constant so long as the source of sound continued, and repeated itself with almost perfect accuracy day after day. Nor was the phenomenon one which could be observed merely instrumentally. To an observer moving about in the room it was quite as striking a phenomenon as the diagram suggests. At the points in the room indicated as high maxima of intensity in the diagram the sound was so loud as to be disagreeable, at other points so low as to be scarcely audible. It should be added that this distribution of intensity is with the source of sound at the centre of the room. Had the source of sound been at one end and on the axis of the cylindrical ceiling, the distribution of intensity would still have been bilaterally symmetrical, but not symmetrical about the transverse axis.

A full discussion of this phase of the subject Mr. Sabine

reserves for another paper, which is now about ready for publication.

If a sound of constant pitch is maintained in an auditorium, though only for a very brief time, the sound spreading directly from the source, together with the sound which has been reflected, arrives at a steady state. The intensity of the sound at any one point in the room is then the resultant of all the superposed sounds crossing at that point. As just shown, the mutual interference of these superposed sounds gives a distribution of intensity which shows pronounced maxima and minima. However, the probable intensity at any point, as well

as the aggregate intensity over the room, is the sum of the components. Whatever the distribution of maxima and minima the state is a steady one so long as the source continues to sound. The steady condition in the room is such that the rate of absorption of the sound is equal to the rate of emission by the source.

If after this steady state is established the source is abruptly checked, the different trains of waves will continue their journey, the maxima and minima shifting positions. Ultimately the sound will cease to be audible, having diminished in intensity until it has passed below what aurists call the "threshold of audibility."

The curves in the accompanying diagram show the efficiency of various coverings. Curve 1 is the normal exposed efficiency of the felt above referred to. Curve 2 is its efficiency when covered by burlap attached to silicate of soda. This covering was so sized as to be practically impervious, but was in contact with and a part of the felt. Curves 3 and 4 show the efficiency of coverings which are not in contact with the felt, but which are stretched. Both coverings are impervious—3 relatively light, 4 heavy. Number 3 weighs 0.87 ounces to the square foot; number 4 weighs 2.58 ounces to the square foot. The materials of which these coverings are made have no bearing on the question, and would be misleading if stated. The really significant factors are their weight, the tension with which they are stretched, their elasticity, and their viscosity. The weight of the several coverings has been stated; the other factors can be defined best by means of their independent absorbing powers. Lower curves 3 and 4 indicate the absorbing power of the membrane coverings alone. It is interesting to note that the diaphragm which has by itself the least absorbing power has the greatest absorbing power when combined with the felt. This is by no means a paradox. It is exactly the result which could be predicted by application of the simplest of physical principles.

It is sincerely to be hoped that Mr. Sabine will collect the important papers on this important subject which he has contributed to various periodicals, and issue them, together with the as yet unpublished results of his patient, long-continued and thoroughly scientific studies, in volume form. Such a book would at once become a standard authority on a subject which the author has made peculiarly his own.

Curves showing the sound-absorbing qualities of different materials. Curve 1, felt; 2, burlap cemented with silicate of soda; 3, light membrane as described; 4, heavy membrane as described; lower curve 3, light membrane alone; lower curve 4, heavy membrane alone.

RECENT UNIVERSITY ARCHITECTURE IN THE UNITED STATES.*

BY RALPH ADAMS CRAM, F.A.I.A., F.R.G.S., LITT.D.

In one of the best-written and best-read papers ever heard at the Institute, Mr. Ralph Adams Cram traced the history of college building in the United States, and incidentally revealed himself as an enthusiastic lover of collegiate Gothic.

ALTHOUGH in the conception of colleges in the United States there has been from time to time a yielding to novel impulses, there is always a return step by step to the old ideals and sound methods of English colleges, for with the reaction towards a broader culture comes the return to the architecture of Eton and Winchester, Oxford and Cambridge, that so fully expressed that very culture itself.

Dearth of Early Work.

Of course, practically all the seventeenth century work, and nine-tenths of that of the eighteenth, is gone, including much of the best; but fortunately at Harvard there remains a notable group that has yielded neither to vandalism nor conflagration. The typical English quadrangle arrangement was abandoned for a grouping of isolated buildings, at first more or less formal, then developing into final chaos as other men with other minds came on the scene and placed their buildings, and designed them also, at their own sweet will. As for the material, it was almost invariably brick, at first imported from the old country, for the visible stone supply in New England was intractable granite; and even where a kinder material was available, there was in the beginning little skill in cutting, and later little money to pay for the labour involved. With few exceptions the trimmings of doors and windows and cornices were delicately moulded wood painted white, the Vignolan laws as to proportion being intelligently modified to fit the new material, while the roofs were covered with split shingles.

The "Jeffersonian" Style.

The first evidence of decadence appears in the advent of that more pompous style Jefferson did so much to advance. Hitherto what had been done was done simply and unaffectedly: now came the conscious desire for architecture, which is a dangerous ambition at best. At the University of Virginia we have the original setting out, almost intact, and if we deplore the unnecessarily unreasonable classical porticoes with columns, entablatures, and pediments complete—and all built of pine boards framed up in the semblance of a newly discovered Paganism—we must admit the great dignity of the plan and the singular charm of the ensemble.

This "Jeffersonian" style rapidly took the place of the old Georgian, but its day was brief, and somewhere between 1820 and 1830 occurred that ominous point when the last flickering tradition of good taste and the last weak impulse of instinctive art vanished—for the first time in history—and the new era began wherein the desires and predilections of society as a whole were no longer for good things and beautiful things, but explicitly and even clamorously for bad things and ugly things, while the uncertain offices of the architect were the only agencies that from time to time redeemed the general chaos.

"Not Very Gothic."

Fortunately there was little collegiate building with us during this dismal second

quarter of the nineteenth century, or, rather, and also fortunately, little of it has survived, and when first the architect appears on the scene as the mentor rather than the exemplar of public opinion, it is in novel guise; nothing less, indeed, than as the protagonist of Gothic. He was not *very* Gothic, I must admit, and in the beginning he contented himself with a few apologetic and quite casual buttresses, pointed arches over his door and window openings, an octagonal turret or two, and, of course, battlements, usually of two-inch deal neatly painted, and sometimes sprinkled with sand as a concession to appearances. What took place in domestic and ecclesiastical architecture I dare not even reveal to you, but the college work was a shade less horrific, for sometimes, as at West Point, it was of stone, and good stone work will cover a multitude of sins—as it still does in our own day and generation, I believe.

From the close of the war between the States down to about 1880, the new Gothic that expressed Ruskin's really enormous influence might be said to have run riot through our colleges. There were those like Renwick and Congdon, and Mr. Haight, who is still living, that held conscientiously to the grave and archaeological type established by the Pugins; there were others who tried to incorporate Ruskinian doctrines in more personal, original, and mobile work, as Blomfield and Butterfield were doing here in England; the results were at least lacking in monotony, but few of them achieved the simplicity and the dignity of Mr. Haight's work, while many of them reached a point of violence and anarchy hardly to be matched in history.

Richardson's Great Work.

It was all a "false dawn," however, and ceased almost in a moment (though for a brief period only) when that great genius and greater personality, Richardson, flashed like an unpredicted comet across the sky. The later 'seventies were desperate, no less, and the group of conscientious men could not withstand the flood of falsity and bad taste and artificiality that involved the whole art of architecture. Richardson alone turned the tide; and deliberately forced a new and alien style on a bewildered people. He did great work, some of it immortal work, in his powerful mode, but he died before his mission was accomplished, and though he killed the "French roof style" and the futile Gothic, and all the other absurdities, he left behind no one of his own calibre to carry on the crusade, but instead a multitude of imitators who, though at first doing fine work under the memory and inspiration of their master, gradually turned away into other fields, leaving the Romanesque propaganda to the most inadequate exponents imaginable. For a decade we wallowed in Lilliputian cyclopænia, and then, to change the simile, the summer storm swept west and south, and over the desolation it had left loomed, almost simultaneously, three new tendencies—Colonial, Perpendicular Gothic, and "Beaux-Arts." With a magnanimity rare in history, these three rivals more or less succeeded in establishing a *modus*

vivendi, Colonial taking over part of the new and again triply dividing Gaul in the shape of domestic work, Gothic annexing so far as it could all collegiate, scholastic, and ecclesiastical building, while to the Beaux-Arts propaganda fell all it could get of the rest—particularly Carnegie libraries, town houses, and banks. As a matter of fact, this partitioning of architectural activity was not the result of amity, nor was it in the least definitive; the Colonial style claimed the patronage of our Nonconformist brethren (with show of reason and propriety); Gothic tried vainly to break into the library fold; while the Beaux-Arts architects made unavailing eyes at the Church, and, indeed, claimed everything in sight. Their pretensions did not go without questioning, however, for in the meantime the old and most classical classic was reborn (it had never wholly died), and at the hands of Charles McKim it suddenly achieved a height of serene nobility where it could and did challenge the claims of its rivals. And there were other claimants for the architectural crown now so completely "in commission"; there was the Spanish pretender, with its doubtful offspring, the quaintly denominated "Mission style," there was the secessionist Americanism of the inspired but unguarded Mr. Sullivan; there was a kind of neo-Byzantinism; there was a hidden but persistent Japanese propaganda. In fact, I was wrong when I said that the Architectural Gaul was divided into three parts; it is not such a triple partition that confronts us now; it is an omnivorous eclecticism that bears some of the earmarks of anarchy. To use one of our own phrases, "everything goes," and much of it goes exceedingly well, amazingly so, in fact, but the result is somewhat lacking in the qualities of unity and lucidity.

Georgian or Gothic—Which?

Fortunately we have to do with few of the varied schools, for though all of them have footholds in the several colleges, only two have established their claims—Georgian and Gothic, and at the present time the latter has the call and has produced the most notable results; it may almost be said that except where lack of funds or climatic conditions argue against Gothic, this has the field absolutely to itself. The ascetic and fastidious classicism of McKim created Columbia University, and occurs sporadically elsewhere; the Boulevardesque of the Beaux-Arts men appears in a single building at Yale and in the slow-growing University of California and the Naval College at Annapolis; Spanish elements go to the making of Leland Stanford, and in Texas my own firm is doing "a deed without a name" that you must judge for yourselves and justify, if you can, and as we do ourselves. Elsewhere it is, as I said, Georgian or Gothic, and to the college trustee it is now the question "under which King, Bezonian?" Harvard, after swinging the circle of every possible architectural dogma and heresy, has settled down, as she should, to Georgian, as has Williams, and as have so many of the smaller and poorer preparatory schools and colleges, particularly in the South, but Yale, West Point, Pennsylvania, New York, Princeton, Bryn Mawr, Washington University, St. Louis, and Chicago, together with all the larger preparatory and Church schools, and the newer Roman Catholic institutions, are uncompromisingly Gothic of the type made immortal by Winchester, Eton, Oxford, and Cambridge.

Mr. Cram gave an exhaustive account of Princeton University, of which he is Supervising Architect. The title itself,

* Extracts from a paper read before the Royal Institute of British Architects, May 20th.

he said, will indicate at once one of the many points of divergence between the English and American systems, for he understood there is no university in the United Kingdom where one man is given almost complete authority over all matters of the choice of architects, supervision of their work both in design and execution, acceptance or rejection of gifts, and their placing, if accepted, the development of roads and paths, and the planting of trees and shrubs. Until recently such an office was unknown in America, but since Princeton took the lead some five or six years ago, others have followed rapidly, and the practice has now become established.

Points from Princeton.

In the new plan of Princeton, which shows the University as it now is, and indicates its future lines of development, there is seen a strong tendency towards the standard type. The dormitories are assuming quadrangular form, and in time may become full residential colleges, each with its common room and great hall, and, when times have still further changed, its chapel. In the beginning our dormitories were simply barracks, with living rooms opening off long halls, with remarkable results so far as order and discipline are concerned. Now the "entry" type is almost universal, the type that holds in England—the standard type of suites of a study and two bedrooms for two undergraduates, and a study and bedroom for each graduate student. In the former case each stairway is separated from the next by a party wall, unbroken except in the basement, to which all staircases descend, and here a general corridor gives access to groups of baths and toilets, and to the boxrooms, and to the other staircases in the quadrangle as well. In the newest of our buildings for graduate students every two suites have a private bath between. Notable is the magnificence of the gymnasiums. The mania for natural science is less dominant at Princeton than elsewhere, but two of the newest and most magnificent buildings are devoted the one to biology the other to physics.

A notable Gothic Renaissance amongst American colleges began with the new library at Princeton. John Stewardson and Walter Cope brought into being at Princeton, Bryn Mawr, and the University of Pennsylvania structures that are to the author singularly beautiful and inspiring, and they left their mark for all time on American architecture.

New Era in Scholastic Architecture.

About the same time an Englishman, Mr. Vaughan, sometime pupil of George Bodley, began the introduction of the same style into our great preparatory schools. His work at St. Paul's marked a new era in this category of scholastic architecture, and was continued later in more sumptuous fashion at Groton. My own firm has been following his leadership in the Convent School of St. Mary, at Peekskill, and the Taft School in Connecticut, while there are innumerable examples of the same sort of thing all over the country. It was really Cope and Stewardson's work at Princeton that set the pace, however, and so beautiful was it, so convincing as to the possibilities of adapting this perfect style to all modern scholastic requirements, that the University authorities passed a law that for the future every building erected at Princeton should follow the same general style. The altogether wonderful quadrangles of Holder and Hamilton Halls, by Messrs. Day Brothers and Klauder, of Philadel-

phia, marked for the author almost the highest point achieved in Collegiate Gothic in modern times. "When the great quads are completed we shall, I think, confront a masterpiece."

Turning to other American colleges, Mr. Cram dealt first with Columbia University, New York—the noblest type of the pure Classical idea. There is little else that is purely classical among American Universities, though Carrère and Hastings have built a most engagingly Parisian Alumnae Hall at Yale, the Naval Academy at Annapolis is strictly French, and the University of California is growing on scrupulously Beaux-Arts lines afar on the Pacific Coast. Georgian, however, has established itself as a determined rival of the "Oxford Mixture," and some of its products are not only logical and lovely, but genuinely scholastic as well. Harvard is conscientiously following this line, and so is Williams. In Virginia, also, we are slowly constructing a great college for women, while we are using the same style for another of our oldest and most famous "preparatory schools" at Exeter as well as at yet another girls' college, Wheaton, in Massachusetts. Georgian also, with rather quaint Roman elements, has been used by McKim, Mead, and White for the vast War College at Washington.

"Cope and Stewardson's Wonderful Work."

The University of Pennsylvania shows still more of Cope and Stewardson's wonderful work, though here it is couched in an extremely rich Elizabethan vernacular, and the style is handled in a magnificent and competent fashion. Here it is all red brick and yellow stone, and the same materials are used in Mr. Day's beautifully proportioned and very reserved Gymnasium. Bryn Mawr is again built of the wonderful stone that underlies all Pennsylvania and New Jersey, putting a premium on good architecture. Here in England all building stone is finely dressed, but in America we have adopted the practice of using "ledge stone" for our ashlar, our trimmings only being tooled. Fortunately, we have a wide variety of singularly beautiful stones, ranging in colour through all shades of grey, brown, purple, and tawny, easily obtained, inexpensive, and durable. In a way I think we gain a richness in colour and texture that is obtainable in no other way, while we also acquire something of that effect of age which is, after all, so essential a part of architecture.

Washington University, St. Louis, is later work of the form of Cope and Stewardson after the latter had died, and, good as it is, it shows the loss of the peculiar poetry that marked everything Stewardson touched. At Chicago University the first buildings were distributed without any regard to architectural effect, and Shepley, Rutan, and Coolidge, in taking over the work, have been badly handicapped. This is the most archaeological of the "college Gothic" in America, accurate, conservative, and reserved. Mr. Post's "College of the City of New York" is as poetical, fantastic, and imaginative as the other is austere and cautious.

The Three Real Things.

The author, in commenting upon several other examples of college buildings, deduced from his examples that good Gothic is encroaching steadily on the preserves of Classicist, Boulevardier, and Colonial, and this in spite of the fact that, with the single exception of Harvard, every one of

our schools of architecture, absolutely disregards every type and phase of Gothic, both in design and in theory. Having shown several views of the United States Military Academy at West Point, the author concluded: "We do, indeed, indulge in skeleton construction, and reinforced concrete and other structural expedients, and substitutes, but deep in our racial consciousness, as in that of all other Anglo-Saxon peoples, is the solid conviction that after all there are but three real things in the world—the home, the school, and the Church—and that when we are dealing with eternal verities honest and enduring construction is alone admissible. And it is to the same consciousness I think that we may attribute the very universal return to Gothic of some form for our churches and our colleges and our schools. After all, there have never been but three real styles of architecture in the West, noble in impulse, organic in structure, perfect in detail, and these three are: Greek, Byzantine, and Gothic; everything else is either a patois or a form of slang. Greek and Byzantine are in essence alien to our blood and temper, and Gothic alone remains."

The photographs and drawings brought over by Mr. Cram to illustrate his paper will be on view in the Galleries of the Royal Institute until Saturday, June 1.

EARLY IRON MANUFACTURE.

At the meeting of the Iron and Steel Institute at which Sir Robert Hadfield, F.R.S., read the paper on the ancient origin of iron and steel from which extracts were given in last week's issue (p. 541), Sir Hugh Bell presented some "Notes on a Bloom of Roman Iron found at Corstopitum (Corbridge)." He said that according to an examination made by Dr. J. E. Stead the bloom measured 39 in. between the extremities of the metallic portion; its diameter at the widest part was 7 in. by 8 in., and at the smallest part 5 in. by 4½ in. It weighed 3 cwt. 8 lb., but as it was thickly coated with rust, and contained oxidised slag in the hollow upper part, also much imprisoned slag, the net weight of the metallic part was probably not more than 3 cwt. On close examination of the external surface there was evidence that the bloom had been built up and welded in sections as suggested by Professor Louis, as the terminations of some of the laps could be easily seen. In general terms, slabs approximately lenticular in section were employed. After the smaller end was made, the piece at this stage probably had a similar appearance and shape to the upper end of the bloom in the condition in which it was found in the furnace with projecting taper pieces. After forming the foundation piece, two slabs must have been inserted *vis-à-vis* and the mass then heated to welding temperature, after which it was removed and welded by hammering, but by what kind of implements there was no evidence. Step by step this process was repeated until the bloom of the size and dimensions as described was obtained, *plus*, of course, the portion which has been removed by subsequent rusting.

In a "Note on Some Remains of Early Iron Manufacture in Staffordshire," Professor Thomas Turner referred to lumps of iron, locally known as "ham bones," which were found round the site of an old forge at Little Aston. On analysis the sulphur content was ascertained to be ex-

tremely high, and the next most characteristic point was the very low carbon and silicon. The material was certainly not cast-iron. It might be assumed that the original "ham bones" were never really fluid, but that they were accumulations at the bottom of a furnace employed for the production or manufacture of wrought iron. Their shape clearly suggested that they were produced in the small hearth or bottom of a primitive furnace, as the projecting piece corresponded with a tapping or flowing hole. Apparently as soon as the accumulation at the bottom of the furnace reached the height of the tap hole, the process was suspended. The iron, rich in sulphur, was doubtless more fluid than the rest of the material; it was thus separated and collected in the bottom of the furnace.

Professor Henry Louis, speaking on the papers presented by Sir Hugh Bell, Sir Robert Hadfield, and Professor Turner, said that there was no direct evidence that the Romans knew cast iron, except as produced by accidental means. Even civilised nations were using direct-made wrought iron until about the year 1880, at which time it was being made direct from the ore in the Lake Champlain district of the United States. Whether the old Indian workers were acquainted with cementation was rather a doubtful point, but they did know how to make a steely iron, which gave results somewhat similar to cementation. He had had three micro-photographs taken from a small piece of direct made Indian iron, of about a quarter inch square, and they brought out the great difference in the carbon content, which was one of the most notable characteristics of direct made iron. The specimen shown by Sir Hugh Bell was no doubt made direct from the ore, probably from the ores in the coal measure of the district.

"THE GATE OF INDIA."

The visit to India of their majesties King George and Queen Mary aroused an enthusiasm among the people that has never been equalled. The genuineness of the sentiment may be measured both by the hearty participation of the nation in the festivals held on the occasion and the splendid character of the decorations that were displayed both in capital towns and in the interior. Bombay lived fully up to its motto, "*Urbs Prima in Indis*," in the matter of decoration for the occasion, and, among all the special structures erected by the Reception Committee, the most noteworthy was the temporary building raised on the Apollo Bunder, where their majesties landed in India. The design is by Mr. G. Wittet, consulting architect to the Government of Bombay, and is in the Indo-Saracenic style peculiar to the Presidency.

The building consisted of a light frame of wood covered with matchboard and finished with a coating of calico and lime-wash. The domes were framed in wood, covered with basket-work of split bamboo, and finished with a mixture of plaster and chopped coir fibre, which stood for four months in good condition, and even passed unscathed through a smart shower in December. This style of construction is found among the domes of some of the Cairo mosques that are framed in wood, lathed inside and out, and plastered with the mixture used for covering the flat roofs of the city. When properly done, this kind of dome lasts for many generations. The rainfall of Cairo averages about three-quarters of an inch per annum. The white surface of the building at the Apollo Bunder (or Bandar) was relieved by gilt mouldings and plaques, and illuminated at night by lines of red electric

lamps. Thousands of people came every evening to see the beautiful effect of the lighting. In the day-time the intense light of the Indian sun sufficed to give to the homely material all the effect of the purest marble. Their majesties expressed so much admiration for the structure that a movement was set on foot to reproduce it in permanent form in white marble. Estimates were made amounting to £52,228, of which the Government of India proposes to pay £19,998, and Sir Jacob Sassoon has contributed an equal sum, leaving £12,232 to be furnished by the local government and municipal and other corporations.

No position could be better chosen for the Gate of India. The site has been the place of landing and embarking of India's most distinguished men for many generations. It gives upon a harbour that is six miles wide, and beyond the opposite shore is the mountain range that forms the watershed of India.

Although India possesses ample deposits of marble, they are so far from the coast that the cost per cubic foot is greater in Bombay for the marble of Jabalpure than that of Italy.

An official notice to the Press states that the building must provide ample accommodation for any future ceremonies which may take place at the Bunder. Its general effect when seen from the sea must also be considered, and this will probably result in an increase in the height. A garden is also contemplated, which will adjoin the "Gate" and add to its attractiveness. The Gate of India will probably be built of armoured concrete, faced with marble, which will reduce the cost, decrease the weight, and take nothing from its artistic effect. The illustration is by Mr. Shushunkar Narayan, photographer to the School of Art, Bombay.

"THE GATE OF INDIA," ON THE APOLLO BUNDER, BOMBAY. G. WITTET, CONSULTING ARCHITECT TO THE GOVERNMENT OF BOMBAY.

ENQUIRIES ANSWERED.

Reversible Fireplace.

We have received a number of communications from readers in answer to the enquiry published under the above heading on page 479 of our issue for May 8th. It appears that an apparatus such as described by our original correspondent is manufactured both by the Falkirk Iron Company, of Craven House, Kingsway, London, and Messrs. J. and R. Corker, Ltd., of Rotherham. On request, these firms would doubtless be pleased to supply further information. A Swansea correspondent sends the illustration which we reproduce herewith of a reversible fire-

place for which the patent was taken out some years ago. It is not known whether this contrivance is on the market.

Question of Building Line.

SUBSCRIBER (Halifax) writes: "Most surveyors, I believe, in determining a building line, take a straight line between the buildings upon each side of a vacant plot. It was recently proposed to erect a new building between two others—one being set back 9 ft. and the other 35 ft. from the street front. The building line for the new structure had been settled at a distance of 20 ft. back, thus avoiding any encroachment upon the building line as customarily fixed. The clerk to the local sanitary authority, however, advised that, under Section 3 of the Public Health (Building in Streets) Act, 1888, the authority could insist upon the new building being set back to the level of the deeper building, namely, to a distance of 35 ft. Kindly give your opinion as to whether this can be legally enforced."

—Assuming that this building is not in a new street, with a building line set out a certain number of feet back, I am of opinion that the proposal to build 20 ft. back is entirely in order, and that the local authority have no powers to insist on the 35 ft. they apparently desire, as Section 3 of the 1888 Act reads: "It shall not be lawful in any Urban District, without the written consent of the Urban Authority, to erect or bring forward any house or building in any street, or any part of such house or building, beyond the front main wall of the house or building on either side thereof in the same street, nor to build any addition to any house or building beyond the front main wall of the house or building on either side of the same."

F. S. I.

Builder's Business on Co-operative Lines.

A CORRESPONDENT writes: "Kindly give your opinion as to the practicability of working a builder's business on co-operative lines."

—It is apparently practicable, because, according to statistics published by the Board of Trade, the number of co-opera-

tive Production Societies engaged in building as associations of consumers at the end of the year 1908 in the United Kingdom was sixty-eight, employing 1,569 persons and doing a sales turnover of £272,495. These were retail societies. In addition there were two wholesale co-operative societies engaged in building, employing 1,131 persons and with a sales turnover of £271,226. For the year 1909 the corresponding figures were seventy-three societies, employing 1,391 persons, turnover being £234,264 for the retail building. In the wholesale branch there were two societies, employing 1,154 persons and turning over £259,201.

In addition to the above there were Associations of Workers in the building trade representing 107 associations, combined into six co-operative production societies, employing, in 1908, 211 persons and turning over £92,828, and in 1909 employing 186 persons and turning over £105,994. No detailed information is given as to profits earned, but in 1908 fifteen societies earned a profit of £3,609 on a turnover of £98,828, and in 1909 twenty societies earned £704 profit on a turnover of £105,994. As those two years are generally regarded as years of great depression in this trade, the results may be really more favourable than they look, as many building concerns made losses at that time and some large failures resulted.

A. G. W.

Weather-Boarded Cottage Construction.

B. P. (London) writes: "Can you refer me to any publication in which the details of construction of a weather-boarded, wood-studded cottage are explained? I want particularly to know how the external angles should be made. Kindly name examples of such work, old and new, near London."

—Full particulars and details of frame-houses are given in "Building Construction and Superintendence," Part II., by F. E. Kidder, published by W. T. Comstock, of New York, and obtainable from B. T. Batsford, High Holborn, price 20s. In the best work a solid post would be used on each external angle—say a 4 in. x 4 in. where the ordinary sheds were 4 in. x 2 in.—but in simple or unimportant work the angles may be made up of two 4 in. x 2 in. as

sketch. A vertical board is nailed up each angle as shown, against which the weather-boarding stops with a butt joint. Such boards are usually about 4 in. wide and sufficiently thick to stop the weather-boarding without projection. As to examples, there are numerous old buildings in Essex showing this construction. Modern examples near London are scarce owing to by-law restrictions. Mr. F. Troup built a very successful weather-boarded cottage at Letchworth in the first exhibition there, and this, presumably, is still to be seen.

G.

Insulating Material for Hollow Wall.

AILSA writes: "What is the best insulating material with which to pack either a hollow wall or a framed partition for the purpose of forming an effective cold-storage chamber? I have used slag wool packed tightly with fairly satisfactory results, but would like to know of something better."

—Short of actual brine circulation, I know of no more effective insulation than slag wool. That material should not, however, be "packed tightly." It should be compactly filled into the spaces by light hand pressure. If rammed tight the fibres are broken and the air expelled, reducing the insulating power.

G.

Dry-rot in a Country House.

G. and B. (Hereford), write: "We have had to inspect and report recently on an outbreak of what was supposed to be dry-rot in a large country house. As a result of our examination, we found one piece of rotten skirting in a first-floor room. This was fixed against an outside wall exposed to the south-west, and the decay extended for about six feet along the skirting. We send you samples of this skirting, and may say it has been in this state for years, though the rot has not spread to the floor-boarding, joists, or other woodwork in the vicinity. Another instance has been found in one of the wine cellars, where the woodwork was extremely wet and rotten; but the symptoms of dry-rot, such as fungus and a peculiar smell, were not present."

—The portion of rotten skirting submitted does not present features which conclusively determine whether the decay was due to dry-rot—that is, to the action of the fungus *Merulius lacrymans*—or to wet-rot, but there is a strong probability that it was due to the former. The position of origin, against an exposed outside wall behind the skirting, whose varnished surface prevents the wood from drying out into the room, is just such a situation as would assist the germination of dry-rot spore. The character of the decayed wood assists the same conclusion. There is, however, no sign of the fungus; but that is hardly to be expected since the skirting is said to have been in its present state for many years; and, at the most, it can originally only have been a slight attack. It does not follow that dry-rot fungus once started is bound to spread. Unfortunately, it very often does, and that, too, with the most disastrous consequences; but the fungus is amenable to the laws of plant growth, and will not continue to flourish if the surroundings cease to be favourable. It is equally certain that, if it has once died, it cannot start again when the damp surroundings return. But it may, during its life, have formed a fructification, and in that case left many tens of thousands of spores behind it, each one of which is capable of continuing the work of destruction. In the present case it appears likely that the fungus has been of limited growth and then died out, and that either the wall has since become dry or that there has been no second spore to produce a successor. The circumstances, however, are probably still congenial to the growth of any spore that may chance that way, and it would be better to leave the exhausted wood in position than to place new wood to form the food of a future growth, unless the damp condition of the wall is remedied. This may be effected by washing the exterior with three coats of Szerelmey's stone-preserving fluid, applied when the wall is as dry as it is likely to

be, or by adopting Musgrave's K system to dry the wall first before the fluid is applied. In any case, every portion of the decayed wood should be removed and burned, and no wood plugs should be used for fixing the new skirting. Alternatively, the skirting may be worked in cement, and after it has thoroughly seasoned it may be painted to match the rest of the skirting. A wash of antiseptic on the wall, which should be allowed to dry out again before the new wood skirting is fixed, would be a wise precaution. B.

THE "PERMUTIT" SYSTEM OF WATER SOFTENING.*

BY DR. JOHN F. MEYER.

As far back as 1756 the natural zeolites are first described in the "Transactions" of the Academy of Sciences at Stockholm; but it was not until 1850 that Theodor Way, consulting chemist to the Royal Agricultural Society in London, established the fact that the zeolites placed in contact with salt solutions were capable of absorbing the bases contained in the dissolved salts, at the same time yielding up into solution the bases which they themselves contained. The author repeated one of Way's experiments:—In this small glass filter, he said, you see a layer of natural zeolites; for convenience I took fuller's-earth. I will pass through it a water of 10 deg. hardness, and as you will see from the test I now make the hardness of the

filtered water has been reduced. The following reaction took place: The bases contained in the hard water, calcium and magnesium, have been absorbed by the zeolites, and the latter have given up their own bases (sodium) to the water. This experiment explains to a certain degree why a soft water of perhaps 7 deg. is very often found at a depth of, say, 500 ft., while at a depth of 100 ft. the hardness of the water out of the same borehole is 50 deg. The explanation is that rain water passing through a stratum of limestone, and thus becoming hard, afterwards passes through a layer of these natural zeolites, whose softening action you saw just now.

Dr. Gans, Professor at the Mining Academy of Berlin, and president of the Laboratory of Geonomy at the Berlin University, made a thoroughly scientific research of the natural zeolites, classified them, and published the constitution formulæ. Ultimately Professor Gans succeeded in producing zeolites artificially, and took out a patent to manufacture artificial zeolites on a commercial scale in the year 1906. He named his artificial zeolites "Permutit" from the Latin "permutare," to exchange. The author here conducted a series of experiments, disclosing the whole Permutit process for water softening down to 0 deg., and the procedure of regeneration, and exhibited two drawings showing different types of a Permutit water-softening plant—gravity and pressure.

The permutited water effects the largest possible saving in those industries or places where soap is used. Permutited water is further an excellent water for drinking.

A further phase of the Permutit process is the manganese permutit, manufactured by precipitating heptoxide of manganese

on a permutit by permanganate of potassium. If I pass a water which contains iron or manganese through this filter all the iron and manganese salts will be oxidised and kept back in the permutit. The regeneration of the filter takes place by using a solution of permanganate of potassium. These manganese permutit filters work excellently in those cases where every trace of iron and manganese has to be taken out of the water, and further to eliminate organic matter. Another application of the manganese permutit filters is to sterilise waters which contain harmful germs. Since these plants can be worked at a high rate of filtration, the initial and working costs are very small, the working costs being about $\frac{1}{8}$ d. per 1,000 gallons of water treated.

DETAILS OLD AND NEW—XLII.

Woodwork in Pembroke College Chapel, Cambridge.

The present chapel of Pembroke College was built by Bishop Wren after his release from the Tower, the architect being his nephew, Sir Christopher Wren. Most of the woodwork is the same that was originally set up, including the carved cartouches, swags, and capitals, which are executed in some variety of oak. There is a range of stalls on either side, and two returning on each side of the door below the organ screen at the west end (of which the view on p. 559 is a detail). From the building accounts it appears that the woodwork was done by "Cornelius Austine and Richard Billopps and William his sonne of Camebridge, Joyners." The chapel was dedicated on September 21st, 1664.

THE QUANTITY SURVEYORS' ASSOCIATION.

Annual Dinner.

The annual dinner of the Quantity Surveyors' Association was held on May 20th in the Connaught Rooms, Great Queen Street, W.C., the President, Mr. C. W. Ball, M.S.A., being in the chair. Among those present were the Right Hon. the Lord Mayor of Leeds; Messrs. George Corderoy, F.S.I.; A. A. Hudson, K.C.; H. P. Bulnois, M.I.C.E.; Alfred W. S. Cross, M.A., F.R.I.B.A.; S. Chatfeild Clarke, F.S.I.; T. Sidney Vickery; H. M. Hodgson, F.S.I.; G. L. Brighton, F.S.I.; Henry Northcroft, F.S.I.; H. H. Bartlett; H. A. Bartlett; W. R. Hood, F.S.I.; F. G. Rice; Dudley Bartlett; James Wright; Henry Riley; Walter Lawrence; J. Carmichael; T. Costigan; T. P. Figgis, F.R.I.B.A.; Alan E. Munby, F.R.I.B.A.; A. Needham Wilson, F.R.I.B.A.; T. J. Careless; Arthur G. Cross, F.S.I., and many others.

At the conclusion of the dinner, the toast of "The King" having been observed,

The Right Hon. the Lord Mayor of Leeds (Mr. William Nicholson), proposing the toast of "The Quantity Surveyors' Association," said the absolute necessity for such an Association as theirs was manifest if they were to get a living wage and keep their heads above water. Unfortunately, in the North of England, it was a prevalent practice of the architects to take off their own quantities. He said without hesitation that this was not right. In building, the indispensable units were a good builder, a skilled architect, and an experienced quantity surveyor. The County Councils were sweating the quantity surveyor, but the municipalities, he understood, were not even employing him, a state of affairs which it had been his constant endeavour to correct. Having drawn a distinction between the functions of the architect and the engineer, the speaker said that, on behalf of the contractors, he would say they had to look forward to dearer prices. What with current legislation, strikes, the increased cost of labour and its lessened degree of production, the prices of to-day would not pay for the work. The old rates would do no longer; they would have to be revised. In conclusion, he wished every success to the Quantity Surveyors' Association.

The President, in reply, said that when the Council did him the honour of electing him president he suggested three things which he wanted to be brought about during his year of office. The first was a conversazione. This was duly discussed, but the proposition was lost. The second was a visit of the Association as a body to his own town of Portsmouth. Circulars were sent out to members; but the response was disappointing, and the proposal fell through. The third was the establishment of the benevolent fund upon a satisfactory basis. This had been quite successful, for instead of the £46 for which he had asked £78 had been subscribed in response to his circular letter. With regard to the Association, the principal event of the year had been the creation of a new Associate class of member. Members of this class had to be twenty-two years of age, and had to pass an examination giving evidence of training, experience, and capacity, and although this arrangement had only just come into force they had admitted many new Associates who, in due course, would become full members.

They had also passed a new by-law by which it became an offence for a member to do work within a value of £70,000 at less than the schedule scale of charges. They had not issued a third pamphlet on the standardisation of measurement, but a sub-committee had been formed to discuss the matter with the Surveyors' Institution. The matter was being thoroughly considered, and it would be premature to say more than that. They now possessed a presidential badge, and he had the honour of being the first president to wear it. The names on the bars which already adorned it were: W. Lawrence, A. J. Gate, W. R. Hood, Arnold E. Harris, H. T. Chidgey, and Chatfeild Clarke. Presidents, he continued, might come and go, but their honorary secretary, like the brook, went on for ever. They valued the services of Mr. Cross very highly. Without him he did not believe their society would go on and flourish as it did at the present time. There had been a considerable increase

in membership, and several of the leading surveyors, he was glad to say, were joining their society.

Mr. H. M. Hodgson, F.S.I., proposing the toast of "The Architects," said the more they knew of architects and the more of them they knew the better they were pleased. The mere surveyor needed some temerity to speak on architecture in the presence of architects. If surveyors had any preference in architecture it was for a severe, formal, Classic style. The "restless" style, which was often referred to in architectural circles, seemed to the quantity surveyor to be pure cussedness; it doubled his work without increasing his fees. The three R's of the quantity surveyor would be regularity, rectangularity, and repetition. The design which looked most simple on plan always worked out best; they put this down to a merciful dispensation of Providence and not to an attempt of the architect to save the quantity surveyor's labour.

DETAIL OF WOODWORK IN PEMBROKE COLLEGE CHAPEL, CAMBRIDGE.

Mr. A. W. S. Cross, M.A., F.R.I.B.A., responding in the absence of Mr. J. Dixon Butler, said that, having been called upon unexpectedly, he was quite unprepared with a speech, and he was in the position of having to clothe non-existent ideas in words which failed to come to his mind. He hoped to see the extension of their Society's sphere of influence. The quantity surveyor was indispensable to the architect, especially when the builder's bill of extras loomed large on the horizon. There was undoubtedly a real bond of sympathy between the two bodies, and he hoped it would be maintained.

Mr. Henry Riley proposed the toast of "The Contractors." They had, he said, to work with a host of specialists, and their task was becoming increasingly difficult. No other industry was so likely to be badly affected by strikes.

Mr. H. Arthur Bartlett, President of the Institute of Builders, in reply, referred to the threatened strike in the

VICISSITUDES OF A STATUE.

Alfred Gilbert's bronze statue of Queen Victoria at Winchester, unveiled recently by Princess Henry of Battenberg, has seen strange vicissitudes. In 1887 the late Mr. W. Ingham Whitaker, of Pylewell Park, Lymington, was High Sheriff of Hampshire, and to commemorate the first Jubilee he offered to present to the county a statue of Queen Victoria. His desire was that it should be in marble and be placed in the ancient Great Hall of the Castle, where Kings of England had sat in state, where Parliament had met, and where historic trials had been held. The Court of Quarter Sessions accepted the offer, but declined to allow the statue to be placed in the Hall. A site on Castle Hill outside the Hall was offered and accepted, and the material of the statue was changed from marble to bronze. Gilbert produced a design which at once attracted the attention

against the position in the Abbey Gardens. They pointed out that the statue was more suited for an indoor light than out of doors, and recommended that it should be placed in the Castle Hall, beneath the Round Table of King Arthur. Mr. W. Ingham Whitaker, the son of the donor, then came forward and offered to take such steps as were necessary to complete the statue, provided it were placed in the Castle Hall, as intended by his father and the sculptor. The offer was accepted and orders were given for the removal of the statue from the Abbey Gardens, where it had been located for fourteen years. About a month ago the finishing touches were put to the work, the last being to affix to the medallions on the socle minute nude figures bearing a scroll with the name "Victoria." These were recently designed by Mr. Gilbert, who has worked with enthusiasm on the finishing of his masterpiece, which has thus come triumphantly through its extraordinary vicissitudes.

HIS MAJESTY'S THEATRE, MANCHESTER: SCULPTURED PANEL (23 FT. IN LENGTH) FOR FACADE.
HORACE FARQUHARSON AND RICHARDSON AND GILL, ARCHITECTS.

London building trades. They were meeting the men, he said, and trying to find a middle course, so as to avoid the strike and its consequent interference with trade. Nowadays, he continued, the man who could take the highest figure off cost price before sending in a tender was the one who got the job. To illustrate the extent of specialisation, Mr. Bartlett mentioned a case where even the excavations had been given out to a specialist. Architects always demanded the very best of everything; he had never seen a bill of quantities asking for second-quality materials. These did exist, but he had never seen them specified; he wondered what became of them.

Mr. S. Chatfield Clarke proposed the toast of "The Visitors," to which Mr. George Corderoy replied.

Mr. A. A. Hudson, K.C., then proposed the health of Mr. Arthur G. Cross. Mr. Cross made a brief reply.

New Park for Bury St. Edmunds.

The Bury St. Edmunds Town Council has agreed to accept an offer of the historic Abbey grounds of thirteen acres for a public park and recreation ground from the Marquess of Bristol on a twenty-one years' lease at £100 per annum.

of the world of art, the statue was set up in its place, and the Duchess of Argyll (then Marchioness of Lorne) unveiled it. Subsequently the idea prevailed that it was in the way, and it was thereupon removed, placed in a corner of the Castle yard, and covered with a tarpaulin. Mr. Gilbert was naturally indignant at the treatment of his work, and declined to finish it.

In 1893 the late Earl of Northbrook, then Lord Lieutenant of the county, arranged to place it in the Abbey Gardens. The statue was placed in a position facing north, so that the sun never shone on its face; thus it always appeared a black mass and the exquisite detail of the work was lost. The effect of the atmosphere on the bronze turned it to a greenish-black colour, and altogether its fate did not seem to have improved. Later, when the Alfred Milenary was celebrated, the gigantic statue of King Alfred, on its lofty granite monolith, was placed only a few yards away, and the contiguity of the great statue had the effect of dwarfing that of Queen Victoria and giving it a squat appearance. A proposal was then put forward by the late Rev. G. A. Seymour to erect a canopy over the statue. The President of the Royal Academy and Mr. T. G. Jackson, R.A., however, reported against this proposal and

HIS MAJESTY'S THEATRE, MANCHESTER.

The accompanying illustrations show the detail of the front elevation of His Majesty's Theatre, Manchester, which building is now in course of erection and will be completed in the course of the next four months. From the drawing reproduced it will be admitted that the design is an admirable one, and the architects (Messrs. Horace Farquharson and Richardson and Gill) are to be congratulated on what promises to be the most scholarly and dignified theatre erected in this country within the last half-century. The sculptured panel illustrated on this page has been modelled by Messrs. John Tanner and Sons, of Westminster, from the architects' design and represents "The Dawn of the Heroic Age." It is being carried out, like the rest of the front, in "Ferrocon" (artificial stone). Some excellent plaster-work has been designed for the interior by the architects and executed by Messrs. John Tanner and Sons, the detail being Neo-Grec in character with abundance of vigour: in which particular it is notable, when compared with the detail usually found in theatres.

(By Our Press Gallery Representative.)

Office of Works Architects.

Mr. Snowden, in the House of Commons last week, asked Mr. Wedgwood Benn, as representing the First Commissioner of Works, if it was his intention to see his undertaking of December 7th last in that House, that the desires of all the class termed architectural assistants should be ascertained with a view to placing them upon the establishment list, carried into effect.

Mr. Wedgwood Benn referred Mr. Snowden to the reply he gave on the 6th inst. in answer to a similar question. (The reply has been published in THE ARCHITECTS' AND BUILDERS' JOURNAL.)

Mr. Snowden observed that the reply was no answer to his question. He proceeded to ask another question in the following terms:—Whether, up to and including the year 1903, the class termed architectural assistants, formerly senior draughtsmen, engaged in his Department performed all the professional duties, and with the ability now expected, of the assistant architects, consisting of the charge of one or more contracts with the preparation of all the design and construction plans directly under the architects; or what class did perform those duties at this period, seeing that the total number of the class termed assistant architects numbered only eight, who were engaged in nearly every instance upon official routine, and that the amount of the architectural work in the Department was within 80 per cent. of the total amount at present, but that the total number now was forty-six; whether he was prepared to aver that the professional abilities exhibited in the exercise of these duties by the architectural assistants were not equal to those exhibited now by the class termed assistant architects; and why, since that period, numbers of junior draughtsmen had been established to take over these duties formerly satisfactorily performed, thus causing grave dissatisfaction to the architectural assistants.

Mr. Wedgwood Benn said the answer to the first part of the question was in the negative. In reply to the second part, the honourable member was mistaken in his figures. There were thirty-one assistant architects in 1903. There were now forty-nine. Of temporary men there were about 120 in 1903, and there were about 216 now. As regards the third point, the architectural assistants had, in the majority of cases, had the opportunity of competing for permanent posts, and had either not availed themselves of it or had failed. As regards the last point the establishment had since 1902 been recruited by competitive examination of members of the unestablished staff.

Mr. Snowden asked whether the titles of the two classes engaged in the Department, architectural assistants and assistant architects, were upon professional grounds one and the same; whether the professional diplomas held by both classes were equally distributed, the number of associates and licentiates of the Royal Institute of British Architects in the architectural assistants' class being twenty out of a total of fifty, and that of the assistant architect class eighteen out of a total of forty-six; whether the services rendered by both these classes were one and the same; and whether both these classes were equally certificated, the one class holding the technical certificate of the Commissioners of the Board of Works and the other class that of the Com-

missioners of the Civil Service; and would he therefore see that the Civil Service rule of equal reward for equal class conditions was in this case observed by establishment and remuneration?

Mr. Wedgwood Benn said there were nineteen associates of the Royal Institute of British Architects among the assistant architects and eleven among the architectural assistants. There were also two licentiates among the former and twelve among the latter. The associates and licentiates were, of course, not upon the same footing. The answer to the third part of the question was in the negative, and to the fourth, that the two certificates were not in any way equivalent.

Mr. Snowden asked if the hon. member would take the necessary steps to prevent the present established architects' staff termed assistant architects from being increased by the present method by members of the junior unestablished staff, termed draughtsmen, by examination or otherwise, until the services of every member of the present certificated senior unestablished staff, termed architectural assistants, had been fully utilised by establishment and remuneration as those in a similar professional position, classed as assistant architects.

Mr. Wedgwood Benn said the First Commissioner regretted that he was unable to give the undertaking required.

Mr. Snowden asked whether the designs and the necessary constructive documents constituting the basis of the building contracts formerly in the sole charge of the class termed architectural assistants directly under the chief of the branch were being now taken from them, thus reducing their position to a subordinate one, and handed over to a class junior to them in age and service and termed assistant architects of the second class; whether the resulting friction occasioned by this action was hampering the progress of the work of the Department; and would the hon. member give instructions that the original express conditions of service in this and other respects of the architectural assistants be reverted to.

Mr. Wedgwood Benn said the points raised had been practically dealt with in previous questions. The growth of work had rendered necessary the increase of the permanent staff in order to relieve the architects by devolving a certain amount of the work on the assistant architects. No instance of friction hampering the progress of the work of the Department had been brought to the notice of the First Commissioner, and no instructions were needed for any change in the current procedure.

Dublin Post Office.

Mr. H. Samuel, Postmaster-General, has informed Mr. Field that proposals involving the rehousing of several departments of the Post Office at Dublin have been under consideration for some time, but they are not yet sufficiently advanced to enable the Postmaster-General to form an estimate of the probable cost or to fix any date for beginning the works.

New Bridges Across the Thames at Reading.

The Reading Town Council decided last week to erect two bridges over the Thames between Reading and the newly incorporated area of Caversham. It is estimated that the cost of the schemes will be £65,000. One bridge is to replace the existing Caversham Bridge, and towards the other a Caversham ratepayer has contributed £5,000.

ILLUMINATING ENGINEERING
SOCIETY.

In the report of council for the session November, 1911, to May, 1912, of this society, it is stated that during the past year the society has been fortunate in extending its influence in many directions. Meetings have been devoted mainly to securing the co-operation of the general public, and many subjects of great interest have been discussed. A marked feature of the past session has also been the consolidation of the international position of the society, which is now coming to be regarded as the European centre of information on matters connected with illumination.

The development of public interest in illumination and the increased output of literature on the subject have again been most remarkable. It is particularly satisfactory to observe the direct interest taken by the daily Press in the practical consequences of insufficient illumination. This has taken the form of frequent references to such matters as street lighting, the influence of illumination in mines on the eye-sight of miners, the lighting of the House of Commons, etc.

The number of members of the society now exceeds 340—an increase of seventy over the number at the corresponding period of last year. Architects, surveyors, etc., make up five per cent of the membership.

The society has added to its list of vice-presidents the names of Sir William Abney, D.Sc., F.R.S., C.B., Prof. A. F. Kenelly, and Prof. Elihu Thomson, and has also nominated its President (Prof. S. P. Thompson, D.Sc., F.R.S.) one of the honorary life members for the present year.

The joint committee—on which representatives of the Institutions of Gas and Electrical Engineers, the Association of County and Municipal Engineers, and the Illuminating Engineering Society are nominated—is still engaged on its task of preparing a draft specification for street lighting. A considerable number of meetings have been held, and much valuable data collected, and it is anticipated that its findings will be available shortly.

The joint committees on school and library lighting decided upon at the conclusion of the discussions of the society on these subjects at the commencement of last year have now been constituted. Representatives of the Library Association, the Association of Medical Officers in Schools, the Association of Technical Institutions, the Association of Teachers in Technical Institutions, and the London Teachers' Association have been appointed, and are taking part in the proceedings. Several meetings have already been held, and the committees are preparing some suggestions which, it is hoped, will prove of considerable use to those concerned with the lighting of schools and libraries. In addition, it is proposed that these committees will act as a permanent centre for information on these subjects.

It will be remembered that at the International Electrical Congress in Turin, last September, the following resolution was passed: "That this Congress deems it desirable that an International Commission should be appointed in order to study all systems of lighting and technical problems in connection therewith; and, having been informed that the Illuminating Engineering Society of London has the intention of forming such a Commission and of putting itself in touch with the other existing

national and international photometric committees, approves their taking the initiative in this respect." A resolution was also passed unanimously by the Electro-technical Commission affirming "that the National Committees should co-operate with the Illuminating Engineering Societies in their respective countries in studying the question of symbols, nomenclature, and other matters relating to illumination."

By this resolution, it is observed, the support from the electrical industry throughout the world has been secured, and it is hoped to obtain similar international encouragement from the gas industry.

CORRESPONDENCE.

The Editors disclaim all responsibility for the statements made or opinions expressed by correspondents. Correspondents are asked to be brief, and to write on one side only of the paper.

The R.I.B.A. Elections.

To the Editor of the ARCHITECTS' AND BUILDERS' JOURNAL.

SIR,—If any justification were required for the circular issued by the Institute Members' Club, the letter signed "A Fellow of the Institute" in your last issue would supply it. This gentleman would have the R.I.B.A. deliberately stultify itself, and he has no notion whatever of the effect such a proceeding would have in the provinces, where our brethren are anxiously awaiting some tangible outcome of the policy to which the Institute is solemnly pledged. If those who suffer from unfair competition looked with some alarm on the House List issued by the Council, they are more than justified in taking steps to safeguard themselves against those who, like your correspondent, are oblivious of definite obligations. I imagine anti-Registrationists will hardly thank "A Fellow" for his injudicious letter.

AN ASSOCIATE OF THE INSTITUTE.

Mystic Board of Trade Returns.

To the Editor of the ARCHITECTS' AND BUILDERS' JOURNAL.

SIR,—Traders are asking how it is that, according to the Board of Trade returns, the trade of this country is going up by leaps and bounds. Each month you see larger returns published, and people are mystified, especially those in the building trade, which trade has been declining ever since the Boer War commenced.

Recently we have been fixing up a Canadian agency for "Pudlo," which makes cement waterproof, and of which I am the sole maker. I find that there is a preference given to English-made goods. For instance, in Canada there is a duty of 25 per cent. on English-made goods, whilst on foreign-made goods the duty is 35 per cent. I find that the Germans and many other foreigners send produce to England, and then re-ship it to our Colonies in order to gain the preferential tariff, which in some cases is rather a considerable amount. Now, as this preferential tariff is of comparatively recent origin, it is to be expected we shall continuously import and export larger quantities of all kinds of goods.

I thought this matter might interest your readers, and I am sure it will interest many hundreds of my customers, who have many times expressed their wonderment at trade returns showing such prosperity while our trade is so very slack.

J. H. KERNER-GREENWOOD.

King's Lynn.

NEWS ITEMS.

A Business Announcement.

Messrs. Vulcanite, Ltd., have acquired the business of Messrs. Watson and Co., Brentford, whose "Reliance" lead and bitumen dampcourse, and other bitumen and asphalte specialities, will in future be manufactured at Messrs. Vulcanite's own works. All inquiries and orders should henceforth be sent direct to Messrs. Vulcanite, Ltd., at their offices—118, Cannon Street, London, E.C.; Laganvale, Belfast; or Westinghouse Road, Trafford Park, Manchester.

Tattershall Castle Fireplaces Recovered.

With the assistance of a number of generous lovers of antiquities in the County of Lincoln and elsewhere, Earl Curzon of Kedleston has recovered the famous carved stone fireplaces, dating from the fifteenth century, which were taken out of Tattershall Castle last year. The work of restoring the castle and its surroundings to their former condition, so far as it can properly be done, has already been commenced by Lord Curzon and as soon as this work is sufficiently advanced the fireplaces will be restored to their original position. It is estimated that the restoration at Tattershall will not be completed until next year, when Lord Curzon proposes to place it on view to the public.

Sewer Gas Consumed in Lamp Standards.

An apparatus for the consumption of sewer gas, invented by Mr. William Rodger, burgh engineer, Dunoon, and fitted to one of the public lamps in the burgh, has in the interior of the lamp a combustion chamber in the form of a two-part cone. The lower portion of the cone is carried through the base of the lamp head and connected to the upper part of the lamp standard, the upper part of the cone being designed to fit the lower portion and also the upper portion of the lamp head. In the interior of the upper portion of the cone there is fitted a baffle plate, and below this there is a Bunsen or other suitable burner fed from the main gas supply through a by-pass, so that the Bunsen is kept lighted even when the supply to the illuminating burners is cut off. The sewer gas is led from the sewer to the lamp standard, and passes upward into the cone, being burned partly below and partly above the baffle plate.

New Municipal Works.

The Local Government Board has decided to hold, or has recently held, as the respective dates indicate, inquiries into proposed expenditure by public bodies as follows:—Water supply works.—Bideford Borough Council, £19,300 (May 29th); sewerage, sewage disposal, drainage.—Lower Babington Urban District Council, £1,150 (May 28th); St. Helens Borough Council, £18,000 and £9,000 (May 31st); Ongar Rural District Council, no amount stated (June 4th); street improvements, recreation grounds, etc.—Hendon Urban District Council, £2,562 (May 30th); Tiverton Borough Council, £3,350 (May 30th); Brighouse Borough Council, £4,125 (May 31st); Devonport Borough Council, £4,559 (including quay walls) (May 31st). Various.—Kettering Urban District Council, £2,600, for art gallery and £2,100 for corn market (May 28th); West Riding County Council, £32,000 for county hall extension at Wakefield (May 29th); Congleton Borough Council, £1,700 for gas under-

taking (May 30th); Heywood Borough Council, £11,000 for ditto (May 31st); Keighley Borough Council, £6,576 for electricity undertaking (May 29th); York City Council, £9,700, for ditto (May 30th); Heywood Borough Council, £2,500 for ditto (May 31st); Brighouse Borough Council, £3,000 for ditto (May 31st).

Rural Housing.

At the annual meeting of the Rural Co-partnership Housing Association, which was held at 53, Grosvenor Street, W., last week, Lord Henry Bentinck, M.P., who presided, said that the wages of the agricultural labourer were so small and the housing accommodation so bad that there was no wonder he preferred to go into the towns, and so accentuated labour troubles. Co-partnership had done a wonderful amount of good in connection with town planning, and they were thankful that somewhat similar principles were now being carried out on intelligent lines in rural areas. Mr. J. St. Loe Strachey (editor of the "Spectator") suggested that many of the difficulties in the provision of cheap and good houses for rural areas would be overcome if by-laws were abolished and in their place it was arranged that certificates of fitness for habitation should be given. People ought to be able to experiment in the building of cheap houses, but in most districts the by-laws prevented this being done.

OUR PLATE.

The Temple of Ipramboul.

The fine drawing by Mr. A. C. Conrade, reproduced as the Centre Plate in this issue, is a restoration of the entrance hall of the rock-cut Temple of Ipramboul, Egypt. This entrance hall has eight colossal figures, 33 ft. high, standing against square piers at the sides. In the distance is seen the inner sanctuary, with three seated gods (there is a fourth, not visible from this standpoint). The figures on the side walls wear the head-dress known as the "corn-measure," and carry the crook and scourge as emblems of power. The ceiling is covered with paintings.

R.I.B.A. DESIGNS FOR FINAL EXAMINATION.

The Board of Architectural Education of the Royal Institute of British Architects announce that the designs submitted by the following students who are qualifying for the Final Examination have been approved:—

Subject I. (a).—(A large Monument to commemorate King Alfred's refounding of London.) H. A. Dod, Hal Harper, Ernest Prestwich, H. C. Bradshaw.

Subject I. (b).—(A Terrace of Five Houses.) R. F. Dodd, Walter E. Woodin, S. Stevenson Jones, W. Harding Thompson.

Subject II. (a).—(A large Monument to an Explorer.) H. Lidbetter, R. S. Dixon, F. O. Laurence, F. A. Broadhead, R. Duckett, E. F. Bothwell, C. M. McLachlan, W. E. Woodin, R. A. Barber, J. O. Cheadle.

Subject II. (b).—(A Cloister with external entrance gateway or tower to a collegiate building.) H. A. Dod, H. C. Bradshaw, E. Prestwich.

Supplement to THE ARCHITECTS' AND BUILDERS' JOURNAL, Wednesday, May 29th, 1912.

THE ENTRANCE HALL OF THE TEMPLE OF IPRAMBOUL, EGYPT: A RESTORATION BY A. C. CONRADE.

A WHITE LEAD COMBINE.

During the past few months a great change has taken place with regard to the white lead industry.

Until September, 1911, this industry was in a very unsatisfactory condition, owing to several causes, but more especially to keen and unrestricted competition among British manufacturers, and, to a less degree, among manufacturers on the Continent. The price of what is known as dry white lead stood, on the average, at a figure which left little or no margin of profit on the year's working. It is a product in which a considerable amount of speculation takes place, or did take place, and the price varied very considerably. In the middle of last year the price was 16 10s. to £17 per ton, the exact figure depending upon the particular brand and quality of the manufactured article.

For years previously there had been delirious discussions as to the possibility of some kind of combination and it appears that last autumn the inclinations of white lead manufacturers both in this country and in the rest of Europe and in the United States were brought to a focus; so that ultimately the basis of an agreement was drawn up, and in due course submitted to every manufacturer throughout the world. When the setting up of an effective combination was found to be imminent, it naturally had an effect on market prices, and dry white lead has risen from about £18 to £22 or £23 per ton. The representatives of the manufacturers have been elected in each country, and the Convention which has met in London has been a thoroughly international and comprehensive character. The actual agreement was only signed a few days ago, and this is the first authorised statement on the subject. It has been suggested that as a consequence of the formation of this Convention and agreement it will be quite easy to raise the price of the product another 5 per ton or more at the pleasure of the central authority. But there are two reasons at least why this is unlikely to happen. One is that if the price of white lead were substantially increased it would tend to check consumption, and so hinder

HOUSE AT EDGBASTON, BIRMINGHAM.
BUCKLAND AND HAYWOOD-FARMER, ARCHITECTS.

the progress of the industry. Another reason is that, while the efforts made to discover a substitute capable of producing paint of satisfactory quality have been up to now fruitless, chemists are constantly working at the problem, and it is quite possible that something may be discovered which at least for many purposes might get into general use as a substitute for white lead, particularly for indoor work.

Altogether distinct from the Convention referred to, which is concerned with dry white lead, there is a combination among the manufacturers of ground white lead, which is the finished article as supplied for the mixing of paints and other purposes. This organisation will, we understand, act in harmony with the white-lead Convention.—(Extracts from the "Financier and Bullionist.")

BANKRUPTCY PROCEEDINGS.

Mr. Ernest A. Runtz.

On May 21st Mr. Registrar Brougham held the public examination of Mr. Ernest A. Runtz, architect and surveyor, of Victoria Street, Westminster, who was adjudged bankrupt, upon his own petition, on April 3rd. The statement of affairs showed lia-

bilities £8,388, of which £3,684 was expected to rank for dividend, and assets valued at £505. Mr. Runtz stated that he was formerly a partner in a firm of auctioneers and surveyors carrying on business in Moorgate Street. In 1888 he became a director of the Birkbeck Bank, and in 1897 began business on his own account as an auctioneer, surveyor, and valuer, his profits from that business between 1897 and 1906 having varied from £2,300 to £3,000 a year. The Official Receiver: "In 1908 did you resign your directorship of the Birkbeck Bank owing to your disapproval of the policy of the board?"—"Yes, and other causes." By that resignation he lost an income of £600 a year. Since 1906 his business had continuously declined owing to the stability of property in this country being affected by recent legislation. In 1907 and 1909 respectively two large companies, which were paying him fees, failed. His fees from one of these companies for the eleven years before its failure had averaged £600 a year, and he lost over £1,000 a year in fees by the failure of both companies. In 1909 his business resulted in a loss of about £406, in 1910 a profit of £840, and in 1911 a loss of £683. His wife's money had been invested in property in the East End of London, which formerly

produced an income of £800 a year, but the value of the property had been affected by alien pauper immigration, and since 1910 had not produced a penny. He filed his petition as a result of a judgment for £600 being recovered against him, and but for that judgment he believed that he could have pulled through. The examination was ordered to be concluded.

Mr. J. C. Hill.

At Bankruptcy Buildings last week Mr. G. W. Chapman, Official Receiver, presided at the statutory first meeting of creditors held under the receiving order made against Mr. John C. Hill, who had carried on business as a builder and brick manufacturer at Archway Road, Holloway, and at Ponder's End, Great Bentley, and Old Fletton, near Peterborough. The debtor had not yet lodged a statement of his affairs, but the claims of the unsecured creditors were estimated at between £80,000 and £100,000, and there were fully-secured liabilities amounting to about £1,000,000. Apart from equities of redemption in properties, the realisation of which the debtor thought was uncertain, the only assets disclosed were valued at about £1,120. The Official Receiver reported that, according to the debtor's statements, since 1887 he had traded as a brick manufacturer as well as a builder, and both businesses had been very successful, and would have so continued had it not been for the great depreciation of his various properties and the practical stoppage of the speculative building trade. Depression in the brick-making trade followed, and the debtor said that these circumstances had arisen in consequence of the land clauses of the Finance Act. He got into difficulties with the mortgagees of his properties, and owing to the depression was unable to re-mortgage. In 1909 he sold the brick business at Fletton to a company. He attributed his failure to depreciation of his freehold and leasehold properties during the last five years and to the depression in the brick trade, both caused by recent legislation in regard to land and houses. The creditors appointed Mr. W. B. Peat, chartered accountant, as trustee, to administer the estate in bankruptcy.

SOCIETY OF ARCHITECTS.

At the meeting of the Society of Architects held on May 9th (Mr. Percy B. Tubbs, F.R.I.B.A., vice-president, in the chair) the following were elected:—

AS MEMBERS.

R. H. Blackburn (Bradford).
H. Y. Boreham (London, E.C.).
B. Chaikin (London, N.E.).
D. C. Davies (Merthyr Tydfil).
W. W. Diggle (Hampstead).
T. Dowson (Sandsend).
B. J. Emery (Birmingham).
E. Hale (Birmingham).
J. R. Hall (Sheffield).
A. C. Harbottle (Exeter).
E. J. Harbottle (Exeter).
H. A. Lane (Mansfield).
H. V. Milles-Diamond (Chandlers Ford).
J. E. S. Pritchard (Kidderminster).
N. Richley (Durham).
W. F. Sargisson (Ancou, Peru).
W. Southall (Retford).
G. A. Sutherland (Wick).
H. G. Walker (Whitby).
J. E. Webb (Nottingham).

AS STUDENTS.

J. V. Bowring (Eastwood).
R. B. Craize (London, S.W.).
F. F. Hayward (Johannesburg).
A. J. Johnson (East Dulwich).
F. R. Priest (London, S.W.).
T. Rayson (Oxford).

COMPETITIONS.

Church Buildings at Mansfield and at Bedford.

The limited competition recently held with respect to the erection of Nottingham Road U.M. church, schools, institute, and caretaker's house, Mansfield, has been settled in favour of Messrs. George Baines and Son, 5, Clements Inn, Strand, W.C., and the first section of the scheme, estimated to cost about £4,700, is to be at once proceeded with. The same firm were placed first in the competition for Russell Park Baptist Chapel, Bedford, and have been appointed architects for the scheme.

Proposed New Golf Club House, Bolton.

The limited competition held for the above building, in which Mr. Arthur J. Hope acted as assessor, has been decided in favour of the design submitted by Mr. R. Hermon Crook, of Bolton.

The Whiteley Homes.

At a meeting of the trustees of the Whiteley Homes at Fox Oak, Burhill, near Hersham, held last week, the schemes submitted in the limited competition for plans for laying out the site for the homes (in future to be known as "Whiteley Park") were considered, the design submitted by Mr. R. Frank Atkinson, F.R.I.B.A., being adopted. Mr. Walter Cave, F.R.I.B.A., was the assessor.

Society of Architects' Travelling Studentship, 1912.

Four designs were submitted in competition for the above, and that sent in by Mr. F. Morrall-Maddox, of Burton-on-Trent, has been placed first. The subject set was a design for a town hall on a sloping corner site, to cost £30,000. Mr. Morrall-Maddox also gained the Society's Architectural Scholarship in 1907. He served his articles with Mr. George Dickens-Lewis, M.S.A., of Shrewsbury.

PICTURE EXHIBITIONS.

The Fine Art Society.

At the gallery of this Society is to be seen a collection of early Chinese paintings, dating from the tenth to the seventeenth century. These are all decorative paintings, long and narrow, vertical strips of material, showing decorative designs of foliage and birds, many of them of great beauty in a decorative sense. Of course, it is when they come to deal with human figures that they comparatively fail, though one figure of "The God of War" shows a good deal of power. In another room is a collection of water-colours of scenes in Spain and the Canary Isles, by Miss Ella Du Cane. Miss Du Cane has her own way of handling water-colours, the flowers and foliage, which play a great part in the pictures, being executed in small touches of very strong and decided colour, which glitter on the paper by contrast with the very light treatment of the skies; the effect is very brilliant and gives the drawings a strongly marked character of their own.

Architecture, where introduced into the subjects is always very well treated. It is interesting to see a collection of drawings which have a decided style and treatment of their own, and are not just like other good water-colour drawings.

Messrs. Tooth and Sons' Gallery.

At this gallery there is a collection of pastels, mostly landscapes, but with a few interiors, by Mr. Lhermitte, an artist to whose style of landscape painting pastel is peculiarly suited; in fact, his oil paintings are rather pastellist in character. These are admirable examples of the free and broad treatment of landscape, or landscape and buildings combined; the large one, called "La Pilgrimage," is a very fine picture, though the action of the group of figures does not quite explain itself in relation to the title. Among the smaller pictures "Le Vieux Jardin," "Laveuse, le Matin," and "Moulin à Eau," are especially good.

MANCHESTER, SALFORD, AND DISTRICT BUILDING TRADES EMPLOYERS' ASSOCIATION.

As recorded in last week's issue of the JOURNAL, Mr. George Macfarlane, J.P., who has held every office it is possible for anyone to hold in the National Federation of Building Trades Employers, from chairman of the smallest local committee to the Presidency of the National Federation, was the recipient of a testimonial at the annual general meeting of the Manchester, Salford, and District Building Trades Employers' Association, held at National Buildings, St. Mary's Parsonage, Manchester, on May 16. The testimonial, which comprised an illuminated address, a cabinet of cutlery (110 pieces), a silver tea service and tray, fruit stands, etc., which had been subscribed for by the members and friends of the local affiliated associations and Federation, was presented by Mr. Henry Matthews, J.P.

Mr. Councillor James Higson, J.P. (the newly-elected president of the association), Mr. James Storrs, J.P., and Councillor S. Smethurst, J.P., joined Mr. Matthews in eulogising the splendid services that Mr. Macfarlane had rendered to the building industry throughout the country.

Mr. Macfarlane, who spoke with visible emotion, said he felt sure that he had done nothing to warrant such an astonishing manifestation of kindness. He appreciated very highly the genuine goodwill and kindly disposition which had prompted the bestowal of such a token of their affection and esteem, and he expressed the hope that after he had gone his children would prize the gifts as fitting heirlooms, and that they would always remember, when they used them, the honour conferred upon their father by his fellow-workers and fellow-tradesmen, who had shown that even rivals in business could be kindly disposed and generous to each other. He felt that his services for the trade had been considerably magnified, but at the same time he hoped that every member would cultivate that spirit of mutual assistance for the benefit of the trade which had always been his object. He should always look back upon that day as being the red-letter day of his life, and he assured the members that as long as he was able he should continue to work in their interests and for the welfare of the association.

Concluding Notice.

HAVING already reviewed the works of the Academicians and the illustrations of public buildings and of church architecture, we may now conclude by noticing some of the exhibits not included in those categories.

Professor Pite exhibits a drawing of his frontispiece to the Piccadilly end of the Burlington Arcade, which is now familiar to all Londoners. It answers its purpose very well; to tack anything very original to the end of such an old-fashioned avenue as the Arcade would hardly have been in keeping with the situation. We next turn to two drawings by Mr. Lutyens, both executed in a very effective though rather sketchy manner in water-colour. The "Art Gallery for Johannesburg" seems, as far as architectural expression goes, exactly the thing for a rather small art gallery; it is obviously an art gallery, and could be nothing else. It is a long, low building, with a columned portico in the centre, the wings being solid wall with a recess for sculpture in the centre of each. An outlying building on each side has a high hipped roof, with two windows and a sculpture recess between them. What function these fulfil is not apparent, but the whole forms a very agreeable architectural composition. Mr. Lutyens's larger drawing, "Headquarters, Theosophical Society, Tavistock Square," is one of the best things in the room. A complete plan is given, showing that there is a quadrangle entered under an archway, above which rises a tower, worked first into an octagonal stage and then into a circular cupola; the entrance is through a tunnel vault in a rusticated basement. The two wings which advance in front, on each side of the entrance, are very simply treated, with square-headed windows, of which one in the centre of the second floor is accentuated by a pediment, and higher up a similar pedimented window breaks the line of the attic. The whole forms an expressive and well-balanced piece of architecture.

Mr. Martin's "New Hall, Wilton Terrace," is a piece of interior Classic architecture, of which the ceiling design, as far as shown, seems to be the most interesting part. Mr. Pearson exhibits a large line drawing of "New Wing, Sidney Sussex College, Cambridge" (no plan), in what may be called collegiate style. The large oriel window, however, from its manner of treatment, rather disturbs the repose which should characterise this type of architecture. Professor Reilly exhibits an interior of the "Gilmour Hall" in the Students' Club of Liverpool University. The walls show a Doric order and entablature, with what might be called an attic above the cornice, which at the end of the room is pierced with windows. The flat ceiling is heavily coffered all round, leaving a large panel in the centre, which appears to have a ceiling painting on it. A Doric order seems rather too heavy a feature for an interior of this kind.

The "Accepted Design for Stockport Police Court," by Messrs. Halliday and Paterson (no plan), might be a

bank, though it will do for a police court. It is a low Classic building, with strongly marked horizontal lines. In the centre rise higher blocks, which probably represent the upper part of the courts. Following the order of hanging, we next notice something rather unusual, in the shape of a country bank standing in the middle of a garden—"Bank at Matlock," by Messrs. Langham and Parker (no plan). Apparently this is really the bank manager's residence, with the bank attached to it as a one-storey building at one end; the distinction between the bank entrance and the residence entrance is well marked. Mr. E. White's "Garden to a house at Adelsnäs" is a small pencil sketch looking up the central vista of the garden, with a circular opening and fountain in the foreground; in the middle distance are seen symmetrical stone flights of steps arranged on curved lines. It looks like a very good and effective bit of ornamental garden planning, formal without being too formal. Mr. Warren's "Radcliffe Infirmary, Oxford: New Admission and Research Wing," is a kind of building of which a plan ought to have been given. All one can see is a perspective view of a very plain stone building, with which there is no fault to find, but its architectural virtues are rather negative.

Messrs. Weymouth and Easton exhibit a large perspective of alterations and additions to "Belvidere Fort, Windsor Great Park," for the King. From the colouring of the plan we suppose that the additions are the set of rooms which form a kind of tail to the older portion of the plan. This seems to be an old-fashioned piece of battlemented Gothic. The whole makes a good picture, and the plan seems to be well arranged so as not to interfere with the effect of the existing buildings. Mr. Prentice exhibits three drawings of houses in that exceedingly neat and finished line drawing in which his buildings are always illustrated; but no plan of any of these houses is given, and it is difficult to say anything about them except that they are all very neat examples of domestic Gothic, with mullioned windows, excellent as drawings, but rather deficient in any marked character. There is character enough in Mr. Palmer Jones's "House at El-Assasif, near Luxor." This represents the employment of indigenous architectural style by an English architect. The house appears to stand in a waste of sand hills, three domed blocks in the centre and at the two ends, connected by long, low-recessed blocks, with an arcaded loggia in front. The basement is of battered rubble walling, above which are plain masses of grey walling, without even a moulding at the top, pierced with a few small windows. This is, at all events, a drawing one cannot help looking at. A plan is added.

Mr. Oliver Hill's "Swimming Pool in a Garden, Berkshire," is an interesting pencil drawing, with a plan added. The swimming pool and a long grass lawn lie parallel, with a wide flagged walk between them. On one side of the pool the balustrade takes a semicircular sweep, with a flight of steps following the curve. At the top end of the pool there is also a somewhat similar alcove with steps. This is a good piece of open-air garden architecture. Messrs. White and Webb's "Marden Park, Woldenham," a water-colour drawing hung very high, is

another piece of open-air garden architecture, showing three turfed terraces rising in successive slopes, with flights of stone steps in the centre, leading down to a circular fountain basin. Mr. Crickmer's "Group of Houses, Letchworth," done on tinted paper, with the plastered upper storey of the houses put on in white, is of interest from the plan of the block of houses and the garden in front of them filling the triangle between a meeting of two roads, the house at each end of the block being canted on plan so as to face parallel with the road.

Mr. Walter Brierley's "Sion Hill, Thirsk," is an important exhibit, illustrated by a rather unusual plan. A long narrow "outer hall" runs the long way of the house, out of which opens the hall, with dining-room at one end and boudoir at the other, the hall apparently serving the purpose of drawing-room. The outer hall leads at one end to a small square "garden hall," out of which a garden door opens, and the smoking-room is contiguous to this. A compass added to the plan (as it always should be on a house plan) serves to show that the right aspect of the various rooms has been carefully considered. It is a red-brick house, relieved by white window sashes, and with fine stone gate piers showing in the foreground. Mr. Ball's "East and West Fronts of Furze Hill, Willersley," are two very pleasant little pencil perspectives, illustrating unfortunately the want of a plan, for the perspectives show both elevations, back to back, with the end portions canted forward at an angle, but how does the plan work out to these lines? Messrs. Unsworth, Son, and Triggs's "Ashford Chace" is a pretty house, with a plan showing some unusual and effective treatment. Mr. Maule's "Kelling Hall, Norfolk," a small but very carefully executed bird's-eye view, is worth attention. The plan shows some original points, especially the boudoir and drawing-room forming two projections at an oblique angle at one end of the house, with a columned loggia formed from the triangular space between them. The whole plan is interesting, and seems to have been carefully considered, but we do not understand what is the end erection, with a slightly concave front, outside of the servants' hall. Mr. Tilden's "Porth-en-Alls, Cornwall" (no plan), is a fine pen-line drawing of a house of somewhat striking and unusual character. It looks as if intended to have the special character of a seaside house for an exposed situation, with the basement wall battering and the windows with massive unmoulded mullions. A kind of pyramid of steps goes up to the entrance arcade, beneath which is a large doorway, with a heavily moulded segmental arch over it—perhaps a boat-house. The same architect exhibits a small sketch of "Cottage, Porth-en-Alls," which appears to be a cottage on a curved plan and with very little window—perhaps the windows are on the other side, but it is a bit of local character in building.

In the "House in Smith Square" (no plan), which is a house with the entrance door in the internal angle of the square, Messrs. Blow and Billerey have adopted a simple architectural treatment in keeping with the general style of this quarter of London, grouping the windows vertically, with a cornice over the middle window; plain brick wall surface between the groups of windows. Mr. T. E. Cooper's "Proposed Public Library, Homerton," is really a detail elevation of the entrance, with a detail plan and also a general plan of the building. This is a very well-considered piece of Classic detail in a severe style. In the view of the "Weights and Measures Offices, Whitecross Street," by Mr. Sydney Perks, we come to a piece of very characteristic and picturesque building, on which the architect may be congratulated. The ground floor shows large round-arched windows in plain brickwork, above which are two storeys of small flat-headed windows divided by white strips of cemented or roughcast wall, producing, in a very inexpensive manner, a kind of pilaster effect. The centre feature has coupled brick pilasters carrying a segmental pediment. A small plan is added. This is a very good and interesting example of the treatment of a plain building for business purposes. "Business Pre-

mises, Duke Street, St. James's," by Messrs. Harris and Moodie, is also a piece of building possessing some character, having a stone rusticated basement with arched windows, and above this columned and pedimented windows in stone, which stand out against an expanse of brickwork; the large stone cornice at the top is stopped against large consoles, which seems a better way than merely returning it on itself. Mr. Waterhouse's two buildings for two assurance companies, the "Prudential," at Grimsby, and the "Atlas," at Birmingham, illustrated in two very good water-colour drawings, show the same general idea in the design; in each there is a high ground storey with a very large arched window in the centre—that, we suppose, is the office part of the building—and above this commences an orthodox Classic treatment with a pilaster Order. Of the two, we prefer the Birmingham building.

In a very large perspective drawing Mr. Henry Tanner shows "Oxford Circus" as we suppose he intends to rebuild it so as to get the circus effect again, with an Order and cornices at the same level, which in the way of dignity of appearance will certainly be an improvement on its present condition, though it is very difficult to realise the effect of a circus at all when four such wide streets cut into it. One quadrant of this design is already erected; if the rest follow soon it will certainly be an important street improvement to this part of London.

There is not much decorative work to speak of in the Architectural Room this year. Mr. Leslie Wilkinson's "Wrought-Iron Gates for an Estate in Russia" is a good piece of design on the generally accepted lines of the best English work of the kind, but does not differ materially from a good many other designs, ancient and modern. Mr. Palmer Jones's "Mausoleum at Brookwood" is another good piece of design of its class, of rather German type, which is saying nothing in its dispraise, for the German architects of the day are almost at their best in the designing of sepulchral monuments. The architect has depended for its effect mainly on the arrangement of mass and outline in a design of sober masonic character, with hardly any ornament; and the work is very effectively shown in a water-colour drawing. Of the various coloured drawings of stained-glass windows which fill up small spaces amid the architectural drawings there is little to be said: they are mostly of familiar conventional types. Mr. Guy Miller's little drawing of a stained-glass window representing "Industry" is a remarkable bit of colour, but it is a perspective representation of an interior, which is a mistake in stained glass. The most original suggestion for a window is another by Mr. Miller, "Design for a Library Window," illustrating Tennyson's poem, "The Lady of Shalott." In the lower portion, which is mostly white glass, the figure of Lancelot on his charger is slightly indicated in colour, and in the upper part of the window is a circle in stronger colour, indicating the Lady at work on her "web." There is fine decorative effect in this little design.

It is, however, a very poor way of exhibiting stained glass design to hang a few small water-colour drawings of windows, in which only the intended colours can be shown in flat tints, while the real effect of stained glass cannot be realised at all. At an "Academy of Arts" in the true and full sense, there should be an arrangement for the exhibition of some actual stained glass, to be seen by transmitted light. But the Royal Academy is practically little more, in its exhibitions, than an Academy of painting, and that it is so is to a great extent the fault of the public, which cares more for pictures than for any other form of art; and the exhibitions are arranged accordingly, since the main object is to please the public and render the exhibitions popular. This is not a satisfactory state of affairs. The Academy ought to aim at educating public taste in art, rather than merely giving the public what it wants.

The Proposed Chair of Town Planning.

IT is proposed to establish a Professorship of Town Planning at the London University. It is rather a question whether Town Planning is not getting promoted into the position of being a kind of special mystery without quite sufficient reason. The considerations which govern good town planning are, in fact, what every good architect ought to understand as part of his art; it is a part of architecture, which men like Wren and Barry, for example, thoroughly understood without regarding it as an art separate from any other branch of architecture. There has been a great deal of attention specially called to the subject during the last few years, but the requirements of good town planning, æsthetic and practical, are no more than what ought to be a part of the perception of any really able architect. In a chair of architecture town planning ought to be supposed to be naturally and necessarily included. To raise it to the dignity of a kind of special and separate profession seems rather likely to end in producing a series of *doctrinaire* theories as to the right way to do it, which would not be by any means universally applicable. An architect who cannot plan a town or a new suburb well is not likely to plan anything else well.

A Drawing of the Pantheon.

WE illustrate on this page a measured drawing of one bay of the Pantheon, Rome, by Mr. Ernest Prestwich, who is the first student of the School of Architecture, Liverpool University, to spend a year at the British School at Rome after taking his degree. Mr. Prestwich's main work, apart from small studies such as this, has been a careful measured survey and restoration of Sulla's monumental summer residence, temple, and gardens at Palestrina. These drawings, now nearly finished, are on a scale approximating to the restorations by the French Prix de Rome students at the Villa Medici, and will form the first English example of this sort of work which has been done since the days of Wood and Robert Adam.

The Conference on Street Name Plates.

THE Art Committee of the Institute of Architects recently took up the consideration of the extremely unsatisfactory condition of street name-plates in London in regard to their design, their variety of form and style, and their absence at many points where they ought to be fixed, and some correspondence took place between the Committee and the various Borough Councils of London on the subject. Some few of the

MEASURED DRAWING OF ONE BAY OF THE PANTHEON, ROME, BY ERNEST PRESTWICH
(School of Architecture, Liverpool).

Councils were recalcitrant and seemed inclined to take the line that they understood their own business best, but from the majority there was a sympathetic response, and ultimately a small conference was held a few days ago between a number of members of the Institute of Architects and representatives of a majority of the Borough Councils. The main points to be considered in connection with the subject are the artistic character of the name-plates, the material to be used, and the question whether they should be different for each borough, or whether there should be a uniform design for the whole of London. As far as the lettering is concerned, what is important is that it should be easily legible and that the lettering should be of good artistic character. For this latter object, of course, it is not necessary, nor even desirable, that letters of any unusual form should be adopted. The more simple they are the better, provided that their lines are good. The best system would seem to be that of letters in relief on a dark ground. One advantage of having them in relief is that when they become weather-stained and require renewal this can be done by merely painting them afresh, a mode of renewal which can be done by anyone who can handle a paint-brush. The London and North-Western Railway Company found this out long ago and employ raised letters which can be painted on by anyone, whereas letters painted on a flat ground require a practised sign-writer to renew them.

The question of a uniform design for the whole of London will probably raise some differences of opinion. Some of the Borough Councils wish that each of them should have its own distinctive name-plate, so that the character of the plate will be an indication which borough the street belongs to. That seems to us to be a mistake. One objection to it is that in some cases the borough boundary goes down the centre of a street, so that in that case there would be a different character of name-plate on the two sides of the street. A more important objection is that the desire to have a distinctive style of lettering for each borough would increase the difficulty of selecting a simple form of lettering; there would be a temptation to elaborate different forms of letter in order to make these distinctions. But the most important consideration is that it is much more for the convenience of the public to have a universal form of plate adopted for the whole of London. And another point is involved in this, viz., the importance of having name-plates placed at the corners of all streets, without exception. Some of the Borough Councils, it appears, are afraid that this will involve them in an inordinate expense. They have no right to take that into consideration. Their duty to the public is to provide every passenger with the means of knowing what street he is in the moment he enters it. At present there are many cases where a man has to go some distance along a street before he finds its name up. This is quite different in Paris. At whatever street-corner you arrive in Paris there you will see the street name up, because the Paris municipality do these things in a thorough and systematic manner. What is done in Paris can be done in London, and ought to be done. Some interesting and very practical observations on the subject are supplied in another part of the present issue by a contributor, who illustrates some of his points with a few snap-shots of typical London and suburban name-plates.

Architects Signing Their Buildings.

A WRITER in the "Manchester Guardian" has a rather amusing paragraph commenting on the fact that a building has been advertised for sale with the recommendation that it was "designed by the late E. M. Barrie, R.A.," and, after thus mis-spelling the architect's name, goes on with the statement that he was mainly remembered as the son of his father, "the designer of the Houses of Parliament." The great architect who designed the Houses of Parliament was Sir Charles Barry and it is rather melancholy to find

that a prominent newspaper does not even know how to spell his name; and his son, E. M. Barry, was an architect of great ability, who would have had a claim to be remembered as such in any case. As to the matter of architects signing their names on their buildings, as a painter signs his pictures and a sculptor generally cuts his name somewhere on the pedestal, we quite agree with the writer in question that it would be very desirable that architects should do so; it would, at all events, serve to remind the public that there are such persons as architects and that buildings do not grow of themselves.

The Cambridge Slade Professor on Art Study.

THE inaugural lecture delivered by Mr. Prior, the new Slade Professor of Fine Art at Cambridge, was of a much more practical type than such addresses sometimes are. Mr. Prior naturally regards architecture as his special province in carrying on the work of the Professorial chair, and on that subject he has definite opinions and expresses them in a clear and decisive manner. He pointed out that there were two classes of persons concerned with art, more especially in regard to what University teaching can do. There is the man who purchases art and the man who produces art; and the University has two faculties which it can train, that of the public and that of the artist. But we are disposed to think that the first is really the proper work for a university. As regards the teaching of the artist, Mr. Prior dwelt strongly (as we should have expected that he would) on the importance of craft knowledge of an art—and we may suppose that he was still thinking mainly of the art of architecture—not merely a book knowledge. Of course, he is quite right—specially right in regard to architecture; but can we think of Cambridge University becoming to any extent a technical school of art training? That is what must be meant, if it means anything, and we can hardly conceive that to be the object of a university. The primary object of a university is a high mental training, what is called a "liberal education." It can hardly be said that technical education comes properly into that programme and we should think that the man who is in especial want of technical training would be able to get it much more effectually somewhere else than at a university. The real business of a university professorship of art is to educate its students in the understanding of art—to teach them to realise what art is and to distinguish good art from bad. Mr. Prior made a strong point about this in remarking how many clergymen were educated at Cambridge and went from the University into positions in which they might have the whole custody and preservation of an important work of ancient architecture in their hands; and, as he quite truly said, many clergymen were very deficient in the degree of knowledge of and interest in architecture which would enable them rightly to treat and preserve the buildings under their charge. But is architecture the only art? How many Englishmen who have received a University education really know the difference between a good picture and a bad one? How many educated Englishmen, in the ordinary acceptance of the word education, care anything at all about sculpture? How few there are the sculptors know feelingly, for your educated Englishman, who may have taken a brilliant degree, comes perhaps to occupy an important position in the Government, but has never learned the value of art, or that it is something worth spending encouragement and money upon. That is what the University ought to teach him and that is what a Professorship of Fine Art in a University is really for—to ensure that men going through their University career should at least have the opportunity of learning something about art as part of their study, instead of their acquirements being confined to literature or higher mathematics. What we want especially in England is an enlightened public opinion on art. We have plenty of able artists, but they do not get sufficient encouragement, and University education in art should be one of the best means of developing that enlightened opinion.

THE CAPE DUTCH HOUSE.

THE beginning of European architecture in South Africa was made by Johan van Riebeeck, who in 1652 went to the Cape as the accredited agent of the Dutch East India Company, and built there a little wooden fort wherein to take shelter against the aggressive Hottentots. To him and to his successors, Simon and Adrian van der Stel, with their Dutch passion for stately avenues and broad spaces, must be credited the foundation of an excellent tradition in town planning, of which the influence is still observable in the cities of South Africa.

"When it is realised," says a scholarly writer in a recent issue of "The African Architect," "that a certain phase of architecture is the outcome of social and geographical conditions, it is easy to ascertain why the work of the early settlers possessed such distinct individuality and character. It required a great personality like Simon van der Stel, who in the face of tremendous opposition and continual fault-finding on the part of the Seventeen—the name by which the Dutch East India Company was known in Holland—centred his ideal of life in homes of quiet dignity and beauty amidst orderly plantations of avenues and groves. In future years, when the thoughts of the people are turned more decisively to the founders of the South African nation, they will discover that Van der Stel's part in it bore no mean resemblance in its influence upon the art forms of the country to that of Brunelleschi in Italy during the fifteenth century. The development of the architecture of these early settlers, who were in a position to be eclectic, must prove as absorbing to the student of architecture concerned with the formation of style as it is to the archæologist."

The writer shows that, having the choice of two styles—Dutch and Asiatic—they adopted neither, but formed a style of their own, drawing from both sources those features which best suited their needs. The resultant blend between East and West may be traced, for instance, in the narrow and delicate louvred screens which form such a charming feature in dividing the inner from the outer hall in the old homesteads of the Cape Peninsula. Rather curiously, they never adopted the covered stoep of the East, preferring, as a shelter from the sun, an open pergola or trellis, creeper-covered.

The law of local materials was to a great extent responsible for some of the most characteristic features of the early work, and to it is due the plain plastered walls and the long low line of snug warm thatch with which most of the country houses were roofed. In Capetown itself the prevalent heavy winds and the risk of a fire at a later date compelled the adoption of a flat plastered roof. The walls were built of bricks or rubble and plastered. The bricks were made by the settlers, who had at their command a large number of slaves imported from Madagascar. Wherever the brickwork was exposed, and this occurs in the steps and stoeps of the more pretentious homes, the bricks were imported from Holland, and were of a small yellow pattern, well-burned, known as "klompjes." The woodwork was almost invariably of teak, used in generous proportions, the furniture being occasionally embellished with ebony and ivory, brought by the returning vessels from the company's possessions in India. The carving which is used in rare but essential features of the houses was done by a few skilled workmen who migrated with the Colonists, amongst them the sculptor Anton Anrijt, who already enjoyed a considerable reputation in his own country. The greatest appeal that these houses make is their absolute simplicity; indeed, the *motif* of the whole may be said to be governed entirely by their human needs. They rely for their charm upon one of the most important essentials in all satisfactory architecture, that of good proportion.

The Castle at Cape Town.

The most celebrated work, and at the same time the greatest achievement, of these early Dutchmen was the

building of their castle with its moat. Its most striking feature is the entrance gateway, built with the small imported Dutch bricks. It is flanked on either side by a couple of pilasters with a frieze and pediment, all of hard green stone. The design, though simple, is good. The frieze contains six coats of arms of the cities interested in the company's trade—Amsterdam, Rotterdam, Delft, Zeeland, Hoorn, and Euckhuysen. Over the pilasters is the monogram of the company, whilst in the pediment are the arms of Holland. Above the entrance is an octagonal turret with a cupola, executed in the same small bricks, sheltering a fine bronze bell, bearing the inscription:—

"Benedicat Tena Dominum Laudet et super exaltetur in caecula Claudierenime Facet Amstoledam in anno 1697." The main walls are faced externally with local stone, and the plan of the fort is pentagonal. It was designed by the famous military engineer, Vauban. The inner courtyard contains the rooms and offices which originally served as the Governor's residence. The entrance portico to these is perhaps one of the most beautiful architectural features still remaining of old Cape Colony. The handsome doors have one of those

THE CASTLE GATEWAY, CAPETOWN.

wonderfully-carved fanlights, almost unique in the Cape Peninsula. The importance of this building in the history of the country's architecture will the more easily be realised when it is remembered that it was set down upon savage shores 6,000 miles away from European civilisation, built of the best material, and with architectural enrichments such as subsequent workmen have never surpassed.

"Groote Constantia."

To turn now to their domestic architecture. The first large country house in the colony was "Groote Constantia," built by Governor Simon van der Stel, who chose the site for his own farm in 1685, and spent his declining years there in peace. It is a far cry to those early days, but Constantia hands down to the modern wine farmer a reputation which his own products have not yet secured. Since the early days of the Huguenots at the Cape of Good Hope the farm has been famed for its wines. It is interesting to recall that it furnished Sheridan with an opportunity for indulging in his wit. It is related that he was dining with Lord Chancellor Thurlow on an occasion when some Constantia was produced which tickled the palate of the connoisseur so much that he set his wits to work to get more of it. The Chancellor, however, unlike Meredith's Sir Willoughby Patterne, was not easily induced to produce his rare vintage in such pro-

fusion, and Sheridan, realising that his endeavours were proving fruitless, turned to a gentleman next to him and said: "Pass up the decanter, for since we cannot double the Cape, I must return to Madeira."

Constantia is the prototype of all the Cape homesteads. In minor degrees its plan differs from all of the

THE MAIN GABLE, "GROOTE CONSTANTIA."

later houses in that the large hall is in this instance placed longitudinally instead of across the building in order to avoid the natural fall of the ground. Like all the other early homesteads, it is built of small bricks and plastered. The main roof is well but simply constructed of timber cut from the silver trees once so plentiful along the mountain side, and is thatched with reeds. A typical feature of the house is the provision against fire from the thatched roof. It consists of a layer of clay, which is placed above the beams of the ceiling, and is sometimes covered with brick. Locally this is known as "brand solder," or fire loft. The space thus formed in the roof was generally used as a storehouse for forage or for drying fruit and was reached by a flight of steps from outside. Light was procured from a window in the main gable. In this instance the gable is decorated with a plaster figure symbolising Constancy, attributed to the sculptor Anrijt, who is also supposed to have created the remarkably fine decorated pediment to the wine cellar representing a Bacchanalian scene. The house possesses all the essentials from which the style of the surrounding homesteads sprang. There is the decorated gable which varies considerably in form throughout the Peninsula, and is undoubtedly of a South Netherlands (Flemish) origin; the stately entrance door with its fanlight, which had not yet begun to be carved into those exquisite forms which are found in the later work; the well-proportioned sash windows set almost flush with the wall face, and framed in heavy teak, with solid teak shutters for protection to the lower half. The iron hinges and brass work, which in all the old homes were usually of excellent quality, are in this instance attributed to a locksmith who touched at the Cape on his way to Batavia, and was detained by Van der Stel, to the great indignation of the company's directors.

Whoever may be responsible for the metal and brass-work which adorns most of the old doorways must have been master craftsmen, for in almost every instance there is a finish, a knowledge of the limitations of the material, and a refinement of design such as is rarely surpassed in door furniture. There can be no doubt that a considerable amount of this decorative work and the ever-increasing tendency to elaborate the modelling of the gables and plasterwork generally owed its origin to the influence of the French Huguenots who fled to South Africa after the revocation of the Edict of Nantes. This idea is emphasised by the more pretentious forms of the gable found around French Hoek, which was their first settlement.

Town Houses.

The town houses, the more important of which were designed by a French architect named Tibbault, naturally differed from those in the country, the chief alteration being that they were frequently two-storeyed and

had flat roofs. The open stoep—always an important feature of the work—was usually very high and approached by many steps. At either end was built a seat where servants waited whilst their masters and mistresses paid their calls. The façades of all the two-storeyed homes are even simpler than the country houses. With the flat roofs the gable, of course, disappears, and in its stead there is a well-designed cornice running the entire length of the house. In a few instances the façade is relieved by Doric pilasters, now and again fluted. On the flat roofs of the town houses they built a small room or "observatory," from which the anxious inmates of the home eagerly scanned Table Bay in search of vessels, few and far between, bearing news and tidings of the homeland. The remaining features of the town house were again those found in the country homes—the carved fanlight, the stately entrance door, and the well-proportioned sash windows. The only other distinctive detail, also introduced into Ceylon by the Dutch, is the detached belfry found near most of the farm homesteads. This was used for rousing the farm hands, sending them to the plough at sunrise, and calling them from the fields at noon for the midday meal and to rest at sunset.

Dutch Furniture.

Dutch furniture possesses a fascination for the collector nowadays because of its splendid craftsmanship. The love of soft wavy lines has given to their huge wardrobes bedecked with silver-mounted handles and escutcheons a charm particularly their own. How far these were made locally it is impossible to say, although the use of South African woods, particularly stinkwood, is a considerable argument in favour of the theory; certain it is that much more is attributed to the colonists than actually was wrought by them. Furniture more or less of the Dutch pattern is found throughout the East, as is that of the Portuguese, for these two nations bartered their marqueterie, cabinets of ebony, and their porcelain with the Celestial, who not infrequently added to them his own lacquer. This probably explains much of the work and decoration of the tall clocks and cupboards occasionally inlaid with ivory which have found their way back from the East. The one outstanding feature of Colonial furniture is the seating to the chairs. For this thin leather thongs were used, well "breied" or tanned in the sun,

THE WINE FARM, "GROOTE CONSTANTIA."

AN OLD DUTCH DWELLING IN CAPE COLONY.

and then strapped across the chair each way about an inch apart. These are known locally as "reimpje" seats, and when well prepared endure years of hard wear.

Homer painted the whole picture of the sense of quiet dignity which is written over the doorway of these Cape homesteads in one beautiful line of the "Iliad":—

His home stood by the wayside, and every wayfarer was his welcome guest.

They tell of years of kindly hospitality and good will, not unnaturally the outcome of poor human souls who, after inheriting 200 years of unrest, of persecutions and intrigues, revolutions and wars, were able to find peace in the cool sequestered by-ways of the Cape. Wherever they settled they built their house, with its large hall, from which the bedrooms and the kitchen led directly off. They decorated it with quaint gables and a beautiful door, in two halves, in the country, so that when the upper half was left open the lower one might keep out the poultry, sheep, and calves of the farmyard. They planted orderly avenues of spreading oaks, and guarded the entrance by massive gate piers, and around this made their vineyards, which ran out as far as the eye could see, until they ended in the ever-changing hues of the veldt beyond. The streams which tumbled noisily over the river stones they led past their wine cellars and stoeps and enclosed them in canals, with quaint curves and piers; and often on the mountain-side near by is seen the small white-walled "Campo Santo," shaded by gnarled oaks, where sleep "the rude forefathers of the hamlet." These old homesteads ever hold for those who care to seek one great abiding charm in the quality of repose and the absence of pretension. At one time on their stoeps—the unfailing appendage of every Dutch house—stout burghers and their wives gathered to talk and laugh and make merry, and welcome the occasional guest from beyond the seas. They are relics of a bygone day and emblems of a storied past before wealth and struggle and strife brought the land into closer contact with civilisa-

tion. Each of these buildings is handed down as a national asset which can never be increased; each

solid frame is pledge of future glory,

And links our doings with our country's story.*

South Africans would do well to pause and consider whether sufficient attention is being paid to the preservation of these relics of bygone days. There must be many who regret the gradual disappearance or disfigurement of the beautiful old homesteads and the passing out of the country of many of the choicest pieces of furniture. The preservation of these noble relics of the past should be an act of pious duty. If this is neglected and injury to and destruction of these precious remains of the old Dutch colonists proceed unchecked, their entire disappearance is but a matter of a few years, and with it must go much pride of race and tradition of descent.

The intermediate period between the early settlers and those building to-day was productive of a great amount of spurious work done by irresponsible builders who, arriving at the time of the first discovery of the mineral wealth of the country, began to erect dwellings without any idea of considering the climatic conditions or pressing into their service any of the natural resources of the country. Homes were wanted rapidly by a fast-increasing population, and they were supplied in the easiest manner—by reproducing *in toto* the ordinary jerry-built villa which abounds in Northern Europe. Ill-educated individuals possessed only of the merest superficial knowledge of their work gave to the public, whose character was moulded into a craving for actuality, what they wanted. For many years the stock cornice, cast-iron column, and corrugated iron roof reigned supreme; and to those were added decorations of the most tawdry description, so that the architecture of this period is of little or no historical value except to prove the derogatory effect sudden wealth may have in the moulding of a nation's taste.

* "To the Old Drostdy Tulbagh," by F. C. Kolbé, D.D.

THE STREET NAME-PLATE PROBLEM.

BY RAE DOUGLAS.

I HAVE noticed that, for some years past, THE ARCHITECTS' AND BUILDERS' JOURNAL has seized every legitimate opportunity of advocating a more rational and more artistic method of labelling streets, and I cannot resist the conclusion that the persistency with which you have called attention to the need for reform must have had very considerable influence on the decision of the R.I.B.A. to call a conference on the subject.

Strolling round a few streets in and near London, with the express object of taking observation on this subject, I soon saw that such an investigation might be made to yield a good deal of interest and amusement. It would be easy, I should think, for any one who had the leisure, to make a collection of curiosities in street labelling. Of course, I do not mean that, after the manner of Tom and Jerry, who collected door-knockers by the brutal process of wrenching them off, the street name-plates should be taken away bodily. Those that seemed worth it, however, might be taken with a camera.

The few specimens of which I venture to send snap-shot photographs are neither curious nor amusing. They are, on the contrary, rather depressing, and all the more so because they are just average specimens of current practice. Their main service is, I think, in showing how the thing is commonly done, and, incidentally, how it ought not to be done.

The City of Westminster must be credited with having taken the matter in hand with considerably more thoroughness and energy than can be easily discovered elsewhere. Apparently every street corner is labelled; and there has been adopted a uniform pattern, of which the "Ashley Place" sign is an example; although a few earlier and unstandardised labels that have weathered well have been allowed to remain unspersed. The standard form, however, preponderates overwhelmingly, in more than one sense of the adverb. Where thoroughfares intersect, and four or more such conspicuous labels are within sight at once, the effect is more striking than elegant; and the fourfold reminder that one is in the City of Westminster grows somewhat tiresome by its congested iteration.

Nor is the standard Westminster label by any means a thing of beauty. The best that can be said for it is that it is certainly legible from the other side of the

essential parts. There is certainly no need to search for it. It shouts at you from afar, although, for the reason already stated, its message may not be quite clear until you get near enough to correct the halation. The Underground Railway labels its stations with white lettering on a dark blue ground, and as regards distinct visibility this combination is very effective; although I dare say there are many persons who would agree with me that a dark blue background is aesthetically abominable. This same combination of blue and white, if memory does not play me false, is used for the uniform labelling of the streets of Edinburgh, where the melancholy tint combines with the uncompromisingly inelegant and baldly utilitarian block-letters to produce a most depressing effect on the passer-by. If it be reprehensible "to paint the town red," it is no merit to paint it, *passim*, in the peculiar hue of melancholy mania; and the inelegance of the lettering is the more deplorable from its strong contrast with the beautiful eighteenth-century characters, effective but unobtrusive, and as a rule beautifully proportioned to the scale of the building, which smile serenely upon us from the fascias of the shops in Princes Street.

The Edinburgh labels, I believe, are destitute of framework. The woodwork surrounding the Westminster plates is rather too heavy, perhaps to give it the necessary strength for fixing. One's first impression of these plates—an impression that probably in many instances remains uncorrected—is that the labels are printed from type on paper, and framed and glazed. This idea, as I have shown, is quite erroneous; but it ought not to arise, because it not only suggests the cheapest and most unenduring (and unendurable) form of street label, but one that, for these and for other reasons, would be indefensible. On the whole, I do not think that the Westminster plate is a good model for imitation; nor do I think that it is possible to devise a plate that shall be uniformly appropriate to all styles of building and all situations on or about a building.

Generally, the Westminster plates are fixed on the corner house, at a little below the level of the first-floor window; but occasionally, as in the case of the Ashley Place label here shown, it is fixed on area or forecourt railings. The latter position seems to be in high favour in the suburbs, and is no doubt advantageous where forecourts are extensive, and where consequently a plate attached to the house would be too remote from the road, or might from other causes be rendered wholly or partly invisible. For example, the only label I could discover designat-

ing the High Road, Lee, was on the last house where one would have expected to find it—that is to say, at a point about a quarter of the length of the road, instead of where the road begins (or ends)—and since it is most effectually masked by a number of beautiful flowering trees, it was only by chance that I happened to discover it. In another case in the same district, at a street corner, the ampelopsis from the front garden has crept round the side of the house, and clearly a ladder must be brought into use at frequent intervals to keep the creeper off the plate.

Some further examples from the same district are doubtless typical of the practice in other suburbs. Formerly it was the custom to paint a white background on the wall of the house, and thereon to paint in black letters the name of the street. This absurdly primitive and expensive process is now being superseded by the adoption of cast-iron plates showing the name of the street in raised letters—dark, on a light ground. Where, as in the case of the Murillo Road example, these plates are within easy reach of the smallest child, the raised letters offer an irresistible appeal to intuitive artistry, which is expressed more or less broadly in white chalk. Similarly, a low-fixed white board, like that from Baring Road, is fortunate if it escapes the delicate attentions of the errand boy. Certainly the labels should not be within his reach.

Street-corner boards indicating churches, etc., illustrate a pious custom that, while doubtless admirable in intention is apt to be rather unedifying in aesthetic result, and were perhaps more honoured in the breach.

As to the matter of direction labels, I notice that some small attempt of the kind is occasionally made. You will sometimes find a plate inscribed, "So-and-so Street, leading to such-and-such Square," and so on. This is doubtless very useful—by daylight; but I have an idea that a specially designed lamp standard, not necessarily inartistic, should show, by night as well as by day, a complete list of the subsidiary turnings in a main street, so that the wayfarer might know at a glance which main street to strike in order to come upon the side street of which he was in search. Church, post-office, fire station, or other public-utility building, should find a place in the list.

I had hoped to find in the City of London some exemplary street name-plates, but my search was disappointing. The names of streets, courts, and alleys seem to be indicated in every conceivable variety of bad taste. The most prevalent, and, on the whole, the most efficient, label seems to consist of separate letters of enamelled iron—white letters on dark-blue ground—gathered together in a grooved frame (or, where the name is a long one, in two or three grooved frames), in the manner in which infants are taught word-building. The resultant appearance is exigent and patchy; and in several instances in which three frames have been found necessary, the relationship to each other in which they have been placed seems to have been determined by the momentary whim or mood of the fixers. Given three frames, their possible relative positions are fairly numerous; and in the City most of the legitimate possibilities seem to have been realised. The various ways in which those combinations are grouped and spaced shows an

road, and that the lettering is inoffensive as to style. The label appears to be made of some vitreous material, and the lettering is black, except "S.W.," which is sometimes of a paler colour, on a white ground. I do not think that a white ground tends to legibility at a distance. It sends out a sort of halation, which rather swamps the lettering, or at least to blur its edges and render its outlines hazy and indefinite. A reversal of the colours would give greater sharpness to the lettering—that is to say, light lettering on a dark ground would stand out more distinctly than dark lettering on a light ground. The Westminster label as a whole is more conspicuous than its

For the Johannesburg Art Gallery Mr. Havard Thomas has been commissioned to execute in bronze his statue of "Thyrsis," the wax model of which is at present exhibited in the Royal Academy. This has been brought about through the generosity of Mr. Max Michaelis.

The method of setting up perspective here described has several marked advantages over the ordinary more cumbersome systems. It is based upon the elementary method of setting up an auxiliary elevation of the object and a section of the picture plane and drawing side elevations

We fear there is not very much to be said for the present exhibition of the New English Art Club. Fine effects of lighting there are in such open-air pictures as Mr. Von Glehn's "New England" and "The Picnic"—the latter a large painting of a group of people under trees, through which come dashes of sunlight, while a girl who has been bathing pushes her way back through the bushes in her swimming garment; altogether a very joyous kind of picture. Mr. W. Rothenstein's "The Princess Badroulbador," three children in Orient-

tal costume, is a fine piece of colour, but the heads are the least satisfactory part of the picture. They are not, however, studiously ugly, as we find so often to be the case in these exhibitions. Mr. Orpen paints a three-quarter length under the title, "The Chinese Shawl," very clever and effective in the draperies, but with a face of the most unattractive character; and, again, in his almost grotesque picture, "The Café Royal," we find a composition of gilded ornament and personages of the lowest type; and Mr. Orpen can paint so beautifully if he chooses! Miss Alice Farmer's seascapes are, as usual, full of air and brightness. Among other things that come as moments of refreshment to the eye amid so much that is eccentric and ugly are Mr. Mark Fisher's "Spring"; Mr. Sargent's brilliant sketch called "Fabalas"; Mr. Von Glehn's "The Green Hat," a portrait in which for once we are allowed to see a pretty face; Mr. Somerville's still life painting, "Honesty and Other Things"; and Mr. Shepherd's really pleasing and interesting interior with figures, entitled "A Music Party," which seems quite out of place among its surroundings. Mr. Sydney Lee would be wiser to keep to the architectural subjects which he paints so well; his figure picture of "The Gendarme and the Peasants" is not a success.

Plaster Reproductions of Sculpture.

At the Gallery of the Medici Society in Grafton Street is a collection of "plaster reproductions of antique, Renaissance, and modern sculptured masterpieces," by Miss Nelia Casella. Miss Casella's coloured gesso bas-reliefs have for years been familiar to frequenters of the Royal Academy sculpture room. What she has done in the works exhibited at the Medici Gallery has been, apparently, to take casts from sculpture and work them up into an exact resemblance to the original material. One of the best of these appears to have been oddly misnamed in the catalogue; this is a bust by Mino da Fiesole, worked up in the plaster by markings and colour to a perfectly realistic representation of a head carved in wood, yet it is marked in the catalogue as from a marble original. This must be a mistake! There are reproductions of works by Pollainolo, della Robbia, Donatello, Desiderio di Settignano, and other Renaissance artists, all exceedingly well done. We take it that No. 11, entitled "Minerva (imitation of the Renaissance style)," a splendid profile in bas-relief, is the design of Miss Casella herself. It is one of the best things in the collection, and is in the very spirit of Renaissance art. The collection is on view till June 22nd.

ARCHITECTS' FEES.

By consent, judgment has been entered for the plaintiff for 25 guineas and an agreement that the defendant shall return all drawings in the action raised by Mr. William Davidson, architect, of Edinburgh, against the Rev. Charles Wilton Prangle, Bexwell Rectory, Downham Market, Norfolk, which had been set down for trial on May 30th. The claim was one for 50 guineas for services rendered by the plaintiff in preparing designs for a proposed restoration of Potter Heigham Church, Norfolk, and the defence was that any work which the plaintiff had executed was of the nature of an expectation that he was to be the architect in the event of the restoration being proceeded with. The defendant had accordingly denied employment.

LONDON BUILDING TRADES AND THE TRANSPORT STRIKE.

Builders, in common with others who are more or less dependent on the water-borne transit of goods, had just begun to congratulate themselves on the impending termination of the transport workers' strike when it suddenly entered upon a disconcerting new phase.

At a conference of the societies affiliated to the London Building Industries' Federation, held on Saturday last, the following resolutions were unanimously carried:

1. That this Conference, representing the whole of the building trade, withdraw all their members now employed by the Port of London Authority forthwith.

2. That societies affiliated to this Federation instruct all their members to cease work at once in shops or on ships on the River Thames if non-union labour is brought in to do the work of the members of the Transport Workers' Federation.

The immediate effect of this was that several thousands of men were expected to "down tools" on Monday, and that where they are requested to work on the Thames generally with non-union men, others would also cease work.

Saturday's conference was attended by nearly eighty delegates, and an idea of the trades represented, and consequently concerned in Saturday's strike, may be gathered from the following list of the industries represented: Amalgamated Society of Carpenters and Joiners; General Union of Carpenters and Joiners; National Association of Operative Plasterers; United Operative Plumbers; National Amalgamated House and Ship Painters and Decorators; Engine and Crane Drivers; London United French Polishers; Electrical Trades Union; General Smiths, Fitters, and Hot Water Engineers; National Society of Smiths and Hammermen; Operative Stone Masons' Society; Amalgamated Society of Woodcutting Machinists; United Builders' Labourers' Union; Gasworkers' and General Labourers' Union; Navvies and General Labourers' Union; United Order of General Labourers' Union; Operative Bricklayers' Society.

The Conference lasted over three hours, and during the sitting a deputation from the Transport Workers' Disputes Committee, consisting of Mr. Ben Tillett, Mr. J. Jones (secretary), and Mr. Cone (chairman of the London district), attended and reported on the present condition of affairs so far as the London dispute was concerned. The resolutions were referred to the Executive Committee of the London Building Industries Federation to carry into effect, and the men received their orders by first post on Monday morning.

As the whole of the maintenance staff of the Port of London Authority is affected, the matter assumes considerable importance, and serious added difficulties will be thrown in the way of those responsible for the management of the huge docks under the Authority's control.

It was stated that the calling out of representatives of the building and affiliated trades in the Port of London was not only done on sympathetic grounds, but because the members of the federation had themselves serious matters of dispute with the Port of London Authority.

In order to obtain authoritative information upon so important a crisis, a representative of this journal called on Mr. Thomas Costigan, the secretary of the London Master Builders' Association, who, on Monday, stated that in his opinion this new phase of the strike of transport

workers had no immediate bearing on the threatened general strike in the building trades. These two movements, said Mr. Costigan, are quite separate and independent. Although certain men connected with the building industry—such as ships' carpenters and painters—are concerned in the present strike at the dockyards, the trouble, as Mr. Costigan pointed out, is primarily due to the employment of non-unionists. Moreover, Mr. Costigan is very hopeful that there will be no strike in the building trades during the present year. The negotiations between the L.M.B.A. and the representatives of the men have been conducted with the utmost fairness on both sides, and there is every prospect of an amicable settlement at an early date. This is indeed welcome news in a moment of anxiety and depression, and we are glad to be able to announce it.

ART AND ADVERTISEMENT.

"Every Form of Art is Advertisement" was the subject debated at a dinner held on Saturday evening at the Belgrave Club, London, W. Mr. John Hassall, in opening the debate, said that in the earliest days the drawings done by prehistoric man in the cave dwellings were not "Art for Art's sake." They were advertisements or tokens used by the tribes, and were still with them at the present time. These drawings nearly always represented animals, and among the living artists who still scratched, and whose names recalled the old tokens, many of them were direct descendants from the old cave men, only they did not know it. The Sphinx was only an advertisement for the adjoining temple, and it was not with any idea of keeping the thing quiet that they made it with such a huge head, for if the rock had been larger the Sphinx would have been bigger. The hieroglyphics on the mummy cases, and even on the Pyramids, were intentional advertisements of the departed. The Greek art was such an advertisement for themselves that when Rome took the top place among the nations she imported all the finest Greek artists available to decorate Rome and in order to learn from them. The Italian Renaissance was also purely advertisement. They wanted to get the people into the churches, and they painted religious pictures inside, so that the pictures could not be seen without entering the church. Stained-glass windows were for the same idea; people had to go inside the church to see them.

The beautiful recumbent stone effigies of crusaders and bishops and others were only made to advertise the families of the deceased. At the present time he was given to understand that every artist in an exhibition hoped that his picture would attract more attention than the other contributions, either on account of the idea, the technique, or the frame. If it was "Art for Art's sake," they would be just as pleased to see their picture standing in the passage. Every portrait painted was obviously a personal advertisement, for no one ever heard of the portrait of a mayor being painted without his chain of office, or an officer without his medals. And the people who got free advertisement, like Guy Fawkes or Bernard Shaw, really did not require it.

Mr. Walter Crane said that a remarkable light had been thrown on the early tribal habits of man. He had often been struck with the magnificent possibilities of the modern poster, but he always felt that from the sublime to the ridiculous was but a step, and it was a step that was frequently made.

OUR PLATE.

The New Pavilion at Margate.

The site for the new pavilion and concert-hall at Margate was formed by removing the cliff at the old Fort Green, and the building was erected in the opening thus made. This was rendered necessary by the fact that certain houses facing the sea possessed rights of uninterrupted views, which made it impossible to put any building above the promenade.

The concert-hall was sunk so that the floor is about 8 or 10 ft. above the level of the sands and about 35 ft. below the top of the cliffs; the building is protected from the sea by a strong retaining wall. The roof of the pavilion is level with the cliff promenade, which it links up, forming a continuous walk over the building.

The principal elevations are towards the land and the sea and the concert-hall proper, which occupies the greater part of the site, is screened on these sides with glass fronts, affording the spectators an uninterrupted view over the sea, and directly connecting the hall with the open-air theatre on the land side. The stage is placed in the centre of this side, and is available for performances both from the arena, which is designed somewhat on the lines of a Greek theatre, and from the concert-hall. In wet or cold weather the south part of the stage can be shut in by means of folding shutters and the audience will then be in an enclosed hall.

The concert-room is 140 ft. long and 95 ft. wide, the central portion of which is 55 ft. in width, and the roof over forms the promenade already referred to; this is supported by curtain walls with windows at regular intervals, carried by sixteen Corinthian columns.

There are two galleries for spectators, so arranged that they can be used for orchestral and choral performances. They are approached from the hall by four wide

stone staircases. At either side of this central space are side wings 20 ft. in width and about 18 ft. high from the floor to ceiling, with four entrance halls, one at each end of these wings.

Provision has been made for large reading and refreshment rooms, with lavatory accommodation for both sexes on the ground floor, and rooms for the staff and management over.

The rooms for the performers and bandmen are placed beneath the stage.

The excavated portion of the ground on the land side of the pavilion is laid out as a winter garden, with terraces and winding paths protected from the north and east winds; these paths give access to the concert-hall at the ground-floor level, while additional entrances are provided over the roof of the colonnade at the back of the open-air theatre.

Altogether accommodation has been provided for about 5,000 persons—2,500 inside the building, 2,000 in the arena and on the upper part of the colonnade, and 500 on the balcony and promenade facing the sea. Externally the building is finished with Portland cement stucco coloured to a creamy white, and the interior of the concert-hall is carried out in plain white plaster with fibrous enrichments. The architectural treatment is very Greek in feeling, and there is a faint suspicion of French influence. The general design of the concert-hall is suggestive of the work of the French *néo-Grec* School, and this is particularly evident in the character of the details.

The contractors were Messrs. T. T. Denne, of Walmer; the steelwork was carried out by Messrs. Goddard, Massey, and Warner, Nottingham; the internal decorative plaster work by Mr. Gilbert Seale, London; the external plaster work by Messrs. Nicholls, of Coventry.

The building is the joint work of Mr. Ernest A. Borg, C.E., the Borough Engineer, and Mr. Stanley C. Ramsey, A.R.I.B.A., architect.

FIRE PREVENTION NOTES.

A Prolific Cause of Fires.

A contemporary is much struck with "the great extent to which fires in this country owe their origin to carelessness." Yet one would have thought that the most obvious thing about fires was that carelessness of one form or another was at the bottom of almost every outbreak. The specific kind of carelessness to which our contemporary refers—that of throwing down lights—is only one among many, but it is the one that receives most attention simply because it is the one that is most common and obvious. But is not this gross carelessness symptomatic of the general public apathy with respect to fire? An un-instructed public could not be expected to restrain the natural impulse to fling down a smouldering match or the end of a cigar or cigarette without a thought as to the possible consequences. The sense of moral responsibility in such matters is not, as it should be, persistently and patiently developed in the home and in the school; and it is because of the prevalence of this crude ignorance in purely elementary matters that so little progress is made with those that are more advanced. The public conscience with respect to fire prevention has not been awakened. In the United States an effort is being made to arouse it by making penal the throwing down of lights, and a similar proposal for our own country should not lack supporters, considering that, of the fires that occurred in London alone during 1911, no fewer than 1,308 cases are attributed to the careless throwing down of lights.

Ignorant Carelessness and the Remedy.

A few prosecutions of those guilty of the criminal folly of throwing lights about would do more than discourage this insane practice. It would go some way towards establishing a better all-round appreciation of the importance of fire-prevention. If the subject received due attention in our elementary schools, another very prolific cause of fires would be minimised. The servant-maid would at least know better—even if she did not invariably apply the knowledge—than so to dispose of smouldering ashes as to increase very largely the number of outbreaks of fire. Then, with the removal of elementary ignorance, and its concomitant crude carelessness, would come the realisation that fire-prevention precautions would be better worth while. Of course, theoretically, the greater the prevalence of danger from common carelessness, the greater the need for fire-prevention precautions, and this theory certainly operates to a certain extent. But, on the other hand, the advocate of fire-prevention construction is commonly met with the objection, "What is the use of my taking all these elaborate precautions when they may all be instantly nullified by some reckless fool flinging a lighted match or cigarette-end among the inflammable goods?" This is at all events a very effective excuse, although it will not bear a strict examination as to essential soundness, but most of its force would be lost if culpable carelessness became punishable by law. Already the smoker has been taught that he may not foul the floor; it would therefore be the easier to teach him, on similar terms, that he may not with impunity fling fire about. Then probably the constitutionally conservative (not to say parsimonious) building client would shift his ground, seizing

on the excuse of people having become so careful as to render elaborate fire-prevention precautions unnecessary! The normal man, however, always feels that a movement seen to be good ought to be appropriately supported. Surely, if somewhat slowly, the cult of fireproof prevention is growing, and the proposed American enactment with regard to light-throwing is symptomatic of the fact.

The of the destruction by fire
Archæologist's (last month) of what is
Arch-Enemy. described as "a thirteenth-century house," even though one does not overlook the possibility that the earliness of the date may have been exaggerated by a century or so. Whether or not Hardham Priory, near Pulborough, in Sussex, was correctly described as a thirteenth-century building is now, alas, of considerably less interest than it was before the fire, which has left only the bare walls standing—whether or not in a condition to admit of preservation is not recorded, but one hopes for the best, since houses of anything approximating to the date indicated are becoming very scarce. The fact that fire is the archæologist's arch-enemy, destroying sooner or later all that he holds precious, should move him to take action with the object of preventing its ravages.

Has it occurred to the
Ancient Society for the Preserva-
Monuments. tion of Ancient Monu-
ments to take any steps
to preserve such monuments from the most prolific cause of destruction? If not, they might render excellent service by specially addressing themselves to this point. A White Paper that has just been presented to the House of Commons contains "Reports from His Majesty's Representatives

Abroad Showing the Systems Adopted in Certain Foreign Countries for the Preservation of Ancient Monuments." Fifteen countries are included in the inquiry, but in no single instance is it made clear that fire, the most destructive agency of all, is specifically taken into account. Indeed, so far as a rapid glance serves to determine the point, it does not appear that, in all the twenty-eight pages of which the White Paper consists, the word "fire" is once mentioned, although it may reasonably be presumed that such a contingency cannot have been overlooked, but is probably implied in such provisions as that of the Church Inspection Law of Denmark, which enacts that cathedrals and other important churches are to be placed under the supervision of a special council consisting of "two architects and an archæo-

logist"—an admirably balanced proportion from the architectural point of view!

"Monuments" that are worth preserving are, in spite of the popular misconception of the word as referring to something solidly stony, mostly things that will burn; and to this effect the archæological societies should take to heart the derivation of the word—from *moneo*, "I warn." The Commission on Ancient Monuments has provoked a crop of Parliamentary Bills and White Papers: is it not time that we had a Commission on Fire Prevention? Its conclusions should be of the utmost practical value for the preservation of what is standing as well as for guidance as to future construction.

INTERIOR OF CONCERT HALL, MARGATE.

BUILDERS AND THE INSURANCE ACT.

With regard to the effect of the Insurance Act on the building industries, among the many difficulties that are likely to arise, not the least is that of deciding exactly what workers are included under or are excluded from the operations of the Act. An Umpire has been appointed to consider and decide upon such points, and, pending the publication of his decisions, the following views of a well-qualified expert will be found interesting. They are of course unofficial.

THE approach of July, in which month the Unemployment Sections of the Insurance Act will come into force, will naturally cause those engaged in any of the insured trades, either as employers or workmen, to become keenly interested in their standing in relation thereto. Amongst these are the men engaged in the building trade and allied vocations, such as constructional work in docks, railroads, bridges, etc. The part of the schedule of the Act which mentions these vocations is perhaps worth quoting in full so far as it affects readers of this journal. It is as follows:

"(1) Building; that is to say, the construction, alteration, repair, decoration, or demolition of buildings, including the manufacture of any fittings of wood of a kind commonly made in builders' workshops, or yards.

"(2) Construction of works; that is to say, the construction, reconstruction, or alteration of railroads, docks, harbours, canals, embankments, bridges, piers, or other works of construction.

"(7) Sawmilling, including machine woodwork carried on in connection with any other insured trade, or of a kind commonly so carried on."

Wide as this schedule is, any practical builder will see at once that there are many employers and men engaged in work which is on the borderline of the Act, and many applications have been made to the Umpire appointed under this part of the Act for his decision on crucial points. The following is a list of the vocations which have been under consideration with regard to their position under the Act. The footnote in each case is the present writer's opinion as to what the decision should be:

Masons.—Banker hands, described as working stone with chisel and mallet to finished dimensions in quarrying districts and generally in connection with building operations.

NOTE.—These workmen are preparing work to be afterwards used in a building. They are not necessarily stone fixers, although possibly capable of doing the work. They occupy a relatively similar position to joiners in a shop who are included under part 7. It would therefore appear to be logical that they be included.

Fitters, joiners, smiths, bricklayers, and their labourers, employed solely in the work necessary to the erecting, driving, and upkeep of plant and machinery used in the mills and in the upkeep of the premises of a firm whose business is that of seed crushers, oil cake manufacturers and oil refiners.

NOTE.—The business of the firm is immaterial. The men are engaged in building repairs and machinery repairs principally, with such new work as may be necessary. As the work of construction, alteration, and repair of buildings and every branch of engineering, are included, these men should come within the Act.

Brickworks.—Persons engaged in (a) making stock bricks by machinery; (b)

the burning of bricks by open clamp fires.

NOTE.—Brickmaking is in effect the creation of raw material for builders. It occupies practically the same position as making cement or plaster. It is true they are made to finished dimensions but this is simply a trade requirement and not to order. A brickmaker is not a builder's mechanic by trade custom, and therefore should not be included.

Men engaged in road making, road maintenance, sewer laying, sewer repairs, street cleaning, water inspectors for town supply.

NOTE.—The first four of these are undoubtedly within "construction of works," and should be included. Street cleaning is primarily a sanitary requirement, and should therefore not be included. Water inspectors are appointed to detect faults which cause financial loss to the town. They are not, when so engaged, mechanics, although, as with sanitary inspectors, a due performance of their duties may cause certain works to be put in hand. They should not be included.

Paviors, Platelayers, Labourers, Carters employed in repairing and maintaining tramway tracks and at times renewing same.

NOTE.—Clearly all are working within the term "construction of works," although "tramways" are not specially mentioned in the 6th schedule of the Act. A carter is as particularly necessary to the works as a hod carrier or any other man engaged in carrying.

Bricklayers, Slaters, Labourers, and Carters engaged at times in the maintenance and repair of tramway depôts and other buildings the property of the company.

NOTE.—Should be included when so engaged, as these are distinctly building operations.

Men employed (a) in saw mills entirely in making packing cases.

NOTE.—This is not machine woodwork carried on in connection with any other insured trade, and should therefore not be included.

(b) Joiners, carpenters, and mechanics in engineers' department of soap works.

NOTE.—It is distinctly stated in the Act that it is work done, and not the employers' business, that has to be considered. Therefore these men should be included.

Men engaged in Dye Works as painters.

NOTE.—If on building repairs are certainly included. As before stated, the business of the firm is immaterial.

*Masons** engaged partly on monumental memorials and partly on building fronts.

*Masons** engaged in monumental work with mallet and hammer and chisel, preparing monuments and erecting same in cemeteries or public places.

*NOTE.—To take these together, a monumental memorial of the nature of the Prince Albert Memorial in Hyde Park is undoubtedly a work of construction. An ordinary tombstone in a cemetery hardly falls within this description. Between the two there is a wide range. Statuary, drinking fountains, chapels, may all be

memorials. If reference be made to the business of the employer, nothing definite is gained, because small builders often erect tombstones. As the work is that of dressing stone, and this is principally a building operation, the men should be included.

Masons engaged with hammer and chisel in preparing paving stones for foot-paths and setts for carriage ways.

NOTE.—This is an integral part of a work of construction and the men should be included.

Men engaged in Polishing Granite and Marble for use in connection with buildings.

NOTE.—See previous note.

Stone Sawyers (machine) and other machinists employed in dressing stone.

NOTE.—If sawing stone for market these men should not be included; but to given dimensions, and if for the direct purpose of building or use in works of construction, yes.

Cutting Stone with Hand Saws for use in connection with buildings or works of construction (a) in quarries, (b) in stone-dressing yards attached to quarries, (c) in stone-dressing yards carried on as separate businesses or in connection with the business of a builder, (d) on building jobs.

NOTE.—The men should be included in each instance if the work when finished is for direct use in a building or work of construction. If only a preparation of raw material, then no.

Men engaged in Quarrying Stone, including the process of scabbling or other rough dressing.

NOTE.—If the work is to be used as it leaves the quarry, yes; otherwise, no. There must be a distinction between ordinary quarry work and building work. Quarries are not included in this part of the Act.

Cabinet Making.—Men employed in making staircases, wall and ceiling paneling and general house fittings in hard wood made in shops by those who may or may not be employed to fix the same in the house.

NOTE.—As men engaged in the manufacture of any fittings of wood of a kind commonly made in builders' workshops or yards are included, it appears probable that these men mentioned above would also be included.

Cabinet Makers and Fitters engaged in machining and putting together school furniture of a movable description and not usually made in a joiners' shop, also church furniture of the same description that does not form part and parcel of the building fabric.

NOTE.—This work is not within the scope of the building trade, and therefore should not be included.

Bridge Carpenters.—Maintaining all timber work in the various bridges on a company's railway, including the inspection and replacing of defective material.

NOTE.—This is undoubtedly work of repair. It is not specifically mentioned in the schedule, but may be easily termed reconstruction, although only on a small scale, and therefore appears to be included.

In considering these points it should be remembered that the Board of Trade can rule out any description of labour, even after the Umpire has decided it may be within the Act. For instance, carmen when employed in the building trade may be excluded, because their work is only incidental to the trade of the employer, and they are not builders' workmen in the correct sense.

COMPETITIONS.

The Australian Federal Capital.

The assessors in this competition, with the conditions of which, it will be remembered, the various organisations of architects were in disagreement, advising their members not to compete, have made the following awards: 1 (£1,750), Walter Burley Griffin, Chicago; 2 (£750), Eliel Saarinen, Helsingfors, Finland; 3 (£500), Alfred Agache, Paris. The assessors were Mr. J. H. Smith, Mr. John Kirkpatrick, and Mr. J. M. Coane.

The judges of the architects' designs for the Australian Federal capital city at Canberra had finally reduced the number of plans under consideration to six. These designs, the "Westminster Gazette" states, were all for a radial system of construction, and the architects who submitted them are, it is understood, none of them British. It has been suggested that two prizes may go to Germany and the other to the United States. The plans, generally, take a wide range. There are castles and towers and minarets and lakes and rolling streams, and provision for Parliament buildings which must outpace the dream of the most reckless Finance Minister. There is a gorgeous residence for the Governor-General in some; a luxurious palace for the Prime Minister in others. It is estimated that ten years will elapse before Canberra City will be sufficiently far advanced in being to house the Federal Parliament.

Whiteley Park Homes.

In the limited competition for laying out the site for the Whiteley Homes, which is to be known as Whiteley Park, the scheme submitted by Mr. R. Frank Atkinson was selected. Mr. Walter Cave, F.R.I.B.A., was the assessor.

Society of Architects' Travelling Studentship.

The travelling studentship (£25 and silver medal) for designs for a town hall to cost not more than £30,000 has been awarded to Mr. F. Morrell-Maddox, Burton-on-Trent.

Council School, Port Sunlight.

Messrs. George Bradbury and Sons, of Liverpool, have been appointed the architects to carry out this work.

LIST OF COMPETITIONS OPEN.

JUNE 14. ADDITIONS TO HOSPITAL, CONISBROUGH. — Doncaster and Mexborough Joint Hospital Board invite competitive designs (in sepia or Indian ink) for additions to their isolation hospital. Apply, H. M. Marshall, Clerk to the Board, Union Offices, High Street, Doncaster.

JUNE 24. KING EDWARD WELSH NATIONAL MEMORIAL. — Sketches for two sanatoria, one in North Wales, 150 beds, the other in South Wales, 250 beds. On preliminary sketches, not more than six architects will be selected to send full plans and details. Particulars from Secretary, Welsh National Memorial Offices, Newtown, Montgomeryshire.

JUNE 26. BATHS, BIRMINGHAM. — Twenty guineas for second, ten guineas for third design. Apply, Superintendent Engineer, Kent Street, Birmingham.

JUNE 28. TOWN PLANNING, HALE. — Premiums of £50 and £25 are offered for a town-planning scheme. Address, Council Offices, Hale, Cheshire.

JUNE 30. TOWN HALL, ETC., PADIHAM. — Premiums of £40 and £20 are offered

for designs for town hall, baths, etc. Particulars, Mr. J. Gregson, A.M.Inst.C.E., Surveyor's Office, Padiham. [Note.—R.I.B.A. have objected to the conditions.]

JULY 1. NEW OFFICES FOR THE PORT OF LONDON. — Limited to the six architects selected in the preliminary competition. [See our issue of April 10, p. 370.]

AUGUST 6. FIRE BRIGADE STATION, CARDIFF. — Cardiff Corporation invite architects to submit designs and estimates in competition for a fire brigade station proposed to be erected in Westgate Street, Cardiff. The Corporation have appointed Mr. A. Marshall MacKenzie, A.R.S.A., F.R.I.B.A., to act as assessor. Particulars on deposit of two guineas (returnable) from J. L. Wheatley, Town Clerk, City Hall, Cardiff.

AUGUST 30. SAXON SNELL PRIZE. — Fifty guineas, with medal, for essay on hospital construction. Apply, Sanitary Institute, 90, Buckingham Palace Road, S.W.

SEPTEMBER 30. NEW BUILDINGS, UNIVERSITY COLLEGE, DUBLIN. — The Governing Body of the University College, Dublin, invite architects to submit designs for new college buildings. Competition is limited to architects living and practising in Ireland. Applications, accompanied by cheque for two guineas (returnable) to J. W. Bacon, M.A., Secretary and Bursar, 86, St. Stephen's Green, Dublin.

OCTOBER 1. KING EDWARD MONUMENT, OTTAWA. — Sketch models, in plaster. Particulars, Secretary, Public Works Department, Ottawa.

NEWS ITEMS.

London University Site.

The Senate of the University of London has appointed a committee to consider and report on the question of an adequate site for the new headquarters of the University.

Change of Address.

Mr. James B. Dunn, F.R.I.B.A., architect, announces that, owing to the acquisition of his present chambers at No. 45, Hanover-street, by the Government, he has removed his office to No. 14, Frederick Street, Edinburgh.

A Reinforced Concrete Pavement.

A reinforced concrete pavement laid in Plymouth, Wisconsin, U.S.A., eighteen months ago has passed through two winters without showing any cracks or flaws, even along the street car tracks. Cypress wood is used for expansion joints, and a new form of rough surface has been adopted. The reinforcement consists of woven wire mesh. The surface finish coat was composed of crushed granite chips ranging from $\frac{1}{4}$ in. to $\frac{3}{4}$ in. in diameter, screenings of the same material from fine

dust to $\frac{1}{4}$ in., and Portland cement mixed in the proper proportions to give a very dense mixture. The reinforcement was placed directly on the concrete base immediately below the surfacing composition.

L.C.C. Fire Hydrants.

The London County Council have accepted the tender of Messrs. Ham, Baker, and Co., of Langley Green, for the supply of all the fire hydrants required for their area during the next three years. Several thousands of these hydrants are used.

Sewer Ventilation.

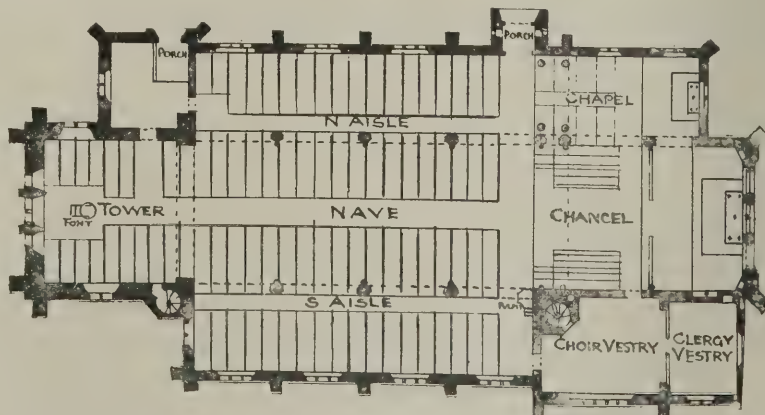

Three tests carried out recently with the patent sewer ventilators manufactured by Mr. R. H. Reeves, at Walton-on-the-Naze, by which cooled and chemically treated air is sent into selected manholes, showed reductions in temperature of 17 deg., 22 deg., and 13 deg. F. respectively 6 ft. below the apparatus, with the injection of 63 cubic feet a minute. The result was an absence of foul air in the sewers, with no possibility of noxious vapour escaping from manholes or being forced through traps by the sudden influx of storm water.

Bristol Society of Architects.

The Bristol Society of Architects have instituted a series of Saturday afternoon sketching expeditions during the summer months. The first of these took place on May 25th, the venue being Chelvey and Nailsea Court. At Chelvey the church and the manor house were visited, after which the party proceeded to Nailsea Court, the residence of Mr. Charles E. Evans. This delightful old house, with its recent additions and wealth of antiques, was studied with great interest. Apart from preserving the original building, Mr. Evans has collected and saved from destruction many valuable architectural features, some of which have been incorporated in the new additions, carried out under the supervision of Mr. Arthur Stratton, A.R.I.B.A.

CHURCH OF ST. BONIFACE,
ST. BUDEAUX.

St. Budeaux is an outlying district of Devonport, lying to the west of the town, and consisting almost entirely of a working-class population. The church is one of those being erected under the Bishop's Three Towns Scheme. The desire for a tower suggested the planning adopted whereby the tower is made an integral portion of the nave, so far as seating is concerned, the bells being rung from a gallery beneath the west window. The church is now in course of erection, Mr. G. B. Turpin, of Plymouth, being the contractor. Local limestone with stone dressings are the materials used. The architect is Mr. W. D. Caröe, F.R.I.B.A., F.S.A., of Westminster.

CHURCH OF ST. BONIFACE, ST. BUDEAUX, DEVONPORT.
W. D. CARÖE, F.R.I.B.A., F.S.A., ARCHITECT.

S. BONIFACE, BUDEAUX, DEVON.

W. D. CARÖE, F.R.I.B.A., F.S.A., ARCHITECT.
(Royal Academy Exhibition, 1912.)

PRACTICAL POINTS IN TOWN PLANNING.

THE proceedings of the National Advisory Town Planning Committee recently printed include four reports that have been respectively communicated by Dr. J. Robertson, medical officer of health to Birmingham City Council; Mr. Henry R. Aldridge, secretary to the Council; Councillor Harold Shawcross, J.P. (with diagrams by Mr. Raymond Unwin); and Mr. H. Lloyd Parry, Town Clerk of Exeter. Below are some practical points extracted from each of the reports.

Number of Houses to the Acre.

Dr. J. Robertson, M.D., B.Sc., reports on "Standards of Limitation of the Number of Houses per Acre, with especial reference to Public Health Considerations."

Those of us (Dr. Robertson writes) who did most to bring about Town Planning as we now know it will recognise that by far the most important object in view was the limiting of the density of the population in our towns, and particularly those towns in which the area covered is so great that the people living at the periphery lock in others residing in the centre and make it impossible for these dwellers to have clean air, or sufficient exercise ground, or sufficient privacy, or sufficient quiet, or freedom from dust. Naturally, Dr. Robertson thinks that the Public Health aspect of the problem is by far the most important one. Next in importance he would place the commercial aspect of it, and then what has been called the general convenience and artistic aspects.

It is somewhat difficult, he says, to demonstrate that density by itself is prejudicial to health. On the one hand we have examples of extraordinary crowding on space without producing what appears to the layman any specially bad results. For instance, we have in the Peabody Buildings a population of 21,000, with a death-rate of 12 per 1,000, and an infant mortality rate of 76 per 1,000 births. On the other hand, we have in one of the central areas of Birmingham a district containing a population of 14,000 persons with a density of one-sixth of that in the Peabody Buildings, but with a mean mortality rate of 23 per 1,000 and an infant mortality rate of over 200. Similar figures could be obtained for every large town in Great Britain. In the poor-class area of Birmingham, however, the houses are surrounded by brass-casting shops and by works of all kinds which produce smoke and noise. There is practically no green space in or near it, everything is dull, gloomy, and soot-begrimed, so that the relatively good density figure does not avail to make people healthy. In the flatted towns of America and of Germany we see clean people living what to outward appearance seem to be relatively healthy lives. In many of these block buildings the density runs up to over 300 persons per acre. While it is possible for the majority of human beings when they reach adolescence to keep themselves in a fairly healthy condition in such areas nobody can maintain that such a density should be tolerated in any but exceptional cases. If we follow the conditions of the child who is born in the flatted house where there is no garden or park we shall find that its condition is a very pitiable one. Until five years of age is reached the child is never out of the house except when its nurse takes it, and then it is only into the more or less contaminated air of the streets. We ought, then, to insist on limitation of the number of

houses for health reasons alone, and the only question that arises is as to a practicable method of doing this. Here we have to be very careful not to commit ourselves to something which will render it less possible to do better work in the future. The subject is so new at the present time that there is a tendency among owners of land and others who deal in it to scout the very idea of insisting on a limitation of ten or twelve houses to the acre. From Dr. Robertson's own knowledge of the essential requirements, he would say that this limit of ten or twelve houses is not excessive, and that financial and other arrangements will require to adapt themselves to such a limit in the vast majority of instances.

Within recent years he had had considerable experience in dealing with consumptives, mostly from the artisan classes. He had found that for the consumptive a shelter which consists of a roof and one screen wall to protect him from the fierce wind is quite definitely superior to a shelter with three sides and an open front so far as the cure of the patient is concerned. Anybody who has experience in dealing with these consumptives under the most unfavourable conditions can but be impressed with the extraordinarily good results which follow keeping them in the open air, and one notices the same results among the nurses who work and live in the open air. Incidentally, he feels confident that there will be a great change in the style of our dwelling-houses in the near future. Except for certain invalids, he cannot imagine any healthy person who has experienced the value of using a sleeping balcony instead of a bedroom ever going back to the closed bedroom.

Theoretically houses should each be separated from one another, but the cost of such separation is great and for economical reasons in the case of the smallest class of dwellings it is better to group ten or twelve houses per acre together—perhaps even those on several acres together—and give the remaining space as playing fields.

There is, of course, a public health aspect to the question of gardens for each individual house in addition to the economic aspect. Most working men, particularly factory workers, are greatly benefited by working in a fair-sized garden. This is not, however, a congenial form of recreation for every working-man, and therefore any regulation specifying that every house shall have its defined garden may be unnecessary. The garden attached to a house where there are only ten to the acre will, if profitably worked, produce sufficient vegetables. But whether you have a garden or a playing field you have at hand something which will enable the smallest children to develop healthfully instead of as at present in a rickety condition like many of our town children.

We need very badly a more sensitive measure of health than we use at present, viz., the death-rate. Possibly the Insurance Act and the compulsory medical inspection of school children will in time do something in the direction of giving us a better measuring apparatus for health, but anybody who is familiar with the skilled artisan classes of this country will recognise that these intelligent people are capable of great improvement in health if facilities existed. Largely their ill-health is due to the fact that they have not realised the value of an abundance of fresh air. Even to a greater extent their condition is a result of their not being

able to get a sufficient amount of fresh air from the present arrangement of buildings and the absence of open-air recreation grounds, playing fields, etc. Dr. Robertson's conclusion is that there ought to be no hesitation in adopting a limitation of, say, ten or twelve houses to the acre in the newer parts of the town.

First Stage of a Scheme.

Mr. Henry R. Aldridge deals in a very practical way with "The First Stage of a Town Planning Scheme," basing his notes on (1) the text of the Act, (2) the procedure regulations, (3) the notes of an interview—arranged by the National Housing and Town Planning Council—with the Housing and Town Planning Comptroller on special points of the regulations, and (4) the procedure actually followed by the following local authorities: the Sheffield City Council, the Chesterfield Town Council, and the Ellesmere Port and Whitby Urban District Council. Maps are included in this report, which also includes appendices giving essential extracts from the official regulations as to town planning procedure, and from the Town Planning Act. This report should prove invaluable to those who contemplate the preparation of a town planning scheme.

Second Stage of a Scheme.

Councillor Harold Shawcross, J.P., gives equally valuable guidance as to "The Second Stage of a Town Planning Scheme." The object of his paper is to state several of the problems that will arise, and to suggest various ways of solving them. Town planning schemes he considers as of two kinds—(1) That for an estate or small garden suburb usually undertaken with the consent or at the initiative of the owner or owners of the land to be planned, who will forward the plan to be adopted by the local authority; (2) the environs of a town—either all or part of them—or a large rural area which is likely to become a residential district, and which it is thought desirable to protect from ill-advised building which would be likely to destroy the amenity of the district.

Mr. Shawcross has some useful remarks on the relaxations of the by-laws or general or local statutory provisions which will probably be asked for. The first will generally be in regard to the making of roads. Most local authorities now insist on a uniform width of road, and some, in addition, a back passage for every house, all of which have to be made in the same way. As the local authority has to maintain these when they are made and taken over, they naturally insist on the best and most expensive road being put down in every case. If they made any exceptions they would be pestered by everyone building to be allowed the same exceptional treatment, and committees and officials therefore stick to the one kind of road to save trouble, annoyance, and wirepulling. Under an adopted scheme, the widths and kinds of roads need only be considered from the point of view of what is desirable for general convenience, and they will probably be fixed upon the map. The question of recovery of the cost when made can be settled by agreement with the owners who are parties to the scheme.

Other relaxations to be allowed by the local authority will be the dispensing with the back passages to houses which are required in many places. This would not be needed where the houses are built in pairs or in rows of four or six, with a passage between every other house to get to the back gardens or yards.

There could also be some relaxation of

the provision which is required in some towns for cross roads at certain distances apart. So long as communication is adequate in the opinion of the local authority this provision might be omitted altogether. The local authority could also modify the stipulation as to having the whole of back yards paved and the fencing round same with brick or stone walls which is often found in town by-laws.

In districts where special building precautions against fire are required, these might be relaxed, *e.g.* precautions as to the building of parapet walls built through the roofs to divide the houses in a row, corbels at the eaves, and some of the stricter by-laws relating to wooden frames and dormer windows; also some relaxation in the height of rooms might be allowed where the regulations insist on more than 8 ft. or 8 ft. 6 in., and also in the thickness of the walls when more than 9 in. is required by the by-laws.

In some places by-laws require the ceilings of bedrooms not to be cut into by the roof. These could be relaxed where there are fewer houses to the acre and plenty of air space. The regulation as to the open space about a house being in a particular position could also be waived, especially for corner plots.

A valuable power will be in the hands of local authorities when bargains are to be made in regard to their control over ancient footpaths and rights of way. These are often at present a hindrance to the proper development of an estate, and it should be possible to get valuable concessions in return for permitting these rights of way to be extinguished.

Such points as these having been conceded by the local authority, we have next to consider what should be insisted on in the scheme as a *quid pro quo* for the above relaxations from by-laws or statutory provisions. First as to the limitation of the number of houses per acre. This, in the kind of scheme we are considering, where there is a definite plan, need not detain us—though it would be well if all local authorities before agreeing to a scheme promoted with the good will or at the initiative of landowners, should fix a standard of the number of houses per acre, below which they would not consider any scheme at all. It should, however, be noted that if it is intended to build houses with gardens of such a size as to be worth cultivating by the tenant, that this would not be possible if more than about twelve houses to the nett acre are put upon the land.

Then the local authority should insist, where the fencing of back yard or garden with durable materials is not required, that a suitable fence or hedge is provided, to be kept in proper condition to the satisfaction of the local authority. Also to guard against houses being sold to persons who may use their premises so as to be a nuisance to the community, that a clause be inserted in the scheme that gardens shall be cultivated in a satisfactory manner and that no fowls be kept, nor animals, at less than a certain distance from dwelling houses, or where they would be a nuisance. Also that any greenhouses or outbuildings to be erected on the land should be approved by the local authority. The areas where the placing of shops should be allowed ought to be definitely fixed, and these should not be permitted elsewhere.

With respect to the proper widths that roads of various descriptions should be made and the style and kind of construction of same, the author suggests several types of roads for the various requirements of towns and rural districts.

For main traffic roads, the minimum

width of roadway should be 50 ft.; minimum width of footway, 12 ft.; minimum space dedicated, 80 ft. This would carry six lines of traffic—as, for example, a double row of tram lines and two lines of traffic on each side. For through-traffic streets, the minimum measurements suggested are:—Width of roadway, 32 ft.; width of footway, 8 ft.; space dedicated, 50 ft. This class of road would take one line of trams in crowded parts of towns and two lines in less populated parts on outskirts. It would take four lines of vehicles.

For local traffic streets, the carriage way should be 24 ft.; the footway, 6 ft.; and the minimum width dedicated 42 ft.; the houses being set back not less than 25 ft. from the centre of the road. The space to be dedicated has been fixed slightly more than the total of the minimum widths of road and footways. This has been done to meet special circumstances that may be met with, such as trees that it is wishful to preserve. In such cases it might be desirable to vary the widths of the roads a few feet. For non-traffic roads, carriage way, 16 ft.; width of footway, 4 ft.; minimum width dedicated, 30 ft.; maximum length—half a mile. Turning places for motors and vans at least every 750 ft. where there is no cross-road. Houses to be set back at least 25 ft. from centre of road.

Mr. Shawcross deals also with open spaces, recreation grounds, parks, etc., and with regard to buildings, the space about them, limitation of number of buildings per acre, their height and character. In preparing the scheme, in limiting the number per acre, it should be sufficient in the case of land that is not planned out in detail, if it be stated that the rule should be so many houses to the acre, but the requirements of the local authority would be satisfied if the average number was obtained over a certain area. A maximum number of houses, more than which should not be erected on any one area, should be stated. The local authority, in its scheme, if the scheme merely limits the number of buildings to the acre, will also have to guard against the possibility of larger buildings being erected than the ordinary house with three or four bedrooms. In residential areas the height should also be limited. Houses should not be built more than three storeys high, or more than a maximum height to be defined. Or this overcrowding could be guarded against in all town-planning schemes by a stipulation that any house, the building site of which covered more than a certain area of land, should have more open space exclusively belonging to it, or that only a certain proportion of the site should be covered with buildings. In the case of large buildings in business centres for shops, stores, offices, etc., of more than ordinary height, there should be provisions made for a certain open space around them. A convenient rule would be "that every person erecting a building should provide an open space on two sides at least equal to the height of such building measured to the top of the main wall from the ground level. A special point to be guarded against in all town-planning schemes will be the subsequent enlargement of houses by adding more rooms, etc., to them. This could be met by the suggestion made above that each house must have only a certain proportion of land exclusively belonging to it covered with buildings, or by a clause enabling the local authority to refuse additions to buildings which would interfere with the amenity of

the air space around the house. Another way would be to have a provision in a scheme that if, say, houses were allowed twelve to the acre, each house should not cover more than 600 square ft., and that no addition should be permitted afterwards of more than 10 per cent., and that any addition should be subject to the approval of the local authority.

It is considered undesirable to fix a minimum standard size of house, but that local authorities ought to have powers to enable them to regulate the number of persons who inhabit each house. It is very desirable that a standard size of rooms should be adopted, if this is possible, under a town-planning scheme. Local authorities may differ as to what the standard should be, but the following, which has been adopted at Letchworth, is inserted here as being a reasonable one and one that has worked well in practice: "Each dwelling house intended for a family must contain at least one living room having a floor area of not less than 144 square feet and containing not less than 1,080 cubic ft. of air space; it must have one bedroom having a floor area of not less than 135 square ft. and containing not less than 1,070 cubic ft. of air space; and no bedroom must contain less than 500 cubic ft. of air space."

The above might be amended in prescribing minimum dimensions for a second bedroom where there are three, as under it two small bedrooms of 500 cubic ft. might be put into a house built according to above.

The Question of Cost.

Mr. H. Lloyd Parry deals with "The Cost to Local Authorities of Town Planning Schemes." He says that the procedure Regulations issued by the Local Government Board prescribe in such complicated detail the steps to be taken in the various stages of the preparation of a scheme that at first one derives an exaggerated impression of the magnitude of the task and of the ultimate cost. It is only after a closer study of these Regulations that one appreciates how much repetition they involve and perceives that the elaborateness of the procedure is designed to meet every possible circumstance of locality. The Local Government Board have been at pains to impress the fact that the Regulations are not intended to be rigid, and that all reasonable claims for dispensing with any of the requirements will be sympathetically considered. He holds that payment of fees for expert advisers engaged for the purpose should in the general case be unnecessary. A satisfactory scheme, he says, can only be evolved by persons who have an intimate knowledge of the physical conditions of the district and the direction and strength of its industrial and residential development. A satisfactory scheme cannot be evolved upon a casual acquaintance; it needs a long and mature consideration. The permanent officials of an authority are therefore in the best position to undertake the task. It will doubtless be found necessary to supplement the official staff so as to meet the formal work involved in the inquiries as to ownerships, the serving of notices, the clerical work, and the preparation of maps, but the heads of the department should be able to undertake all that is required in the way of advising and directing. He concludes with the remark that the Housing and Town Planning Act contemplates that a scheme should be the joint product of the local authority and the landowners interested, and as the benefit contemplated is a mutual one it is mainly

on their agreements with the landowners that the authority can and should depend for the efficiency of their scheme and the avoidance of expense.

These reports, of which it would be difficult to exaggerate the practical value, are published by the National Housing and Town Planning Council, whose central office is at 18, Dulverton Road, Leicester (London office, 6, John Street, Adelphi, London, W.C.).

ANCIENT MONUMENTS.

Some that are Worthy of Preservation.

At last Thursday's meeting of the Middlesex County Council a letter was read from the Commissioners of Works inviting the Council to co-operate in the preservation of ancient monuments and historic buildings, and intimating that where the expense of preserving monuments, of national importance is heavy it might fittingly be defrayed from national rather than local resources. Acting on this suggestion, the General Purposes Committee made inquiries in the county, and now recommended that the following list of buildings, earthworks, and ancient monuments be forwarded to the Office of Works as worthy of preservation:—

THE LONDON STONE.—Said to have been placed on Lammas land at Staines about 1270, with the intention of marking the western boundary of the City of London.

HOGARTH'S HOUSE, CHISWICK.—Where Hogarth spent much of the latter part of his life, and where many of his works were produced. The house is at present in the possession of the County Council, and it contains a large collection of the artist's works.

BURY HALL, LOWER EDMONTON.—Where the death warrant of King Charles I. is believed to have been signed.

HEADSTONE GRANGE, PINNER.—Held by the Archdeacon of Richmond in 1344, and afterwards by various Archbishops as late as 1545.

GRIM'S DYKE, HARROW WEALD.—A very ancient earthwork in the grounds of the mansion of the same name.

AN OBELISK NEAR THE GROVE ESTATE, LITTLE STANMORE.—Said to mark the site of the old Roman station of Sullionacre, where Cassivellanus gained a victory over the Romans.

LAMB'S COTTAGE, EDMONTON.—In which Charles Lamb lived and died.

OLD MANSION IN PYMME'S PARK, EDMONTON.—The residence, in the days of Queen Elizabeth, of the family of the late Lord Balfour of Burleigh (the founders of the House of Cecil).

SALISBURY HOUSE, BURY STREET, EDMONTON.—Where it is reported Judge Jeffreys at one time resided.

BUILDING AT EAST END OF CHURCH STREET, EDMONTON.—In a little consulting room of which John Keats wrote all his sonnets.

MONUMENT IN ACTON PARK.—Designed as a memorial of James Radclyffe, Earl of Derwentwater, one of the leaders in the rebellion of 1715, who was taken prisoner at the battle of Preston, tried in Westminster Hall, and beheaded on Tower Hill on February 24th, 1716.

GARRICK TEMPLE, between Thames Street, Hampton, and the river.

THE OLD PIE HOUSE, WEST STREET, HARROW.—Specimen of old domestic building of uncertain date.

TOWER OF ST. MARY'S CHURCH, HORNSEY.—Supposed to be built with the stones that came from the ruins of Lodghill, upon which (in Harnesey Parke) in very ancient times stood a lodge or castle.

CROMWELL HOUSE, HIGHGATE.—Erected in the seventeenth century, probably by a member of the Springwell family. The staircase is regarded as one of the finest of its kind in the kingdom, and some of the ceilings are also of exceptional interest.

THE TREATY HOUSE, UXBRIDGE.—The venue of the Commission appointed in 1645 to endeavour to settle the struggle between Charles I. and Parliament. The Commission, consisting of sixteen Commissioners each for the King and Parliamentary party, sat at Uxbridge for three weeks, but, however, failed to arrive at any satisfactory conclusion.

Traces of Roman encampments at Heathrow, Harmondsworth, and at Shepperton.

An ancient barn on Sir Samuel Boulton's estate at Totteridge.

An ancient barn at Harmondsworth.

AGRIMENSORIAL MARKS.—Stones at Wealdstone, Whetstone, Sudbury, and Bordestone.

SAXON AND DANISH MOATS.—Camlet, Old Bury, Tottenham (three), Hanworth, Pinner, Enfield, Northolt, Alperton, Acton, Ruislip, Down Barn.

SOCIETY OF ARCHITECTS' EXAMINATIONS.

The Easter Examinations by the Society of Architects were held on April 2nd, 3rd, and 4th, in London, Manchester, Leeds, Cardiff, Birmingham, Oxford, and Dublin, the latter being a new centre. The Council have appointed Mr. A. Alban H. Scott, M.R.San.Inst., examiner in Section IV., Sanitary Science. Mr. R. Willock, F.R.I.B.A., examiner in Section III.A, was prevented by a serious illness from completing his duties, which were undertaken by the Chairman of the Board of Examiners, Professor Henry Adams, M.Inst.C.E.

The following have satisfied the Examiners:—

E. R. Bill (Shrewsbury).
W. Bradley (Bolton).
S. F. Evershed (Northampton).
W. J. Hadley (Carmarthen).
H. Lyons (Dublin).
H. E. Matthews (Yeovil).
D. J. Moss (Peckham, S.E.).
H. Phayre (Egremont, Cheshire).
G. H. Russell (Hitchin).
E. D. Sherlock (Manchester).
R. H. Syms (Isleworth).
R. Thompson (Bromsgrove).
H. A. Wilkinson (Wood Green, N.).

The following students of the Society have obtained Sectional Certificates:—

SECTION I. (ARCHITECTURE).
F. Clemes (Weston-super-Mare).
C. Ford (Reading).
W. J. Isaac (Warrington).
A. B. Johnson (Croydon).
P. Morris (Nelson).

SECTION II. (BUILDING).
W. J. Isaac (Warrington).
W. E. Kelly (London).
L. A. Reynolds (Hull).
F. J. Taylor (London).

SECTION III. (PRACTICE).
H. Best (Whitworth).
H. J. Lurcock (London).
J. Slater (Blackburn).
E. J. Williams (Leicester).

SECTION IV. (SANITATION).
J. A. Grimshaw (Accrington).
H. J. Lurcock (London).
P. Morris (Nelson).
C. F. Overy (Weston-super-Mare).
J. E. Sanders (Liverpool).
J. Slater (Blackburn).
F. J. Taylor (London).
E. J. Williams (Leicester).

THE NEW SLADE PROFESSOR AT CAMBRIDGE.

Mr. Prior's Inaugural Lecture.

Mr. Edward S. Prior, F.R.I.B.A., F.S.A., the new Slade Professor of Fine Art at Cambridge, dealt in his inaugural lecture last week with the use of the capacity of the University to organise art study.

Mr. Prior said that the programme of an archaeological and architectural school must be closely condensed for University purposes, but he believed the programme could be regulated by strictly keeping to the principles of practical art instruction and specialising to this end in the direction of the constructional arts. He emphasised that the only just education of the artist was in making him competent to meet present-day conditions, with the present-day materials of art. Mr. Prior said (as reported in the "Times") that they wanted in Cambridge continuation studies in archaeology and architecture, in which students with the bent of investigation might obtain the habits of observation and comparison on which archaeological discovery rest, and there was another special class, for whose needs a school of archaeology and architecture ought long ago to have been instituted. "The Cambridge curriculum of theology sends out to nearly half the parishes of England incumbents and curates. Many come immediately into touch with some of the finest architecture, and some of the most valuable records of art, that our island holds. Our ancient cathedrals and parish churches come under the care of Cambridge graduates, who often obtain what is practically the power of ownership to do what they will with the ancient religious art. With them lies often the decision whether the genius of ancient English art shall be preserved or destroyed. A knowledge of what is in their hands to guard and secure would seem a part of their education. The tragedy has been that the knowledge has scarcely been given, only by chance, by individual effort, or most often not at all. It is a tragedy that with the best intentions, and often with pathetic exertions to understand, clerical guardians of priceless treasures have been so ignorant (despite a University education), so unstudied in the ideas of religious art, that they have wiped out in the last century a very large part—even the greater part—of the religious art and religious antiquities that 100 years ago our churches everywhere possessed. While there are still art treasures for the Church to keep, would it not be to the advantage of the clerical vocation if clerical students took a course of historical English architecture, and understood what this meant in churches? A school of art preservation in connection with clerical training would also have its proper home in Cambridge in connection with a continuation School of Archaeology and Architecture. In most ages the religious art has been the popular art, and the artist has found his best client in the Churchman. But for the last 100 years this alliance has lost its bond. I could count on my fingers the occasions when acknowledged painters and sculptors of the English school have in the last 100 years been allowed to show their art in our cathedrals and churches. For the most part the edifices of public worship take nothing from any genuine artist. Would it not be an advantage for every candidate for orders to be given the opportunity of associating with and understanding the artist—at any rate to the extent of taking at its worth what in our churches is often degraded stuff?"

CORRESPONDENCE.

The Editors disclaim all responsibility for the statements made or opinions expressed by correspondents. Correspondents are asked to be brief, and to write on one side only of the paper.

The R.I.B.A. Elections.
To the Editor of the ARCHITECTS' AND BUILDERS' JOURNAL.

SIR,—The correspondent who, in your issue of May 22nd, signs himself “Member R.I.B.A.,” quotes from a letter written by me which appeared recently in the professional Press, and I note with pleasure that he agrees with my remarks. But he does not quote quite enough. In my letter I suggested that some information as to experience and ability should accompany the list of candidates, so that the voters might have some grounds to form an opinion upon.

As the Institute fails to give us any information, the only alternative is for the candidates to canvass for themselves and to put their own qualifications before the voters. One member has openly and boldly adopted this sensible course in the teeth of the, to me, inexplicable objections to personal canvassing which so many members appear to hold. I hope in the future other candidates will follow so good an example, and we may then see a little more energy and movement in an annual election which is now incomparably dull and sluggish.

J. H. CORAM.

To the Editor of the ARCHITECTS' AND BUILDERS' JOURNAL.

SIR,—I may point out to your evidently rather angry correspondent, “An Associate of the Institute,” that though the Council of the Institute are pledged to prepare and

try to pass a Registration Bill, individual members who take no part in the official management of the Institute are not so pledged, and many of them, like myself, look with great regret on the course which the official body of the Institute have pledged themselves to, and which has been practically forced upon them.

I had another reason for making rather a drastic protest against the circular sent out by the Institute Club. I consider the practice of sending round “caucus” circulars to try to influence the voting is a most objectionable one. It is one which I, at all events, resent very strongly.

A FELLOW OF THE INSTITUTE.

HOUSE AT WALTON HEATH, SURREY.

This house, designed for a situation close to the famous golf links, has a south-west aspect. The accompanying plans show the accommodation and arrangement of the various rooms. The elevations are rough-cast, with brick mullioned windows, the chimneys and terrace being also of small hand-made red bricks with joints left free from the trowel. The roof is covered with rough hand-made tiles with sweeping valleys. The formal part of the garden, as well as the house, has been designed by the architect, Mr. R. F. Johnston, of 11, Brook Street, Hanover Square, W.

HOUSE AT WALTON HEATH, SURREY.

R. F. JOHNSTON, ARCHITECT.

TRADE AND CRAFT.

Claridge's Asphalte.

Claridge's Patent Asphalte Co., Ltd., 21, Surrey Street, Victoria Embankment, W.C., have issued a new descriptive booklet on "The Uses and Fireproof Properties of Claridge's Patent Asphalte." The material, which has been extensively in use since 1838 for roofs, floors, damp-proof courses, linings to reservoirs, etc., is procured from the mines at Pyrimont, near Seyssel, France. In its natural state it is a bituminous limestone in which carbonate of lime and pure mineral bitumen are naturally blended in proportions varying from 7 per cent. bitumen and 93 per cent. carbonate of lime to 20 per cent. bitumen and 80 per cent. carbonate of lime. This rock asphalte is ground to a fine powder and mixed with 5 to 6 per cent. of pure bitumen similar to that contained in the natural rock; a proportion of grit is also added, and the product is run into moulds, forming blocks which weigh about 1 cwt. each, and measure about 1 ft. 6 in. by 1 ft. 3 in. by 6 in. Examples, in section, of the employment of Claridge's asphalte in the construction of standard types of fireproof roofs and floors are illustrated, as are various applications of the material to different classes of work, and the booklet, both in its text and its illustrations, is useful as well as interesting.

A Patent High-Lift Turbine Pump.

The turbine principle is now generally accepted as the ideal for primary machines, as it gives a much higher rate of speed than is possible with machines of reciprocating type, and allows of a far greater amount of work being done in much less space. Messrs. Mather and Platt, Ltd., of Park Works, Manchester, and Queen Anne's Chambers, Westminster, have issued a catalogue illustrating various types of modern turbine pumps of their manufacture. These comprise single and multiple chamber pumps, large and small, and applicable to a large variety of services—for collieries, water-works, marine, fire, and sanitary services, and in many industrial applications. The firm claim to be the original makers of the turbine pump. The first patent was taken out by Professor Osborne Reynolds in 1875, and immediately afterwards Messrs. Mather and Platt built the first Mather-Reynolds turbine pump for Owens College, Manchester, which pump can still be seen at work. The experience gained during a period of thirty years has enabled the firm to make radical improvements in the design, and, consequently, to secure the highest efficiency. The method of driving recommended is by direct-coupled electric motors, but they can also be driven by water or steam turbines, or by high-speed steam engines.

"Architects' Designs in Brass and Iron Goods."

Under this title Messrs. Swain, Verney, and Co., 22, Granville Street, Birmingham, and 46-48, Queen Anne's Chambers, Westminster, issue an illustrated catalogue, consisting of 165 large quarto pages, showing, in particular, many patterns of door, window, casement, and skylight fittings. Some of the mortice locks are shown full size, so that their construction can be examined almost as satisfactorily as by handling the actual lock, and it can be seen that they are of very superior make. Locks for all purposes are shown, and the door furniture covers a very wide range as to purpose, pattern, and mate-

rial. Door checks, door runners, floor springs and guards, and a large number of fanlight openers, casement stays, greenhouse ventilating gear, the McCabe tubular ball-bearing accordion hangers, patent folding partition fittings, and many other items, ordinary and special, are included in a comprehensive, well illustrated, and altogether interesting catalogue. Sections of it, which may be obtained separately, are those dealing respectively with the McCabe tubular ball-bearing door hangers, and with the firm's patent coin-actuated lock for use on w.c.'s, lavatories, etc., at railway stations, in public conveniences, restaurants, etc. These are made to open with halfpennies, with pennies, or with any one or two coins of almost any description, and a special doorspring prevents the door being left open by the user. There are also arrangements by which access can be had to anyone who may be taken ill when locked inside; for ensuring that the coins can be collected by two persons, as a check on possible dishonesty; and for opening the door, for cleaning, inspection, etc., without inserting a coin. The patent grip door springs are fitted with an adjustment, attached to the barrel, by means of which the strength may be increased or reduced to suit any size of door.

Warming and Ventilating Installations.

Messrs. E. H. Shorland and Brother, Ltd., of Failsworth, Manchester, report the following recent installations: Patent warm-air ventilating Manchester grates have been supplied to the Rural District Council offices, Durham; to St. John's Schools, Cardiff; and to the Carnarvon Catholic Schools; patent Manchester grates and concealed extract ventilation to the new Catholic schools at Caterham; and Shorland's double-fronted patent Manchester stoves in faience and with descending smoke flues are being installed in the extensions to the Royal Infirmary, Bristol.

Callender's Waterproofing Medium.

"Illustrated Catalogue No. 12," which has just been issued by Messrs. George M. Callender and Co., Ltd., comprises, in addition to eighteen pages of letterpress, a series of more than fifty fine half-tone process engravings, showing various works on which their pure bitumen sheeting has been used. In the text it is stated that bitumen, as distinguished from rock asphalte, came into general use about fifty years ago, and the idea of tempering pure refined bitumen and fashioning it into thin pliable sheets, "so as to obviate the costly and laborious method employed in laying rock asphalte mastic," was first conceived by the late Mr. W. O. Callender in the late 'seventies; and after many experiments the regular manufacture of Callender's pure bituminous dampcourse was begun by Callender and Sons at Millwall early in 1878. The material was first used for covering railway bridges, lining ponds, and for flat roofs, etc., about the year 1880; and it is mentioned that one of the earliest ponds lined—one at Govan, of which a charming illustration in colour is given on the cover of the booklet—was lined in 1885, and remains perfectly watertight. Callender's sheeting is entirely free from coal-tar, pitch, or any artificial product, and the special asphaltum from which it is made possesses a great range of ductility, and is tempered to suit all climates. It is supplied in rolled standard sheets, 24 ft. by 6 ft., and about 3-16 in. thick, each roll weighing about 1 3/4 cwt. Among recent adaptations of Callender's sheeting are its successful use in lining railway subways for passenger traffic, elec-

tric railways for cables and pipes, lining sewage tanks, covering cast-iron pipes laid in ground to prevent corrosion, in engineered foundations to prevent vibration, and for girder seatings. Tests made by Kirkaldy and Son, showing the behaviour of the sheeting under hydraulic pressure and under thrusting stress, are detailed, and a long list of important works, of varied character, in which the material has been used, is included in the booklet; which also contains several sectional and other sketches showing typical applications of the sheeting.

THE LONDON SOCIETY.

At the first meeting of this society, held on May 23rd at the Galleries of the Royal Society of British Artists, Pall-mall, under the presidency of Sir Aston Webb, R.A., the following elections took place: Council—Sir George Alexander, Sir J. Wolfe Barry, Sir Thomas Brock, R.A., Professor Reginald Blomfield, A.R.A., Mr. W. D. Caröe, M.A., F.S.A., Mr. J. M. Dent, Sir Alfred East, R.A., Sir Douglas Fox, Mr. Thomas Gautrey, L.C.C., Mr. C. H. St. John Hornby, Sir J. Pritchard-Jones, Bart., Mr. Philip Norman, LL.D., F.S.A., Sir E. J. Poynter, Bart., P.R.A., Sir Aston Webb, R.A., C.B., Sir Frank Short, R.A., representing the Royal Academy, Mr. Leonard Stokes, representing the R.I.B.A., Sir George Frampton, R.A., representing the Royal Society of Sculptors, and Mr. C. J. Allan, representing the Mansion House Council on Health and Housing. Executive Committee—Professor S. D. Adshead, F.R.I.B.A., and Messrs. Herbert Batsford, C. C. Bradley, Arthur Crow, T. Raffles Davison, Douglas Fox, J. Hutton Freeman, Vincent Harris, A. H. Hodge, Brook Kitchin, W. L. Lucas, D. B. Niven, Professor Beresford Pite, Messrs. G. Stevenson, Carmichael Thomas, R. G. Todd, Raymond Unwin, Paul Waterhouse, Maurice Webb, W. Willett, B. W. Young, and Thomas H. Mawson. Treasurer—Dr. S. Miall. Hon. Secretary—Mr. H. J. Leaning.

POST OFFICE BUILDINGS.

The Treasury have appointed a Departmental Committee to inquire into the system of providing Post Office buildings with particular reference to the alternative policies of renting or building, whether by the Office of Works or the Post Office. The Committee is constituted as follows: Sir F. Cawley, Bart., M.P. (chairman), W. E. Horne, Esq., M.P., H. H. Hambling, Esq., J. Slater, Esq., F.R.I.B.A., Howell Thomas, Esq., F.S.I. The Secretary is L. C. Bromley, Esq., of the Treasury.

Mr. Henry Herbert Hambling is general manager of the London and South-Western Bank. The bank has about 200 branches in London and elsewhere, and its policy has always been distinctly in the direction of acquiring the absolute title to the premises used in its business. Mr. W. E. Horne, M.P., is the president of the Surveyors' Institution, and a director of the Prudential Assurance Co., Ltd. He has represented the Guildford Division of Surrey since 1910. Mr. John Slater, F.R.I.B.A., is surveyor to the Berners estate in Margate. He was president of the Architectural Association in 1887, and vice-president of the Royal Institute of British Architects from 1900 to 1904. He is also a member of the Tribunal of Appeal under the London Building Acts. Mr. C. J. Howell Thomas, F.S.I., is one of the principal valuers in the Inland Revenue Department at Somerset House.

THE ART OF THE PLASTERER.*

BY GEORGE P. BANKART.

MR. BANKART said that he should confine his remarks to an analysis of principles and qualities essential in good plaster decoration. The chief point he wanted to emphasise was that in whatsoever age the art of the plasterer was practised the greatest result was attained by the proper use and development of the particular kind of plaster employed. The many ways of modelling and handling decorative work were due almost entirely to the difference in the nature of the plaster that was used. He would classify these plasters into four distinct headings: First, the "stucco-duro" of the Italians (of carbonate of lime), *i.e.*, the "limestone" of the hills, which was very carefully selected, thoroughly well burnt, and slaked for many years; thumped, chopped, and knocked about, and so toughened that it became very flexible and malleable—so malleable and delicate, in fact, that the die-sinkers used it in preference to wax. Another division was the "parge-work," or the ordinary lime, sand, and hair plaster used for parging flues, differing from the ordinary lime plaster in that it contained road scrapings, cow dung, and ox hair. The third division was "plaster of Paris," or sulphate of lime, which was introduced into this country in the reign of Henry VII., although in general it was not much used until Elizabeth's time. Then there was the modern process of casting in fibrous plaster from jelly moulds.

Stucco-duro.

The use of "stucco-duro" was known so far back as 3500 B.C. In Italy it had been exhumed in the early part of the sixteenth century, and on some of the tombs in Rome executed in the first half of the century could be distinctly seen the incised marks of the metal tool. This work was modelled *in situ*, and was not intended to be seen by daylight; consequently, perhaps, imperfections were excusable, but the work, which was coloured, was very fine and wonderful for all that.

Later, a band of artists trained by Raphael executed much work in Italy and France. Troubles followed in Italy, and this band of artists, in escaping from Rome, became scattered. Some went to Florence, some to Venice, and others to Mantua. A school of "stuccatori" modellers was founded in each place. The art spread all over Italy, and from there to France, where Primaticcio decorated Fontainebleau for François I. This, however, was by no means the first stucco work executed in France.

The first "stucco-duro" work in England was carried out at Nonsuch Palace, on the hill between Epsom and Cheam, Surrey, from where the art, fostered by the Italians, spread sooner or later to Longleat. An English plasterer named Charles Williams, who had modelled at Nonsuch and travelled in Italy, carried out the Longleat work and that on the walls of the Giants' Chamber, etc., in the first Hardwick Hall; this work was of very simple character. In the later hall the frieze in the Throne (4 ft. 6 in. deep) was done by men trained by Charles Williams, and coloured in tempera. The leaves were simply dabbed on in large groups and shaped with a small metal tool or trowel and slightly undercut at the same

time. They were done very quickly and simply; sometimes the birds and animals were painted on the groundwork instead of being modelled. It was found that the material could only be procured with difficulty and inconvenience in those days in this country, because of the marble dust and other ingredients that were necessary.

Parge-Plasterwork.

The art did not live long in the hands of the English plasterers after the Italian fashion, the Englishmen keeping to their parge-plaster and developing an art of their own. The first development in the English plaster ceilings was in the form of very simple panellings formed by beaded mouldings, with little bits of sprigs of modelling stuck at the mitres and angles, and with rosettes, etc., in the panels. Then they added simple rounded mouldings, and this practice gradually grew until they covered the ceiling all over with a repeating arrangement of panellings. This sort of thing continued to develop by degrees, and, although the modelling was exceedingly simple, the work of this period was perhaps the purest and most English. The leaves nearly all took a slight concave form, with now and again convex lumps of flowers, fruit, bosses, and heraldic bearings and devices. Exterior parge work was done practically all over the country, and in London particularly, up to the time of the Great Fire of 1666. The timber construction of the buildings was covered mostly all over with this parge-plaster ornamentation. The plaster was as tough as leather, and weather-proof. Old engravings of London pageants and street processions show the work very clearly. The work was of a simple type, put on with a trowel *in situ*, in panellings, flowerings, in between and under windows, across beams, and in gables and oriel coves. Many examples had been much filled up with whitewash. One very interesting feature about this parge work was that in Essex, Norfolk, and Suffolk (particularly Norfolk and Suffolk) one could pass through various districts and every few miles mark quite a distinct change and type of work, showing that it was done by the native and local plasterer or "dauber," or perhaps mason. They worked in their own little radius and had their own set of patterns, which they varied.

Some Old Examples.

With respect to the Elizabethan period there was an example in Burton Agnes, Yorks, to which special attention was called. The work was from a semicircular vault once existing in Burton Agnes Hall, long since perished. It was of modelled scrolls of roses, done *in situ* and coloured. This was one of the most beautiful bits of modelling in this country. There was only a small portion of it left.

Many slides were shown illustrating in great detail the drawing-room ceiling at Speak Hall, Lancs, where there were many panels between the beams, all different in design. Each panel was different in detail and type of flower. Several interesting examples were shown of ceilings in which the stem work was modelled direct into the ceiling, partly pressed with a die or stamp, and partly cast and stuck up so far as the flowers and lumps were concerned, including work from Kellie Castle, Fifehire. Attention was especially drawn to the resource of the builder or

architect in taking advantage of the opportunity given by the rooms formed in the roof space, and the quaint constructional developments afforded by this means. Slides were shown of the flat ceiling of Queen Victoria's bedroom at Holyrood Palace, Edinburgh. The ceiling of this room was formed centrally into a large square panel by a moulding bound round by a belt of leafage and fruit modelled and cast in individual members, and stuck up leaf by leaf and fruit by fruit in a continuous growth of decorative rhythm. Bounding the large central square panel at the cardinal points were four circles of leafage similarly modelled, dividing four V-shaped panels filled with straggling stem work, modelled *in situ*, and vine or oak-like leafage, cast separately and stuck up loosely in one rich filling.

Revival of Stucco-duro.

The lecturer then went on to describe and illustrate the revival of stucco-duro in modelled ceilings of the periods of Inigo Jones, Webb, and Wren by the Italian plasterers, who wore goggles to protect their eyes from the falling fragments of lime stucco which they used. Fine examples were shown from Coles Park, Ashburnham House, Westminster, Holyrood Palace, Belton House, Melton Constable, Acklam Hall, Brickwell House, Grantham House, Groombridge Place, and elsewhere, illustrating the beauty and technical value of stucco-duro as a material for working *in situ*. In all these examples it was explained how the quality of the material, which could be regulated in the setting to any degree of time by the introduction of various ingredients, enabled the modellers to give sharpness of edge, thinness of substance, and depth of undercutting and relief to any extent; how the flower heads stuck out from the bulk and were attached by isolated stalks steeped in the same "plaster"; how in some cases the stem work corkscrewed round and round the highly relieved lengths and garlands of modelling, and how the leaves and flowers could be modelled as thin in substance as the petals of a rose or a piece of drawing paper. The secret of the beauty of this work was due to the employment of a particular plaster material and process that had not been available in modern times, the composition and manipulation having been lost sight of for two centuries until now. The plaster used for this work was the material spoken of at length by Vitruvius in his writings on architecture, *viz.*, very carefully selected lime, which has been slaked for many years, mixed with finely sieved marble dust and various ingredients to regulate the setting as required according to the thickness of the plaster or the size of the work. The plaster, which was worked in the fingers or with the steel trowel, was very fine and smooth, intensely sensitive, and impressionable to the touch of the modeller. It has a fine reflective quality possessed by no other plaster, can be worked very thinly and delicately, and dries out very hard.

Twelve years ago, when the famous ceiling at Kilmainham Hospital, Dublin, was taken down and remade owing to its dangerous condition, the modelled detail had to be reproduced in compressed *papier maché*, because the art of making the old stucco-duro plaster, of which the original ceiling was composed, was lost, and the material was thought to be unobtainable. Detail thus wrought and built up in the fingers of the modeller could not be reproduced by casting in any material or by any mechanical process whatsoever. The art of stucco working in these islands died

* Extracts from a paper read before the Edinburgh Architectural Association.

just before the introduction of the composition by the Brothers Adam, and during the last eighty years this has been replaced, chiefly by the mechanical reproduction (in fibrous plaster cast from jelly moulds) of clay modelled decoration based largely on the lines and spirit of the stucco work (erroneously known as Georgian) done under Inigo Jones, Wren, and others.

Discovery of an Old Method.

This old stucco-duro material was now to be had, the secret so far being the lecturer's own; several large ceilings were now being worked in exactly the same Italian stucco-duro material and process as famous ceilings to which reference had been made. Another process was that of modelling the leaves, fruit, flowers, etc., individually, casting them separately in plaster of Paris or Keen's cement, and tucking them up into a prepared hollow ground work *in situ* on the ceiling. Even this would not give the same beauty of definition; but it was the next best thing and required the judgment and arrangement of an artist not always forthcoming in the purely mechanical training of the modern plasterer, although there were signs of considerable ability in this direction. A few examples of Wren's later work were shown in which the Dutch modellers re-introduced for a time the French type of work very indifferently; also the work of Hawksmoor, Archer, Talman, and others. The Brothers Adam took their inspiration from the Pompeian masterpieces and gave these islands some splendid examples of artistic plasterwork in a plaster composition in which they were financially interested. Then followed that degrading period of so-called pseudo-Classicism in which the London squares and streets, and also the provincial towns, revelled for a time, creating a prejudice that, with a large proportion of the general public (and even amongst some architects), had lasted to the present day, and had done so much to retard any real development of the plasterer's art.

The Trend of Modern Work.

Mr. Bankart then passed on to modern

materials and modern work, showing by illustrations that a considerable amount of work had been done by living journeymen plasterers who, by diligence and careful study, had picked up the threads of past traditional methods of working and applied that knowledge to modern materials and modern construction with considerable ability and success as artists as well as mechanics. This, he maintained, was at last a favourable sign and gave bright hope of the foundation of a new living school of decorative plastering. The fault was not the plasterers', but the natural misfortune of their dull training for generations back in being left to think that mechanical accuracy and perfection of surface was the zenith of plasterers' work.

Much good and interesting plasterwork was being done in different parts of the country, and there was every encouragement for the younger generation of plasterers to study and take up the once living art of their trade and to develop it in a manner suitable to and worthy of our modern methods of construction.

THE "PERFECT" SYSTEM OF HEATING.

When it is proposed to equip a building with a heating installation, the considerations that will most affect the choice of a system are simplicity of action, general efficiency, with the minimum amount of attention and economy of upkeep. A system of heating that complies with all these conditions is the "Perfect" system of Messrs. Benham and Sons, Ltd., 66, Wigmore Street, London, W. This system involves no trouble in management; the fuel having been supplied to the boiler, the apparatus may be safely left to distribute its heat evenly and at a uniform rate throughout the whole building. No complicated machinery being employed, skilled knowledge is rendered wholly unnecessary. An important feature of the "Perfect" system is the circulator placed on the return main of the apparatus alongside the boiler. This circulator,

which is patented, can be worked by an electric motor, hot air, or a petrol engine. The cost of working the motor is more than covered by the saving of fuel effected in its use. Therefore it is cheaper to heat a building with the circulator in action than with it shut off.

The circulating pipes used in the "Perfect" system are of remarkably small diameter, the consequent advantages being neatness of appearance, minimum wastage of heat in circulating mains, saving of fuel for heating up the apparatus, and decreased builders' work when the original installation is made. Another advantage is that the circulating pipes and connections can be run irrespective of levels. The circulations may be run in any direction desired—overhead, underneath, up and down—in fact, in any way that the peculiarities of a building may render necessary. The accompanying diagram illustrates the possibilities of the "Perfect" system in this respect.

The pipes may be concealed in skirtings, floors, ceiling spaces, or chases, or may be conveniently run in the open since there is nothing unsightly in their appearance. No excavation is necessary for the boiler-house, as the boiler can be fixed upon any floor.

With the "Perfect" system a temperature of from 180 deg. to 190 deg. F. can be obtained on the radiators. The system can be fixed to existing installations which may have become unsatisfactory; these may thereby be made effective and efficient at a very low cost. The principal advantages of the "Perfect" system are that there are no intricate parts to get out of order and no maze of pipes in the boiler-house requiring the expert attention of an engineer. Another important consideration is that the fire may be banked up over-night or during the day without in any way interfering with the working of the installation.

In the "Perfect" system the temperature of the water in the boiler is immaterial; it may be allowed to drop down to 100 deg. F., or lower if desired. When the fires are banked at night the circulator should be shut off and the by-pass valve opened, the system then working as a gravity one. The whole apparatus required for working the system is confined within a small space in the boiler-house.

Messrs. Benham and Sons, Ltd., have installed a large number of "Perfect" systems throughout the country with highly satisfactory results. Arrangements would be made, if desired, for the inspection of an apparatus under actual working conditions.

AN EXTENSIVE BUILDING SCHEME.

One of the most extensive house-building schemes ever carried out in Scotland was completed last week at Port Glasgow. This is what is known locally as the reconstruction of the "Bay Area" of the town. The work, which was started three years ago, was initiated by the late Mr. W. T. Lithgow, principal partner in the firm of Messrs. Russell and Co., shipbuilders. He contributed £10,000 towards the cost, and also presented the ground to the Town Council. The total expenditure has been about £100,000. The buildings consist of forty-six large dwelling-house blocks, with accommodation for 400 families and forty-four shops. The houses have one, two, three, and four apartments, and they take the place of what was an area of the pronounced slum type.

"The Newer Responsibilities of Architects."

THE above title given to the paper read by Mr. Woodward at the Institute meeting on June 3rd (as reported elsewhere in this issue) must have been suggested by the fact that it was in some respects intended as a continuation of the class of subjects previously treated in two or three papers by other members under the same heading; otherwise the title of the paper was the only illogical thing about it, for, except in regard to one point, it hardly dealt with new responsibilities so much as with old points which have been somewhat neglected, or on which rather confused ideas seem to prevail.

The one point mentioned in the paper in regard to which there are some newer responsibilities for architects is that of modern hurry in building, and on that point Mr. Woodward spoke very forcibly and well, though he touched only one side of the subject. The results, he said, of the modern effort to hurry up buildings (for commercial reasons) are that architect and builder are made responsible for defects which would not arise if a proper amount of time were allowed, first, for the studious preparation of the drawings and specifications; and, secondly, for an adequate time to build properly, allowing a sufficient time between the trades for the work to approach some sort of dryness. All this is perfectly true; and it is, indirectly, the public, the clients, who are to blame for a good deal of bad building, because they will have structures built in a shorter time than it is possible to do them well. The rage for hurry in the present day is responsible for many evils. We heard the remark from a naval officer that it was really the public who were responsible for the Titanic disaster; they will be carried in the shortest possible time, and they will patronise the line which makes a trip in a few hours less time than another, without any consideration of safety. It is somewhat the same with building; the public insist on a building being finished in a shorter time than is fairly possible, and then the architect or contractor, or both, are blamed if the building shows structural or practical defects.

That is bad enough, and no doubt it often results in great unfairness to the architect, and may be characterised as a newer responsibility. But there is the still more important point, the effect which this hurry-scurry system has not merely upon the architect, but upon architecture. No great architecture was ever done in a hurry. Architectural design, to be worth the name, requires careful study and consideration, both of general composition and of every detail. What time is there for that now, in forty-nine cases out of fifty? The result is that architecture is produced on the popular pattern of the moment. At present the popular pattern consists in leaving unmeaning blocks of masonry, what may be called panels in relief, all over a building, with vertical festoons depending from them like sausages. All over London one finds that kind of detail in new buildings.

There is no meaning and no thought in it; but it is the fashion of the moment, and there are plenty of clever draughtsmen ready to knock off an elevation on this pattern in double-quick time. But that is not architectural design.

To the personal matters in connection with the case which Mr. Woodward took as the text for his paper we have no intention of referring here; but the judgment of the Official Referee raised general considerations which are of some importance. In the first place, he seems to have decided that Clause 3 of the Institute Form of Agreement, which provides as to the course to be followed if another architect is appointed during the progress of the work, is legally inoperative, as the architect, being the one agreed upon in the contract between employer and contractor, cannot be dismissed by one of the parties to the contract without the consent of the other (the contractor). In common sense, as apart from law, such a position is, of course, ridiculous. The idea that a client cannot dismiss an architect who is his professional adviser, and with whom he is dissatisfied, without the permission of the contractor who is carrying out the building, and who is really his employee, seems too preposterous for anyone but a lawyer to entertain; but if that is the legal effect of Clause 3 of the Institute Form of Agreement, it ought to be altered in its wording without delay, so as to do away with such an anomaly.

The judgment in the case referred to included observations which seem to amount to a caution on the subject of the nature of the authority delegated to a clerk of works. Most architects and most clerks of works probably thoroughly understand that the clerk of works' duty is to see that the architect's orders are carried out, and the conditions of contract as to materials and workmanship insisted on. The Official Referee pointed out that a clerk of works could have no authority to relieve the contractor from any of the obligations on these points provided under Clause 7 of the Institute Schedule of Conditions of Contract. That, of course, is perfectly plain; he could only report to the architect and ask for orders, and those orders should be in writing, both to the clerk of works and the contractor. It would be no defence for a contractor who had used inferior materials to plead that he had the permission of the clerk of works, because the latter has in himself no power to give such permission. But if things are to be put on a perfectly legal basis, there might come in the question, Has the architect any legal right either to consent to the use of inferior materials, or to order extras, without consulting his client, who is one of the parties to the contract? He could only legally have that power if he had a written agreement, as between himself and his client, that he was to have power to alter materials or to order extras, on his own judgment, if he considered it in the best interests of his client to do so. In the case of such a written agreement the client would be bound to agree to the altered materials, or to pay the bill for the extras.

Probably there are not many clients who would be content to give such a free hand to their architects, deliberately and in writing; and perhaps there are not many architects to whom it would be safe to give it, not

from any question of their probity, but of their judgment. But there is no doubt that in many cases clients do put their architects in this position, not by an agreement in writing, but by leaving everything in their hands and having perfect confidence in them—until the bill of extras comes in, and then they think themselves very ill-used. This *casus belli* between client and architect has cropped up over and over again. In some cases the architect has been to blame in allowing too free a hand in extras, perhaps partly for his own satisfaction in his building, but in a majority of cases he has really been acting for the good of his client. The grievance of the client always is that "he did not know" of any of these extras; he was prepared to pay the contract price cheerfully, but he grumbles at finding a number of little (or sometimes large) extra charges for things he knew nothing of. And the complaint is, from his point of view, reasonable. The moral (for the architect) is a two-fold one. First, never allow extras without your order in writing; nothing is more likely to make trouble than concessions or orders made on the spur of the moment in a verbal form. This may seem too self-evident to need remark, but cases have occurred (*causes célèbres*, some of them) in which extensive verbal permissions have been given by the architect, and have brought disastrous consequences afterwards. Secondly, it is necessary either to have a written agreement with the client that he leaves alterations to the architect's judgment, or he should be informed in writing, and in a copied letter, every time an extra is ordered. An observance of these rules would have prevented many a legal action between client and architect. And these are not "newer responsibilities," or ought not to be.

The R.I.B.A. Elections.

BY the courtesy of the R.I.B.A., we give the results of the elections of officers and council for the session 1912-13, which were announced at last Monday's meeting as follows:—*President*: Reginald Blomfield. *Vice-Presidents*: A. W. S. Cross, E. Guy Dawber, George Hubbard, Ernest Newton. *Hon. Secretary*: Henry T. Hare. *Representatives of Allied Societies*: C. E. Bateman (Birmingham), John Brooke (Manchester), Arthur Clyne (Aberdeen), J. A. Gotch (Northamptonshire), G. Hastwell Grayson (Liverpool), William Milburn (Northern A.A.), A. N. Paterson (Glasgow), E. R. E. Sutton (Nottingham), A. L. Campbell (Edinburgh). *Members of Council*: A. W. Brewill, Max Clarke, T. E. Cooper, William Dunn, F. R. Farrow, William Flockhart, W. A. Forsyth, J. S. Gibson, H. V. Lanchester, C. S. Peach, Sydney Perks, S. P. Pick, C. H. B. Quennell, E. A. Rickards, W. J. Tapper, W. H. White, E. W. Wimperis, William Woodward. *Associate Members of Council*: K. Gammell, S. K. Greenslade, Edwin Gunn, A. E. Munby, Septimus Warwick, A. Needham Wilson. *Representative of the Architectural Association*: Gerald C. Horsley. *Auditors*: John Hudson; W. H. Burt. *Art Standing Committee (Fellows)*: E. Guy Dawber, William Flockhart, Henry T. Hare, Gerald C. Horsley, T. G. Lucas, Ernest Newton, E. A. Rickards, J. W. Simpson, H. H. Statham, W. J. Tapper; (*Associates*): O. Maxwell Ayrton, Matthew J. Dawson, Sidney K. Greenslade, J. J. Joass, Septimus Warwick, A. Needham Wilson. *Literature Standing Committee (Fellows)*: J. Alfred Gotch, W. Curtis Green, D. Barclay Niven, G. H. Fellowes Prynne, F. M. Simpson, R. Phené Spiers, C. S. Spooner, C. Harrison Townsend, E. P. Warren, Paul Waterhouse; (*Associates*): Walter Millard, Herbert Passmore, C. Wontner Smith, A. J. Stratton, W. H. Ward, H. W. Wills. *Practice Standing Committee (Fellows)*: Walter Cave, Max Clarke, A. W. S. Cross, George Hubbard, J. B. Mitchell-Withers, C. Stanley Peach, Sydney Perks, H. D. Searles-Wood, A. Saxon Snell, W. Henry White, William Woodward; (*Associates*): Horace W. Cubitt, K. Gammell, Edward Greenop, J. Nixon Horsfield, C. E. Hutchinson, Herbert Shepherd. *Science Standing Committee (Fellows)*: H. Percy Adams, E. R. Barrow, W. E.

V. Crompton, Bernard J. Dicksee, William Dunn, F. R. Farrow, Ernest Flint, Horace Gilbert, George Hornblower, R. Elsey Smith; (*Associates*): R. J. Angel, G. Leonard Elkington, Charles J. Marshall, Alan E. Munby, D. L. Solomon, E. W. M. Wonnacott.

In Committee of Supply.

THE discussions in the House of Commons under the head "Committee of Supply" are often interesting, and sometimes amusing. They afford an opportunity for the discussion of various points connected with the architectural treatment of London, and they also give us glimpses into the minds of our representative legislators in regard to artistic subjects; glimpses, however, which do not always tend, in Wordsworth's phrase, to "make us less forlorn." The general tendency is to object to all expenditure on architecture or other forms of art and to find out that everything that has been done or proposed is wrong.

The first subject that came up in "Supply" on June 4th was that of "Diplomatic and Consular buildings," in regard to which the Government seem to have been very rightly moved by the idea that such buildings abroad should be kept up to a standard suitable to the dignity of the nation. A sum of £6,000 is to be spent on providing a reception room for the Agency house at Cairo, on the ground that "the house which the British Agent occupied must be suitable to the dignity of his position in Egypt." Could anything be more reasonable? Then there is a sum of £20,000 for rebuilding the Embassy house at Therapia, which, it appears, had been burned down. One can hardly suppose that an Embassy house worthy of the nation could be built for less; but this also was the subject of attack!

There turned up the rather more difficult question of the Edward VII. Memorial in the Green Park, on which there is some excuse for differences of opinion. That the Memorial turns its back to the main thoroughfare is certainly unfortunate, but it was of paramount suitability that it should face towards the Victoria Memorial, and a memorial statue cannot be made to act the part of Mr. Facing-Both-Ways in the "Pilgrim's Progress." That the monument as a whole will make a very large intrusion on the green space of the park—larger than was really necessary—is true; but one of the speakers who thought so nevertheless said that he would regard the controversy as closed. It will, at all events, be a better memorial than the Victoria one, in a general sense, because the sculptor has not in this case been permitted to be his own architect, and a very gifted architect has been commissioned to carry out the general design. But what one must protest against is the demand made by two members, Captain Murray and Mr. Whitehouse, that the Office of Works should give an undertaking not to put any more sculpture in the public parks! A more ridiculous prejudice could not be imagined. One of the means of beautifying and giving interest to public gardens and parks is the erection of sculpture in them, and they afford the most favourable conditions for placing open-air sculpture with effect; sculpture goes exceedingly well with foliage and it adds to the interest of a garden. Look at Versailles, and the Tuileries Gardens, and the Luxembourg Gardens, all full of fine sculpture. Are they spoiled for enjoyment by it?

Then the members entered on another dispute in regard to the proposed lighting of the House with electric light. On the question of which kind of light, that or gas, is the most agreeable to work under, there will of course be differences of opinion; but we should advise the members who oppose the introduction of electric light to reconsider their opinions. They will probably find the electric light more satisfactory on the whole, as a light, and it has the great advantage of not contributing impurity to the air of the House. There was also, of course, the member (there is always one) who complained of the ventilation of the House; but Lord Balcarras was probably correct in saying that the ventilation of the House of Commons is better than that of any other place

of public assembly; it is certain that quite exceptional pains have been taken to make it so.

On June 5th Committee of Supply was mainly occupied with the very large question of housing in rural districts, various members challenging the President of the Local Government Board to explain to them why it was that so little had been done to put the Housing and Town Planning Act into operation. The evidence given as to the present bad state of rural cottages, and the absolute dearth of accommodation of any kind in many districts, was as decisive and unanswerable as ever on that subject, and no effectual remedy has been proposed. Mr. Burns said, however, in reply, that the amount of loans sanctioned to local authorities for housing improvements did not by any means represent all that had been done, as what had been done by private enterprise was seventy or eighty times more than what local authorities had attempted. Nevertheless, the revelations made in the course of the debate, by members living in and representing populous country districts, leave a most serious impression of the dreadful lack of decent house accommodation in many parts of rural England. It almost seems that if the rebuilding of country cottages and the supply of new ones (for quantity seems as deficient as quality) cannot be made the interest of any capitalists, it may have to be taken up by the State, as a remedy for an evil which may indirectly injure the whole community.

By-laws in Rural Districts.

SOME foolish business was done in one of the Standing Committees of the House of Commons last week, when a successful effort was made to relax the conditions as to building by-laws in the Housing of the Working Classes Bill. The Government had already proposed a certain degree of relaxation, in the shape of an amendment which was to exempt from the operation of the by-laws schemes promoted by a local authority under certain prescribed conditions where the plans were approved by the Local Government Board. But Sir R. Baker moved a further amendment with the object of extending the exemption to any schemes promoted by private persons where at least six houses were to be erected. With regard to this we would say that the object of building by-laws is to secure that houses, including cottage property, should be properly and soundly constructed; yet, according to the amendment, a private person who would have to observe the by-laws if he built one cottage might be at liberty to build half-a-dozen just as he pleased. As Mr. John Burns pointed out, a very probable result would be that a man would come forward with a scheme for building six houses in order to obtain exemption, and then would only build one or two. Mr. Burns also proceeded to show that building by-laws were not what prevented cottage building, as it was a curious fact that in 189 rural districts where there were no by-laws there was less building than where there were by-laws; and he added, with plain-spoken truth, that they had no right, in the name of helping rural housing, to run the risk of covering the countryside with cheap and nasty buildings by wholesale exemptions from the by-laws. He is absolutely right, and his arguments ought to have been conclusive; the mover of the amendment, who evidently was afraid of hearing any more, moved the closure of the debate, and this was stated to be carried by 16 to 14, although the chairman admitted afterwards that under standing orders the closure could only be carried if at least 20 members voted for it; and the closure being thus illegally voted, and the voice of common-sense stopped, the absurd amendment was carried by the same majority of 16 to 14. It may possibly come to nothing, for Mr. Thorne, the Vice-President of the Municipal Corporations Association, declared that no local authority in the country, when they came to know the bearings of the Committee's decision, would tolerate it for a moment, and that the probable result would be that it would wreck the Bill. It is a proceeding any-

thing but creditable to the Committee which lent themselves to it. All this nonsense of encouraging people to build on the promise that if they will only build plentifully they shall build as badly and cheaply as they like, is the natural outcome of the cry that has been got up against rural by-laws by the editors of certain weekly papers. Building by-laws, though it is no doubt difficult to frame them so as to be equally applicable to all circumstances, are absolutely necessary, in order to ensure against flimsy building, which in the long run is a way of doing more harm than good to the rural districts.

Competition Designs for Mural Painting.

IN the restored Crosby Hall on the Chelsea Embankment (a place rather inconveniently inaccessible) there is a collection of designs for mural paintings to be executed in schools and other establishments, for which prizes have been offered by a committee interested in promoting this class of decoration. With every sympathy for the motives which led to this undertaking, we cannot think that the results are very promising. Probably experienced artists would hardly compete for these prizes, and the designs exhibited are for the most part crude in idea and in many cases not at all well drawn. This fact is the more emphasised by contrast with a good many designs by able decorative artists, the late Albert Moore and others, which are also included in the exhibition. Decorative mural painting, with its severe restriction in regard to style, above all things demands mastery in drawing, and that is just the quality which is not present in most of the designs submitted in competition. Among the best are some on the subject of the Nativity, intended for a church; the best is perhaps a very mediæval one in style, with the odd signature, "O tempora Mores," apparently an imperfect recollection of the celebrated sentence of Cicero, "O tempora! O mores!" A design by "Huldre" illustrating "Picking Strawberries," and intended for Messrs. Crosse and Blackwell's jam factory, has merit, especially in the detail figure of the boy. But there are very few of the designs which we should think really worth executing in permanent form; and in some cases the suitability of the subject may be questioned. There are some clever sketches, for instance, intended also for Messrs. Crosse and Blackwell's factory, representing girls engaged in operations of the factory; but where is the sense of painting on the walls a conventionalised representation of the persons employed and the processes actually going on in the building? A decorative painting should rather take one away from the mere prose fact of the operations than provide a conventionalised repetition of them. There is rather a sense of unreality in the whole show; the intention is very good, but the result is disappointing. The best things there were among the slighter attempts; a wall panel, for instance, of an Australian landscape, by Miss Merfield, and three or four patterns for dado borders, under various signatures. But we fear the more ambitious subjects are rather failures.

"The Amalgamated Building Workers' Union."

A SPECIAL committee appointed by the Trade Union Congress Parliamentary Committee to inquire into the advisability of amalgamating all the unions in the building industry into one solid body has presented its report, which is entirely favourable to the project of organisation "by industry instead of craft." More industry and less craft is precisely "What the Building Trade Wants," but it is hardly likely to get it from the new movement. More industry than harmony can be pretty confidently predicted for the special conference which is to be held in London on June 21st to arrange "the final details" (finely optimistic phrase!) of the amalgamation. Twenty unions, we read, are definitely committed to the scheme; and it is proposed that there shall be a uniform scale of benefits and contributions—from which it would appear that there are

to be no invidious distinctions: the labourer with his sixpence or sevenpence an hour is not to be austere debarred from paying as much as the skilled worker at tenpence or a shilling. It looks like a typical democratic proposition; but will not the labourer shrink sensitively from the undeserved honour of equal contributions from unequal wages? Or is it in contemplation to secure all-round equality and fraternity by levelling up wages to a uniform figure? A strong argument (trade-union brand) for this course would be that it would effect enormous economies in simplifying the employing builder's accounts. In some respects the amalgamation would afford welcome relief to the federated employers, who are themselves rather eclectically constituted. It ought to simplify procedure in cases of dispute. United Labour, it may be supposed, would no longer speak to the employers' federation spasmodically, and in various and discordant voices. Among brethren dwelling together in unity, the plasterers, for instance, could not consistently resume their old-time amusement of straight-way upsetting an amicable settlement between the employers and the bricklayers; and the interesting if somewhat wearisomely reiterated demarcation squabbles of smith versus plumber, or of slater versus tiler, need no longer vex the soul of the inoffensive employer, since surely these little differences would, under the new régime, be quietly and comfortably settled within the greatly amplified circumference of the happy-family circle. It is to be feared, however, that the basic idea of amalgamation is not to relieve the pressure on employers, but to add to it all the dynamic force of united and simultaneous effort. It is not peace, but war. Yet amalgamation and unanimity are so far separate and independent entities that the latter is not an essential sequence to the former; and on scrutinising the list of the twenty unions which are attempting coalition, it is difficult to believe that so many diverse, not to say antagonistic, interests can ever be reconciled and tempered to harmonious agreement and united action. Consequently, although the proposed amalgamation may be arranged—which, even yet, is by no means a foregone conclusion—there will remain the possibility that the internal jealousies and antipathies from which the separate unions are not free will be intensified enormously by the clash of interests that seems inevitable. It is the clash of interests that has suggested amalgamation; and the attempt to bring them closer together may easily mean more clash.

The Ownership of Plans.

POPULAR misconceptions of the law, like other traditions, good and bad, die very hard. There are still those who believe that plans always remain the property of the architect who made them. Thus, a correspondent of the "Hospital," writing to that periodical on an architectural subject, concludes his letter with this confident pronouncement: "Your article is somewhat misleading on the subject of the ownership of drawings. They are usually reputed to be the property of the architect, and not of the employer, and this view has, I think, been upheld by a test case." Unfortunately there can be no doubt that the drawings "are usually reputed to be the property of the architect." That, however, is a popular misconception, and its hardy survival justifies a further attempt to explain the position. In the leading case in which the matter was determined, the decision was the reverse of that alleged by the correspondent of the "Hospital." The case in point was that of *Gibbon v. Pease*, which was heard by Collins, M.R., Mathew, L.J., and Cozens-Hardy, L.J., constituting the Court of Appeal of the Supreme Court of Judicature, on March 24, 1905, when, following the precedent set in *Ebdy v. McGowan*, the Court decided that "a building owner who employs an architect to carry out work upon the ordinary terms of paying him 5 per cent. on the contract price, is entitled to the plans and specifications prepared

by the architect for the purpose of carrying out the work, after the work is completed and the remuneration paid. An alleged custom to the contrary would be unreasonable and bad." The plaintiff was the owner of certain houses in Bayswater, which he desired to convert into flats. Defendant having prepared the necessary drawings and superintended the execution of the work, refused to hand over the plans and specifications upon the demand of the plaintiff, who thereupon brought an action for their recovery. Ridley, J., following the judgment in *Ebdy v. McGowan*, refused to admit evidence of any custom of the profession that the drawings remained the property of the architect, and he held that the building owner was entitled to recover them. Against this judgment the architect unsuccessfully appealed, the Appeal judges being unanimously agreed that, in the absence of any stipulation to the contrary, the drawings became the property of the building owner, and they were all of opinion that any custom of the profession that vested in the architect the ownership of the drawings would be unreasonable. Counsel for the architect contended that "the essence of the contract between the client and the architect is only that certain work is to be done and carried out for the client under the superintendence of the architect, and not that anything shall be made and given to the client," but this contention has never succeeded, although to a layman it looks like equity, the opposite view being based upon analogies that are not conspicuously apt—such as that "a solicitor upon being paid his bill was bound to deliver up to his client drafts and copies of deeds made by the solicitor," and that there is no "difference between this case and the case of an artist who is employed to paint a picture or design a coat of arms, where the property passes to the employer." It would have seemed to us that the legal documents and the paintings were objective things *per se*, whereas the architectural drawings were not objective, but merely means to an end. It is not for us, however, to lay down the law, and the fact remains that, in the absence of express provision to the contrary, the drawings become the property of the building owner. The architect who has any particular reason or fancy for retaining his drawings can attain that object by express stipulation agreed to before he undertakes the work.

A Factor in the Shop-front Problem.

AT a time when considerable attention, both professional and public, is being given to the shop-front problem, it is well to point out a certain aspect of it which is in danger of being overlooked. On one side we have the advocates of the purely architectural effect of shop-front design and on the other the shopkeepers, who appear to be moved by business motives only. The point to which we would draw attention is that shopkeepers occupying premises in an important thoroughfare like Regent Street should recognise (or should be made to recognise) that they have a civic duty to perform in addition to acts of business; in other words, Regent Street being a civic asset, they should be compelled to build their new shop-fronts in such a way that the architectural effect of the thoroughfare is not destroyed. And if they insist on plate-glass down to within an inch of the pavement and the whole shop-front being enclosed by narrow beads that fail to give the necessary effect of support, then every hope of a successful result will be destroyed. Of course, we know the shopkeepers will say at once that all this is very excellent, no doubt, but that, as a fact, they find themselves in the midst of a keen competition, and that they cannot afford to sacrifice an inch of space just on account of æsthetics. But we have yet to be convinced that this demand for every inch being absorbed in the plate-glass area really has any good reason to warrant it. The problem is obviously a very difficult one, but it will only be settled on the lines of fair architectural effect in conjunction with a recognition of business needs. To attempt a solution the other way round is to court failure.

THE LATE MR. D. H. BURNHAM.

MR. DANIEL HUDSON BURNHAM, the eminent American architect, whose death was announced on June 2nd, had been long in the forefront of his profession in the United States. In that country there would be no need to apologise for his numerous giant structures, where the Flat-iron Building in New York; the First National Bank, Chicago; the People's Gas Company Building, Chicago, and the Commercial Bank Building in the same city, and his other successful solutions of the height problem, do but enhance a reputation that, for British and Continental architects, rests more securely on his splendid essays in town planning, and on his dominating influence over "one of the greatest architectural achievements of modern times"—greater, probably in its consequences than in its actual achievements—the Columbian Exposition of 1893, which was better known as the "Chicago World's Fair," and had an enormous influence on subsequent architecture in the United States.

Daniel Hudson Burnham was born at Henderson, Jefferson County, New York, on September 4th, 1846. He was therefore, at his death, in his sixty-sixth year. He began to study architecture in Massachusetts in 1864, and, returning to Chicago in 1867, he entered the office of Messrs. Loring and Jenney. After the great fire his share of the rapid rebuilding of the city was performed in association with the firm of Messrs. Coster, Drake, and Wright, by whom, in 1871, he was engaged as assistant. The firm of Burnham and Root was established in 1873, when Mr. Burnham entered into partnership with Mr. John Wellborn Root. This firm soon became distinguished by a greater regard for fine results than was then common, and, in particular, their Monadnock building, though a plain commercial structure, absolutely destitute of mere ornament, won the admiration of public and profession alike by its good proportions and excellent lines, and was perhaps the first positive evidence of Classic taste in the design of office buildings in America.

In September, 1890, Messrs. Burnham and Root were appointed constructing architects of the Columbian Exposition, and a month later Mr. Burnham was made Chief of Construction. In the following January Mr. Root died, and Mr. Burnham was appointed Director of Works. In that capacity he arranged for the control of the scheme by a Board of Architects, and for the assignment of the different buildings to different architects. The Board included men whose names thenceforward were to stand pre-eminent in American architecture—Richard Morris Hunt, Charles Follen McKim with his partners Mead and White, Peabody and Sterns, Denkmarr Adler, Louis Sullivan, George B. Post, Henry van Brunt, W. L. B. Jenney, and Charles Bowler Atwood, who became chief assistant to Mr. Burnham, who afterwards took him into partnership; while Mr. Ernest Graham was made Assistant Director of Works, and was also taken into partnership. Mr. Burnham obviously had a keen eye for character and ability, and he has been described by a United States Senator as "a great artist, a great engineer, a great organiser, and a great diplomat." This extraordinary combination of qualities having been fully manifested in the striking success, architecturally, of the Columbian Exposition, the importance of Mr. Burnham's labours was recognised in a great banquet, which was given in his honour in New York; in the conferring upon him of the honorary degree of Ph.D. by Harvard University; and in his election, in the following year, as president of the American Institute of Architects, to which position he was re-elected in 1895. At the end of this second term he was elected a director of the Institute for three years.

Mr. Burnham's energies were thereafter largely absorbed in the design of commercial buildings, of which a long list was given, with illustrations of several of them, in our issue of October 6th, 1909. His feeling for architecture, however, was more congenially expressed in his

fine design for the Field Columbian Museum at Chicago, which ranks among the very best of American architectural productions. An equally meritorious work is the Union Station at Washington, D.C., illustrated in our issue for March 20th last.

In 1901 the United States Senate ordered plans for the development and improvement of the entire park system of the District of Columbia, when, on the advice of the American Institute of Architects, Mr. Burnham and Mr. F. L. Olmstead, jun., were appointed expert advisers (with power to add to their number) to the committee entrusted with the scheme, and subsequently Mr. C. F. McKim and Mr. Augustus St. Gaudens were co-opted. The splendid work Mr. Burnham did on this committee of experts, of which he was chairman, is now a matter of history, and has been already recorded in the pages of this journal (October 6th, 1909); so also were his re-planning of Manila and of Baguio in the Philippine Islands; his brilliant monumental study (1904) for the re-planning of San Francisco, in which he was assisted by Mr. Edward H. Bennett; and his great scheme for the lay-out of Chicago, a gigantic work for which, while it doubtless embodied the ideas of many minds, he was chiefly responsible. This last great conception—embodied in a volume of drawings published in 1909—would alone secure his reputation as an imaginative as well as a constructive architect of the highest eminence.

As a man, Daniel Hudson Burnham was esteemed for his self-sacrificing public spirit—his services in the great schemes upon which his assistance was sought were often purely honorary—for his invariably generous recognition of the help he received from other hands, even when such assistance was purely subordinate, and for his "cold head and warm heart, which never mixed, but were always in touch with each other." One who worked with him on the Columbian Exposition has said: "In meeting him I always felt a thin sheet of ice was between us, but a generous man on the other side." It was this cold-drawn intellectuality, beneath which there was so obviously a just mind and a generous heart, that made him a trusted leader of men, and energised and made prolific the remarkable talent that placed him at the head of his profession in America.

THE LATE MR. D. H. BURNHAM.

Mr. Burnham's scheme included an immense drill ground situated at the foot of Telegraph Hill on the north-east side of San Francisco. It was proposed to leave the hill intact as to mass, but to crown it with a park and a monument symbolical of some phase of the city's growth. Magnificent terraces around the heights, such as shown in the foreground of the above illustration, were prominent features of the scheme.

THE LATE MR. D. H. BURNHAM'S SCHEME FOR THE LAY-OUT OF SAN FRANCISCO: THE DRILL GROUND.

The above illustration shows the vast amphitheatre, situated in a natural hollow 800 ft. above sea-level, which formed part of Mr. Burnham's scheme. This amphitheatre was to be used for inter-collegiate football games, Olympic contests, horse shows, and polo matches. Mr. Burnham would appear to have been inspired by the Stadium in the Delphian hills, overlooking the Gulf of Corinth, or the Theatre of Dionysius, at the foot of the Acropolis, Athens.

THE LATE MR. D. H. BURNHAM'S SCHEME FOR THE LAY-OUT OF SAN FRANCISCO : THE AMPHITHEATRE.

PARIS SHOP-FRONTS, OLD AND NEW.

THE treatment of shop-fronts is a matter about which more or less heated controversy seems to be perpetual, the purely architectural view of the subject being always more or less sharply divided from that of the shop-keeper. This unfortunate divergency has recently become acute, even to the intrusion of personalities which, to say the least of them, are untoward as merely complicating a problem that clamours for solution through some sort of mutual agreement. "Temper," in this instance as in so many others, "defies the matter" as effectually as did the Shakespearean clown's "tricksy word," and should therefore be rigorously ruled out as being foreign to the issue.

"Foreign to the issue" in another and not an adversative sense is the practice abroad with regard to shop-front design. What is being done by our French neighbours, for example, should, and undoubtedly does, prove really helpful towards a rational solution of the problem in our own towns. London, especially, has already profited greatly by French example in this as in other architectural matters; and the accompanying illustrations

OLD PHARMACY, RUE DE GRAMMONT.

AN OLD BUTCHER'S SHOP, RUE DE VARENNES.

of some old and new shop-fronts in Paris will no doubt be welcomed as a substantial contribution towards the solution of a vexed question that seems ripe for settlement.

Shops in some form are coeval with commerce or sale and barter. The man who had goods for sale would at once require some sort of stall or stance on which to display them. Afterwards he would require some means of protecting them from the weather. On these simple lines the shop must have been developed. At first it must have been easily portable, as it is to this day in fairs and periodical markets. The "establishment"—does not the very name seem to suggest an advance on itinerant trading?—was obviously a later growth of civilisation.

Numerous examples of shops are found in Pompeii. The counters, generally of stone, project into the public way, and the open-air shop was closed when necessary by means of boards sliding in grooves.

Glazed fronts are, of course, of comparatively recent origin. Up to the end of the fourteenth century, the shop-front consisted of a couple of shutters closing on each other horizontally. The upper shutter, hooked to the lintel, could be swung out to form a sort of pent-roof to shelter the goods that were displayed on the lower portion, which was propped up horizontally from the ground to form a kind of counter, the shop being closed by drawing the one leaf down and the other up so that the pair met, and security being obtained by means of

iron bars, so that "shutting shop" was a very simple operation.

A long period elapsed before shops proper—that is to say, those so constructed that customers could get inside them—were evolved. Shops of this kind were hardly available before the period of the Renaissance and it was a long time before they began to acquire any distinctive character relative to the uses to which they were put. A common design, and characterless attempts at decoration, served for all trades.

Even at the present day the architect, to whom shop-front design is, in Paris as elsewhere, too rarely confided, finds himself at a considerable disadvantage owing to the fact that the particular business of the shop was not predetermined when the building to which it is attached was erected. The skeleton which is left for him to clothe—the stone pillars or iron columns to which he must accommodate his design—are at once prescriptive and prohibitive and must often sadly hamper his attempts to produce appropriate design and decoration. He has to make the best of things as he finds them. If, as sometimes happens, he is a man of strong individual

OLD PHARMACY, RUE DU FAUBOURG, ST. HONORÉ.

SHIPPING OFFICES, RUE SCRIBE, PARIS. CH. BREFFENDILLE, ARCHITECT.

temperament, he may nevertheless succeed in producing a design which, while extremely interesting in itself, is in dire conflict with the building which it fronts and with all the other shops in the street!

The street by-laws for Paris which came into force in 1902 give great freedom with regard to projections. Varying according to the street widths, the general projection of the base of a shop-front on to the public way may be from twenty to thirty centimètres. The cornice above the window may jut out to fifty to eighty centimètres, signs to two mètres, and canopies three mètres.

With regard to signs and canopies, a French writer complains that in spite of an æsthetic demand for the more general adoption of the beautiful wrought-iron work of which former centuries have left us so many excellent examples, there seems but little disposition in modern Paris to follow such models in framing signs or supporting canopies. Yet they would add much variety and charm. The same writer, in supporting his advocacy of ironwork, makes a point that may be commended to the thoughtful attention of the uncompromising all-glass advocates. The object to be attained in shop-front design, he reminds us, is not only to attract the customer, but to impress his or her memory with some striking characteristic that will effectually prevent its being confounded in the recollection with any other establishment. The lust for the last possible particle of window space is also implicitly condemned in the observation that the number of objects exhibited should be restricted, and if they are so cunningly disposed as to set each other off—to be complementary the one to the other—the effect will be much more pleasing and attractive than a lavish profusion that would prove distracting.

The objects displayed should receive help not only from each other, but from the design and decoration of the shop-front, which should conform harmoniously in form, material, and colouring to the class of goods exhibited in the shop.

The materials of which the front is constructed should not have their natural aspect in any way disguised. For example, wood should not be tortured into fantastic curves. The front should, upon occasion, be so recessed as to allow the prospective customer to inspect the windows with comfort—that is, without being jostled by passers-by, and, incidentally, without hindering the pedestrian.

Where the frontage is sufficiently wide, it may be conveniently divided into two equal parts by the entrance, which should be set back sufficiently to afford side views on left and right of the contents of the windows. When it is possible, as in the front of the Compagnie Générale Transatlantique, in the Rue Auber, to divide the front into two portions horizontally, an effect of amplitude is obtained, as well as facilities for decorative treatment by

means of sculpture or otherwise. It is rather surprising to find that Paris offers so few examples of this arrangement.

Inscriptions of all kinds may be made to contribute effectually to the decorative effect of a shop-front, or, by their badness, they may have the opposite influence. They should be used sparingly, should express character, be judiciously disposed, proportioned in size to the importance of the idea which they are intended to convey, and be composed of letters which are in themselves decorative. In Paris, as with us, this ideal is far too seldom realised: much of the lettering being in disgracefully bad taste. Illuminated signs, some of them quite tasteful, are being increasingly used by the Paris shop-keepers; the illuminant being, of course, electricity.

As examples of dignified old shop-fronts in Paris we illustrate two old pharmacies, one of which—that in the Rue du Faubourg St. Honoré—is now, as will be seen,

SHIPPING OFFICES, RUE SCRIBE: MAIN ENTRANCE.

BOOT SHOP, BOULEVARD DE LA MADELEINE.

occupied by a dealer in antiquities, while the other, in the Rue de Grammont, is still devoted to drugs, preserving, we are told, not merely its original outward appearance, but the very utensils and fittings. Both shops date from the period of the First Empire, and possibly the authorship of each is identical.

It is perhaps of doubtful propriety to describe the fine front of the Compagnie Générale Transatlantique, in the Rue Auber, as a shop, but the crudeness of the classification will be condoned in contemplation of the dignity of M. Nénot's monumental design. The framework is of bronze, the two figures symbolising respectively Commerce and the French Marine, the decorations comprising marine vegetation. Marine decorations also adorn the two fine flanking doorways. The dolphins above them are in bronze.

The American shipping offices in the Rue Scribe were designed by M. Ch. Breffendille, who has made very effective use of his Order in pilasters, and of various

kinds of marble, the metal-work being relieved with a certain amount of gilding. The front entrance door is of oak varnished, with bevelled glazing.

The dyer's shop in the Boulevard de Courcelles has its front constructed in green marble, with restrained decorative features in bronze. The design, of which the architect was M. J. Marrast, is chiefly characterised by a dignified simplicity of line, but the general effect rather tends to heaviness, the pilasters and the fascia being on too large a scale.

The very modern-looking two-stage shop-front of the refreshment-house in the Rue de Sèvres shows a sufficient expanse of glass. The bronze ornamental detail is partly gilded. The luminous sign, for example, is decorated with gilded garlands. Whether the first word on this sign is intended for the French word for tea, or for the English definite article or definitive adjective is an *équivoque* that may possibly be intentional, seeing the weird essay towards "the English" which in the windows

GRANDS MAGASINS DU PRINTEMPS.

SOME PLANS OF PARIS SHOP FRONTS.

TEA SHOP, RUE DE SÈVRES, PARIS.

quaintly announces "The Lunch"—a form of words that is delicately fragrant of "English as she is wrote."

It is not, of course, here contended that in the matter of shop-fronts Paris leads London. On the whole, we feel strongly disposed to say that the converse is the case, and that London would come out quite triumphant on a fair comparison. In fact, some of the most successful shop-fronts in Paris have been designed and constructed by London firms—a consummation that speaks for itself. It may be noted, however, that apparently the Paris shopkeeper does not clamour for the supply of every inch of glass that the space will hold. He feels that by thus defying the canons of architecture he would offend the artistic taste inherent in the French people, and would thus achieve the opposite effect to that intended, the seeming gain becoming actual loss in the ultimate issue. He knows that more space for the display of wares is of much less account than their artistic disposition, and that the distinction and character at which he aims is largely dependent on architectural effect; whereas the all-glass window, lending itself to lavish profusion of display, is of doubtful commercial wisdom.

HOUSING QUESTIONS IN THE
COMMONS.

In the House of Commons last Wednesday, Mr. W. Guinness asked why so little action had been taken under Part I. of the Housing and Town Planning Act, 1909. There was said to be reluctance on the part of authorities to undertake the risk of housing schemes, but why had nothing been done to carry out what was said to be the main and essential feature of the proposals of three years ago? In rural areas there was great shortage of housing accommodation; the effect of past and fear of future legislation had brought about stagnation in building, and owners were not disposed to sink money in working-class dwellings.

Mr. Bentham, member for Gainsborough, said he represented a large agricultural constituency with nearly 100 villages, but in not one of those villages was the housing accommodation adequate, and in many of them the cottages were a perfect disgrace to civilisation.

Lord H. Cavendish-Bentinck agreed that in many parts of the country the Housing Act was a dead letter. In the report for the county of Norfolk the medical officer stated that many of the houses were unfit for habitation and ought to be demolished; but if the tenants were turned out there was nowhere else for them to go. There was not a village in which houses were not wanted. During twenty years the Local Government Board, with all its

experts, had got only 200 cottages built, whereas the Board of Agriculture in three years had procured the erection of 1,000.

In reply, Mr. John Burns said he was so anxious to improve the housing in Norfolk that five weeks ago he gave an inspector instructions to go into that county, see what the local authorities were doing, and enforce upon them the necessity of exercising their powers. Three rural district councils had since applied for loans for housing, and several urban district councils in Norfolk had made similar applications. At Chertsey cottages were now in process of erection on an appropriate site. The local authorities, under the pressure of the Board, were increasingly responding to the call for housing and town planning, and doing their work. Considering the short time the Housing and Town Planning Act had been in operation, and the slowness with which some local authorities, including even the London County Council, moved, he thought that, on the whole, reasonable progress had been made. It had been suggested that three Housing Commissioners should be appointed. Mr. Burns could not accept that suggestion, but he might appoint four or five housing inspectors, who would do more good in one year than the housing commissioners would do in five or six. To take as the measure of housing reform what local authorities themselves did was entirely to ignore what private enterprise was doing, which was seventy or eighty times more than what local authorities attempted.

NEWS ITEMS.

The Architect for St. Paul's Bridge.

Sir Ernest George having been appointed architect for the rebuilding of Southwark Bridge, it is now announced that Sir William Emerson, F.R.I.B.A., will act in a similar capacity in respect to the new St. Paul's Bridge, the engineer for both structures being Mr. Basil Mott. Sir William Emerson, who has been president of the Royal Institute of British Architects, passed the earlier part of his professional career in India, where he designed Lucknow Cathedral, the Bhonnuggur Hospital, the buildings for Allahabad University, the Victoria Memorial at Calcutta, a palace for the Maharajah of Bhonnuggur, the Bombay Markets, and several churches. Among his works in this country are Hamilton House on the Victoria Embankment, the Royal Caledonian Asylum, and St. Mary's Church, Brighton. He was one of the three architects appointed to represent architectural opinion before the Committee of the House of Commons when the Bridge Bill was before Parliament.

A Summer School of Town Planning.

The Association of Garden Cities, in furtherance of Mr. Burns's suggestion, has now decided to hold an experimental summer school of town planning—on University Extension lines—at the Hampstead Garden Suburb during the first fortnight of August. Short courses of lectures will be given, and also practical demonstrations of how town planning should be carried out.

Presentations to Mr. A. Y. Nutt.

Mr. A. Y. Nutt, M.V.O., I.S.O., who has just retired after forty-four years' service at Windsor Castle, has been presented by the staff of his Majesty's Office of Works, the Lord Chamberlain's Department, contractors, workmen, and friends at the Castle, with a silver-mounted dressing-case. Mr. Nutt also received a gift from the Windsor Castle police, in the form of a silver cigarette case.

New Hospital at Hounslow.

On June 1st Lady Jersey laid the foundation-stone of the new hospital at Hounslow, which is being built, as a memorial to King Edward, on a site fronting the main road to Staines. Mr. J. E. Franck, F.R.I.B.A., is the architect.

Bow Church Safe.

Mr. Underwood, F.R.I.B.A., who was consulted on the condition of the tower of the Church of St. Mary-le-Bow, Cheap-side, reports that, in spite of slight decay, the stability of the fabric is not impaired. Certain repairs are to be carried out at a cost of £360.

Forthcoming Archaeological Congress.

The twenty-third annual Congress of Archaeological Societies in union with the Society of Antiquaries of London will be held at Burlington House on Thursday, June 27th, at 10.30 a.m., when Dr. C. H. Read, President of the Society of Antiquaries, will take the chair.

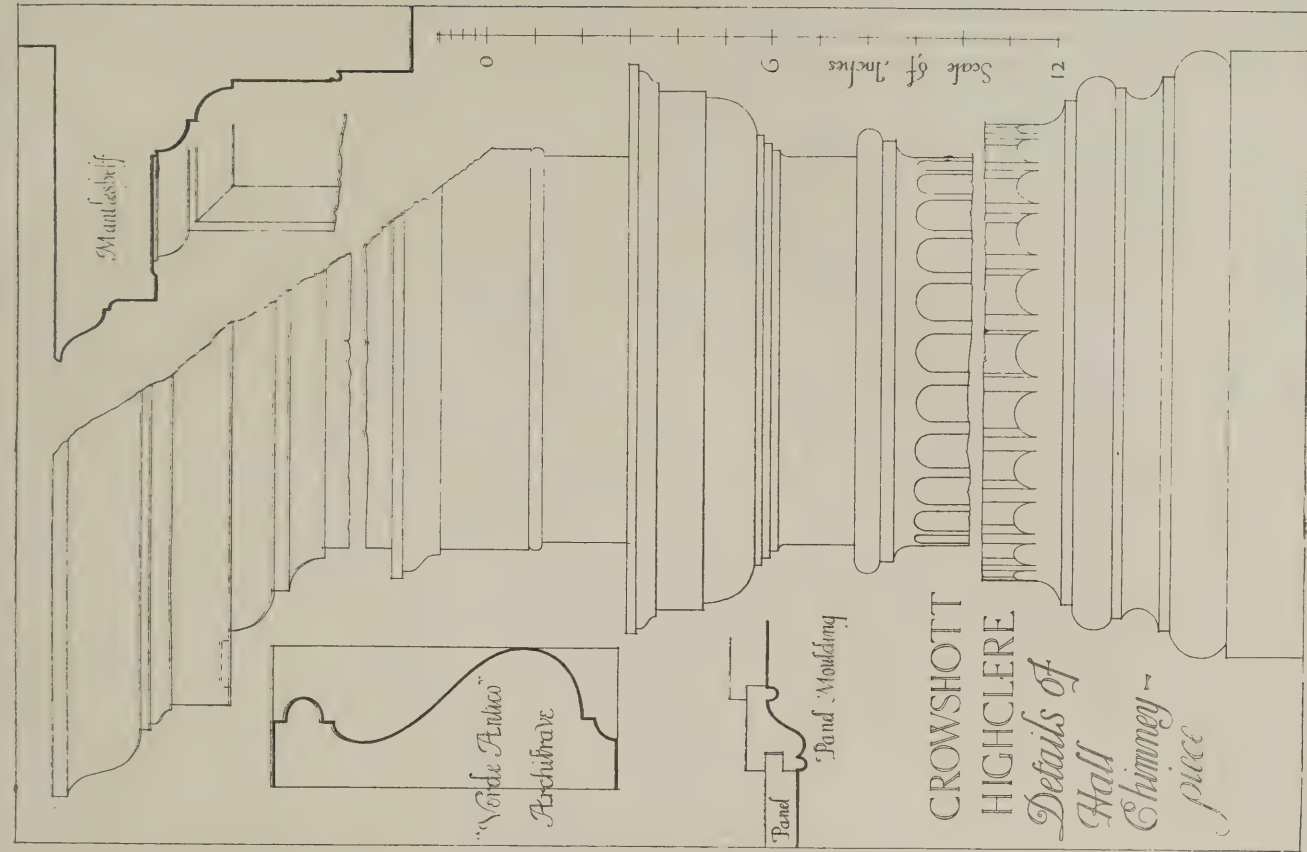

DETAILS OLD AND NEW.—XLIII.

A Modern Chimneypiece.

The hall chimneypiece at "Crowshott," Highclere, designed by Mr. Francis Bacon, is an excellent example of modern work. It is of deal painted white, with a surround of verte antique marble. The design is quite simple, there being an entire absence of applied ornament.

THE NEWER RESPONSIBILITIES OF ARCHITECTS.*

BY WILLIAM WOODWARD, F.R.I.B.A.

The author has evidently made a very close and careful study of the important case of Minter v. Waldstein, and from the judgment of Mr. M. Muir Mackenzie, the Official Referee before whom the action was brought, he deduced some useful conclusions.

THE position of client, architect, and builder to-day is altogether different from that existing say forty or fifty years ago. An architect was not then subject to anything like the interference in the performance of his duties which, unfortunately, now too frequently prevails.

Responsibility in building operations is increased, too, very largely by reason of the "rush" attending work, which used to take its leisurely and safe course with corresponding satisfaction to all concerned. The more serious results of this regrettable modern necessity are that architect and builder are made responsible for defects which would not arise if a proper amount of time were allowed, first, for the studious preparation of the drawings and specifications, and, secondly, for an adequate time to build properly, allowing sufficient time between the trades for the work to approach some sort of dryness. When trouble does arise, it is difficult to make judges understand that very many tons of water are still in the walls and fire-resisting floors; that such water must get out somehow or other, and that it is not fair treatment to be compelled to go on with the plastering with walls and floors reeking with moisture, and, worse still, to have to fix well-seasoned joiners' work to wet plaster. It is difficult, too, to make judges understand that the better seasoned the wood is the worse is the effect of moisture upon it.

The trial, "*Minter v. Waldstein*," lasted for thirty-nine consecutive days, commencing on July 5th and terminating on August 18th, 1911, judgment being given on October 20th, 1911. The contract—which was in the form known as "The Institute Form"—was to make certain alterations and additions to a large country mansion in Cambridgeshire, named "New-on Hall." The total cost of the works, including many additions to the works included in the contract, amounted to the sum of about £21,000. The work was commenced in February, 1910, and completed in September, 1910, the defendant moving into the house a few days after September 22nd. Certificates, as usual, were given by the architect during the progress of the works, and on January 20th, 1911, he issued a certificate for £2,750. On February 7th, 1911, he gave a final certificate for £533, stating that the latter sum was the balance of the money due to the plaintiff with the exception of £500, being the retention money under the contract to provide for the making good of defects which might appear during the period of six months after the completion of the works. The defendant, besides denying that he was liable to pay the sums last certified, pleaded a counterclaim for damages and recovery of certain sums which he asserted were improperly included in progress certificates. Some 400 items were set forth by the defendant as those to which he objected; and the bill of variations on the contract prepared by the Quantity Surveyor occupied 327 pages.

Having outlined the history of the case

down to the trial by Mr. M. Muir Mackenzie, Mr. Woodward went on to deduce some important points as affecting client, architect, and builder, which he conceived to be involved. The defendant alleged that letters of January 10th operated to determine the architect's employment and his authority to give a certificate after that date. Mr. Muir Mackenzie raises the question whether an architect can be effectively discharged from his office by the employer alone; and he quotes cases bearing on the point. It seems that the architect, being the one agreed upon between the parties, cannot be discharged by the employer alone. The defendant placed reliance on Clause 3 of the Articles of Agreement, which provides for the nomination by the employer, subject to objection by the contractor, of a fresh architect in the event of the death of the one named in the contract, or his ceasing to be the architect for the purposes of the contract, but Mr. Muir Mackenzie decided that that clause did not operate. Mr. Woodward gathers also that an architect's certificate might not be justifiably held to include for work outside the work contemplated in the contract, and that "in regard to all extra work ordered, either under the contract or in circumstances which created in the defendant a liability to pay for it, the provisions of the contract as to payment were to be observed—i.e., that on the one side defendant was not until the completion of the whole works liable to pay except on the interim certificates of the architect, and then only for the amount certified, and that, on the other side, the certificates were to include the price of all the work ordered as above mentioned." Mr. Woodward therefore presumes that in this particular case the architect was justified in issuing certificates for work which, although not specifically included in the contract, were executed with the cognisance of the employer, and were therefore subject to all the conditions of the contract.

Mr. Muir Mackenzie decides that, where the particular surveyor named in the contract has measured and valued additions for which the defendant was liable under the contract, or an omission properly authorised, then such measurement and valuation are decisive. As it is not infrequently the case that builders employ a surveyor to measure and value for them the variations on the contract, it is well to bear in mind that the ultimate decision on these matters rests with the surveyor named in the contract.

As to the responsibility of the architect for the quality of the timber and general construction of the roofs and floors. In Mr. Muir Mackenzie's opinion the authorities show that, in a contract like this, the power of the architect to order or sanction variations does not empower him to authorise departures from the terms of the contract which involved the substitution, in the whole or part of the work, of "inferior" materials and workmanship for those prescribed and charged for in the contract price so as to prejudice the strength and stability of the building.

Mr. Muir Mackenzie states his opinion that as regards the "quality" of the wood,

the onus of proving that it was inferior and unseasoned was on the defendant, and that he has not discharged it.

A matter of some importance was that the defendant claimed, in his damages, the cost, or some of the cost, of removing, storing, and bringing back his furniture during the works of repair of defects; and further the cost of employing professional assistance in the work of reconstruction or repair; but, on the authority of "*Green v. Eales*," Mr. Muir Mackenzie disallowed these claims.

Another matter of some importance raised in this case was with reference to what were, and what were not, authorised extras. The defendant's contention was in effect that no extra work could be charged for unless authorised by writing or drawings signed by the architect, or by a written approval after having been done. The plaintiff contended, in opposition to this, that he (the plaintiff) was entitled to be paid for all additional or extra work or materials which had in fact been ordered or sanctioned by the architect or by the clerk of works, or by the architect's deputy or assistant, or by the defendant or his wife, or had been rendered necessary in consequence of variations so ordered or sanctioned. Clauses 12 and 13 of the conditions of contract deal with this matter. On the construction of these clauses Mr. Muir Mackenzie found in favour of the defendant. The summing up of Mr. Justice Day in "*London School Board v. Wall*" is cited, in addition to other cases, in support of this view. The question as to how far the defendant could be held liable for extras of which, perhaps, he had no cognisance is dealt with as follows by Mr. Muir Mackenzie. He says: "On the one hand, where an employer has protected himself by a written contract for a lump sum, the mere fact that he sees, sanctions, or permits, or discusses variations in the carrying out of the contract, does not impose on him a liability to pay any extra cost, unless he is plainly told, or must know from the circumstances, that the variations will mean an extra charge to him. Being, of course, ignorant of the details of the contract work, he is entitled to the protection of his contract." The cases quoted in favour of this view are "*Lovelock v. King*" and "*Thausis Company v. McElroy*." But, on the other hand, it is equally the law that if an employer desires the builder to make alterations, and additions, and omissions, and sees extra expenditure being incurred upon him of which he takes the benefit, he cannot refuse to pay on the ground that the expenditure was incurred without proper orders given for the purpose. The case quoted in favour of this view is "*Hill v. South Staffordshire Railway Company*."

The question of discount from payment to sub-contractors also arose in this case. It appears that the condition in the bill of quantities is quite clear on the subject of provisional items supplied by firms, viz., "That the contractors must pay the amounts in full and produce the receipts before the amounts can be included in the certificates on which the defendant is liable." The defendant claimed to have a deduction of 5 per cent. from the account of one of the sub-contractors on the ground that if it had been paid promptly there would have been a discount of 5 per cent. of which the defendant would have been entitled to the benefit. Mr. Muir Mackenzie disallowed this objection, and added that he thought Section 28 of the conditions of contract equally clear, and

* Extracts from a paper read before the Royal Institute of British Architects, June 3rd.

that only amounts which had been paid to firms and tradesmen could be included in the certificates. This Clause 28 differs from the above quoted condition in the bill of quantities, which provides for the production of the receipts of the sub-contractor by the contractor before the amount is included in the certificate. Clause 28 does not require the production of such receipt before a certificate is granted in which the amount is to be included, and this fact has caused in other cases much discussion between architects and builders.

The author could not help expressing regret that the plaintiff was not allowed to do what he was perfectly willing to do, and in fact was bound to do under Clause 17 of the contract, and that was to go down and make good all defects which had appeared in the house before the first architect was superseded by another.

As regards the responsibility for making good defects arising from faulty construction, Mr. Muir Mackenzie has not laid down any clear and decided opinion, but he rather judges each item on its merits. The author had hitherto thought that, as regards defective materials and workmanship, the builder was responsible, but as regards the mere carrying out of the designs and directions of the architect, the architect or the client was responsible for bad results. H.M. Office of Works deals with this particular matter in a manner which, to the author's mind, was quite fair. There is a clause in their contracts which runs as follows: "But if any failure shall have arisen in the work, or any part thereof, by reason of a defect in the design of the architect, then the builder shall not be responsible for such failure, and the same shall be made good as extra work under Article 7 of these conditions if so required by the Commissioners."

There can be little doubt that the many actions which have been fought during the last few years have brought to the front responsibilities and troubles never before realised by architects and builders. Our present conditions of contract do not provide in any way clearly for the settlement of these troubles, and it becomes day by day more urgent that these conditions of contract shall be revised, for the protection alike of client, architect, and builder.

HOUSE AT GERRARD'S CROSS.

This house has been erected at a cost of £820, inclusive. The desire of the client was to get as much accommodation as possible for the sum to be expended, and therefore there was no money to be spent on effect. The simple Georgian treatment tended to reduce the cost, and also seemed suited to the locality. Local bricks and tiles were used, and a little relief was gained by using tile quoins. The architects were Messrs. Acworth and Sheppard,

of 5, York Buildings, Adelphi, W.C., and the builders were Messrs. J. C. Richards and Co., of Kilburn.

IN PARLIAMENT.

(By Our Press Gallery Representative.)

Memorials in the Parks.

During the discussion on the Vote for Royal Parks and Pleasure Gardens in Committee of Supply of the House of Commons last week, Lord A. Thynne took exception to the character of the memorials that were put in some of the parks. For instance, he said, they had the Duke of York Steps. There they had a very handsome memorial obviously designed to be put in the middle of a straight line, but it had been put at the corner of a fence. In a case of that sort the Office of Works had not bestowed two minutes' consideration to the choice of a site suitable to the character of the memorial, or to the choice of a design suitable to the particular site. In the first place they wanted in the Office of Works an expert in landscape gardening and in the second place an expert in forestry. The reason why the Royal Parks could not be compared favourably with the parks maintained by the London County Council was largely the absence of expert advice in landscape gardening and forestry.

Mr. Whitehouse pressed for information as to what view the Government took of the feeling of the House regarding the King Edward Memorial. He hoped the design had been referred back. He repeated his protest against erecting statuary in public parks.

Captain Jessel suggested that the time had come for replacing the present light standards in the Mall by more ornamental standards.

Mr. Noel Buxton criticised the King Edward Memorial site in Green Park, and maintained that the memorial should not be such that the Green Park would be a setting for a single monument as St. James's Park was already a setting for the Queen Victoria Memorial. The improvement of Hyde Park Corner would, in his opinion, prove a better memorial than the one proposed.

Mr. Burdett-Coutts also spoke against the selected site for the King Edward Memorial and the subordination of the actual statue of King Edward in the design.

Several other members raised questions regarding the administration of the Royal Parks and Gardens.

Mr. Wedgwood Benn, replying on behalf of the First Commissioner of Works, said that it was proposed to replace the lamps in the Mall with others of a more worthy design. He assured Lord A. Thynne, and other members who criticised the technical ability of the Department's officers in re-

gard to landscape gardening, that they were under a misapprehension. The superintendent (Mr. Gardner) was a man of very great experience in landscape gardening and forestry and advice was given by a well-known expert in forestry. With regard to the King Edward Memorial he did not wish to repeat his previous statement on the subject. The point narrowed itself down to this. The only decision which the First Commissioner had to make was whether or not the Green Park site was a proper site. The matter of design and the matter of the disposition of the money were matters which could have been raised before the Memorial Committee. The present scheme enabled a large space of over eight acres to be opened in Shadwell.

Rodin's "Burghers of Calais."

On the vote for the Houses of Parliament Buildings, Mr. Whitehouse declared that the new Victoria Embankment Garden was not a suitable place for the erection of Rodin's group—the "Burghers of Calais." The statuary required an historic and especially an architectural setting. He suggested that the Office of Works should remove at an early date the varnish from the very beautiful oak-work which adorned the Houses of Parliament.

The Maclise Frescoes.

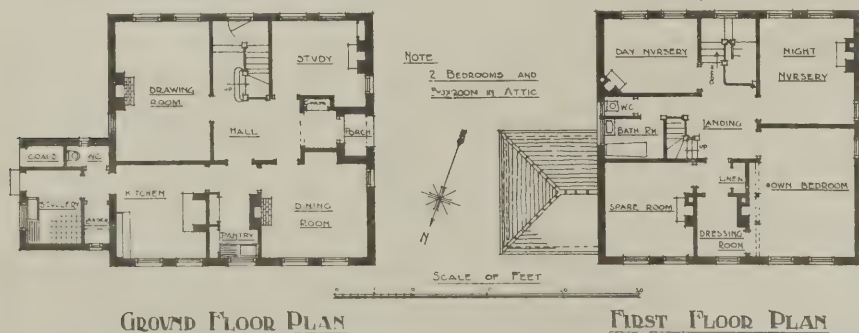

Mr. John O'Connor asked what steps were being taken to preserve from decay the Maclise frescoes in the Royal Gallery representing the death of Nelson and the meeting of Wellington and Blücher on the field of Waterloo.

The Ladies' Gallery Grille.

Mr. Alexander Whyte suggested that the grille in front of the Ladies' Gallery should be removed.

Sir J. D. Rees introduced the subject of the lighting of the Chamber, and wished an assurance that the opinion of the House would be taken before electric lighting was substituted for gas lighting.

Mr. Wedgwood Benn, in reply, said the facts with regard to the Rodin group of statuary were these. A copy of the original statue stood in a square in Calais itself, and a copy was very generously given to the First Commissioner by the National Art Collection Fund. It awaited some place on which to stand and it was proposed to put it in some suitable place in the Victoria Tower Gardens. He did not know that he could give any particular historical reason why it should be placed there except that Queen Philippa had some association with the Abbey of Westminster, where she was crowned and buried. The matter could not be completed for some time, nor until the County Council had carried out its projected improvements. It would be well into next year before any definite steps could be taken. With regard to the Maclise frescoes in the Royal Gallery, the Office of Works had the constant advantage of the advice of Sir Arthur Church, and the Committee might rest assured that such steps were taken as were necessary to safeguard and restore those works of art. As to the removal of the grille from the Ladies' Gallery, he did not think any person, with one or two exceptions, had expressed a view favourable to the removal of the grille. He could not undertake to carry out the suggestion unless it could be shown that there was a majority of opinion among honourable members in favour of the removal and also a similar balance of opinion among the ladies who occupied the gallery. As to the lighting of the Chamber, it was necessary that there should be a change. At present the House was lighted by

HOUSE AT GERRARD'S CROSS, BUCKS. ACWORTH AND SHEPPARD, ARCHITECTS.

North Front, to Road.

groups of circular Argand burners of a very old-fashioned type, and in order to maintain the proper amount of illumination on the floor of the House some alteration was necessary. The substitution of clusters of electric lamps would produce exactly the same effect, as regards the strength and tone of the light, as that produced by gas, with other advantages in the way of economy and improvement of the ventilation. The saving would be £140 yearly. They would be able to revolve the plant which ventilated the House at a greater speed, and they would get a better flow of air through the Chamber. At present, if they turned the apparatus beyond a certain speed there was a danger of blowing the lights out.

In Defence of Gaslight.

Lord Balcarras regretted the proposal to change the lighting. He could not find out after all his inquiries in the House of Commons that gas had a fatiguing effect as an illuminant or that there was a demand for this alteration. The lighting and ventilation were infinitely superior to anything that could be found in any other chamber or place of assembly where any

South Front, to Garden.

Garden Terrace.

HOUSE AT GERRARD'S CROSS, BUCKS ACWORTH AND SHEPPARD,
ARCHITECTS.

service or performance went on uninterruptedly hour after hour.

The Neo-Classic "Rage."

Mr. Noel Buxton, who urged that the removal of the varnish from the oak carving should be proceeded with at once, said that in time to come, when the rage for neo-Classic building had had its day, there would be a reversion to Gothic, and that House would come to be regarded in a hundred years as by far the greatest memorial of the Victorian Age. It was, therefore, unworthy that such a trivial sum required to make it as beautiful as it should be in regard to good carving should not be readily expended.

Ventilation.

Mr. C. Bathurst, referring to the ventilation of the Chamber, said that during the Autumn Session he found his body in a fairly hot climate and his legs suffering from the blast of an east wind.

Mr. Wedgwood Benn said that if he was informed of variations in the temperature he would have investigations made. With

regard to the lighting he hoped members would not come to a final opinion before seeing the temporary and experimental alteration.

Designs for Public Buildings.

On the vote for Public Buildings, Mr. Whitehouse directed attention to the practice of allowing the designs for the great Departmental buildings to be settled within the Office of Works, a practice which prevented the architects of the country generally from entering a competition for the designing of Government buildings. The designs, he thought, ought to be open to national and if necessary international competition.

Lord A. Thynne recommended the Government to adopt the policy of selecting a wider range within which to build public offices. Economy would result if they refrained from concentrating Government offices in Whitehall.

Mr. Wedgwood Benn remarked that where possible buildings had been erected on cheaper sites. For instance, the Stationery Office was being put up on the South side of the river. They would be defeating the object they had in view in concentrating the public services if they dispersed the buildings in the manner suggested.

The various votes were agreed to.

THE INTERNATIONAL
EXHIBITION.

The "International Society of Painters, Sculptors, and Gravers" should surely change its title, or the title of its exhibitions, for, except for the loan of a picture by Matthew Maris, this is entirely an English exhibition, some painters with foreign-looking names being practically English artists. And, in fact, a note to the catalogue informs us that the present exhibition is intended to illustrate "the most independent and progressive elements of contemporary landscape in Great Britain." Are we to presume, then, that the notable names omitted are not "independent and progressive" landscape painters? Or perhaps they are too independent.

However, the result is that this is the pleasantest and most enjoyable exhibition that the society has held, for it is in figure painting that the eccentricities and uglinesses of the ultra-modern school of painters are mostly exemplified, and we are glad this time to escape them. The collection at the Grafton Gallery contains quite a number of interesting and clever landscapes. Some of them are by deceased artists; among these are seven of Watts's small landscape studies, of great interest as examples of the impressions of landscape by a great artist who was primarily a figure painter, and one large upright landscape by him, which we think we remember once at the Royal Academy, a work singular and striking in composition, and puzzling in colour, for it is entitled "Green Summer," and green is just what it gives no impression of. There are also some large Venice water-colours by the late Arthur Melville, in his effective impressionist style, full of brilliant suggestion in colour, but with the architecture (as is too often the case with painters of effects) very badly treated; the Salute church, which is prominent in two of them, is barely recognisable. Another picture of his, "The Storm," is a powerful glimpse of effect, but in its manner it looks painfully like a chromolithograph, or a work painted for reproduction in colour.

Among the important landscapes is a fine one by Mr. Hughes Stanton, "Mountain Road in Provence," in his usual style of building rather than painting a landscape; "A Surrey Mill," by Mr. Bertram Priestman, who can be broad and powerful without losing coherence; and a large landscape by Mr. Walter Russell, "The Great Heath," the general power of which is much spoiled by the confused and apparently careless painting of the foreground. Mr. W. Rothenstein paints nature's building effectively in his cliff picture, "Nature's Ramparts"; and Mr. Hill and Mr. Sydney Lee deal effectively with the pictorial aspects of man's building, the former in "Charing Cross Railway Bridge," the latter in "The Barbican Gate," a picture which we seem to remember in more than one exhibition. Mr. Peppercorn, in his fine bold sketch, "A Surrey Hillside," may be congratulated on having discovered that there is light and colour in nature, and that she does make trees of an inky black. Mr. Sauter has realised a fine effect of shimmering sunlight in "The Avenue." Among other points of interest in the exhibition are a small collection of the landscapes of the late Mr. Charles, all fine and forcible in composition though somewhat spoiled by a dry, unsympathetic method, some of Mr. Greaves's Whistler-like effects, and some very good pictures by the late Arthur Lemon, a painter whose works are of more value than was recognised in his lifetime.

The sketches and studies in the long gallery are not very interesting, and some of them are quite too slight to be worth exhibiting. But, as a whole, the exhibition is one that can be visited with unmixed pleasure, which has not generally been the case with the International Society's displays.

TRADE AND CRAFT.

"More Daylight for Dim Interiors."

The most obvious thing about the business quarters of big cities is that the congestion of tall buildings causes an enormous number of dim interiors. If an auctioneer or an estate agent has to dispose of or to find a tenant for a business building, he is happy if he is able to announce with some degree of approximation to the truth that there is "a well-lighted interior" toward; in which case, however, his ideas on the efficiency of the illumination are likely to prove far more optimistic than those of the applicant for the "keys to view." When they twain meet on the spot, each will insinuate, more or less politely, that the other's vision needs attention from the ophthalmologist, which is a word that should not be carelessly thrown about in the semi-obscure. There would be the less need to trouble the expert with the formidable designation if early recourse were had to an effective means of conducting daylight artificially to dim interiors from which it is artificially, though accidentally, kept out. Messrs. Pilkington Brothers, Ltd., of St. Helens, devoting very careful attention to the subject, ascertained that many rooms remain dark and gloomy because the light enters at such an angle as to reach only the small space around the window. Now, it occurs to us that it is for a very similar reason that one's eyesight may become dim. In such a case, the expert with the sesquipedalian appellation will recommend correction for astigmatism, or for some other structural defect of the *néo-Grec* style. He will advise the adoption of glasses. These being acquired and duly adjusted, the patient's gratitude for being permitted to see clearly is tempered with regret that he lost so much pleasure and profit through not resorting earlier to the expert with the horrific name. This moral seems to be applicable to the too tardily treated dim interiors of buildings. The windows of a building being its eyes, the possibility of correcting their visual defects seems to be a very reasonable proposition. It ought, indeed, to be much less difficult to correct the visual defects of a building than those of the infinitely more delicate structure of the human eye. Messrs. Pilkington, in effect, supply the eyes of a building with "spectacles," which effectually correct their vision. The analogy must not be strained. The points of difference are quite obvious, although the essential principle is pretty much the same in each case. You do not see *through* Messrs. Pilkington's glasses, which are prismatic. They are manufactured in three different angles, to be used according to the position of the windows to be filled, so that every ray of light available is diverted horizontally, securing the even and natural illumination of the whole room. How this is done is very lucidly explained in an illustrated pamphlet bearing the title which heads the present notice. The system is of peculiar value in directing light to the interiors of shops where the lower part of the front window is used as a show-case excluding the light; or in banks and similar premises where window screens are necessary.

SOCIETIES AND INSTITUTIONS.

South Wales Institute of Architects.

The annual general meeting of the above Institute was held at Cardiff on June 2nd. The change of title from the Cardiff, South Wales, and Monmouthshire Architects' Society to the South Wales Institute of Architects was confirmed. The hon. treasurer submitted his annual report and accounts, which showed a steady increase in membership and a satisfactory financial position. The retiring president (Mr. G. E. Halliday, F.R.I.B.A.) was again unanimously elected. Messrs. E. W. M. Corbett, F.R.I.B.A., and John G. Groves, F.R.I.B.A., were re-elected vice-presidents; Mr. Harry Teather, F.R.I.B.A., hon. treasurer; Mr. E. H. Fawckner, F.R.I.B.A., hon. auditor; Mr. Edgar Down, F.R.I.B.A., hon. librarian; and Mr. J. A. Sant, hon. secretary. Messrs. Cecil Wilson, David Morgan, Chorlton James, Llewellyn Smith, J. W. Rodger, and H. Sesom Hiley were elected members of the council.

Architectural Association of Ireland.

At the last meeting of the Association the officers for the ensuing session were elected as follows: President, Mr. Geo. L. O'Connor; vice-presidents, Messrs. A. M. Reid and F. Sparrow. Committee—Messrs. P. L. Dickenson, N. G. Leask, A. G. C. Millar, H. J. Lundy, C. H. Mitchell, J. E. Burke, R. O'Brien Smyth, J. M. Mitchell, and L. Gieron. Hon. secretaries, H. Auberry and J. J. Robinson. The President announced that the annual excursion would be held early in July, the venue being Liverpool, and that Professor Reilly, of the University, had kindly offered to act as cicerone.

The Surveyors' Institution.

The forty-fourth annual meeting of the Surveyors' Institution was held last week, the Hon. Edward Gerald Strutt (who had been elected president for the ensuing year, in succession to Mr. W. E. Horne, M.P.) presiding. The annual report, read by Mr. Alexander Goddard, the secretary, showed that the membership had increased by 205 during the year, the roll now numbering 4,705, inclusive of twenty-four honorary members. Over 65 per cent. of the English and Welsh, and 95 per cent. of the Scottish candidates satisfied the examiners. The library had been enriched by a bequest of books by the late Mr. T. M. Rickman. The institution building had been enlarged and improved under the supervision of Mr. Paul Waterhouse, whose father was the architect of the building. The vice-presidents for the year were elected as follows: Mr. H. Chatfield Clarke, F.R.I.B.A., Mr. E. B. I'Anson, F.R.I.B.A., Mr. W. E. Woolley, and Mr. John Farrer, and there were added to the Council Mr. J. H. Sabin, Mr. J. Inglis Davidson, and Mr. J. McClure Clark.

York and Yorkshire Architectural Society.

Mr. H. E. Henderson, who has been for some time hon. secretary of the York and Yorkshire Architectural Society, and who is leaving for Nairobi, British East Africa, was entertained to dinner by the members of the Society on June 5th. Mr. A. B. Burleigh, president, during the evening was in the chair, and presented Mr. Henderson with a suit case from the members and referred in eulogistic terms to the work which he had done as their hon. secretary.

NEW BOOKS.

House Painting and Decoration.

The work of the house-painter is one of those things which are by no means so simple as they look, as the amateur soon finds out when, either to amuse himself or to save expense of labour, he makes an attempt on it. Serious work of the kind is best left to the tradesman who has been trained to do it; but as there are innumerable odd jobs of painting, whitewashing, or distempering, which will either be done by the amateur or left undone, the publication of a manual affording guidance to the unskilled is perhaps justified. Such guidance is not likely to increase very materially the volume of work done by amateurs, but will doubtless tend to improve its quality. The "Popular Guide" to house painting and decoration which has been prepared by Mr. Arthur Seymour Jennings will doubtless, therefore, do more good than harm in giving sound advice and safe guidance to those who know little or nothing about house painting, especially since apprentices and learners come into this category. Architects also may find in it many useful hints as to methods and materials about which it is necessary that they should possess a certain degree of knowledge.

House Painting and Decoration. A Popular Guide. By Arthur Seymour Jennings. London: Thomas Tofts, 93 and 94, Chancery Lane. Pp. 132, 8½ in. by 5½ in. Price 2s. net.

The Technics of Painting.

This is a small elementary guide—a few score of pages—for students and others who have to learn what are the characteristics of good and bad materials in practical painting, which is a most important matter in an age when the materials of the painter's craft have to be taken on trust. Painting grounds, mediums, pigments, varnishes, etc., are succinctly dealt with, the information being essentially applicable to everyday work. The author combines the qualities of a practising artist with those of an instructor, and his primer can be thoroughly recommended.

The Technics of Painting. By George M. Battus. Glasgow: James Maclehose and Sons. Price 2s. 6d. nett.

New "Homeland" Guides.

The latest additions to the well-known series of guides issued by the Homeland Association are three dealing respectively with the Westward Ho! district (price 3d. nett), a larger book giving full details of the "West Country"—Somerset, Dorset, Devon, and Cornwall (price 1s. nett), and the town of Reading (price 3d. nett). All three contain short descriptive accounts of local features of interest, together with particulars of situation, population, cost of living, etc. The publishers' offices are at 15, Bedford Street, Strand.

"The Town Planning Review."

The most important articles in the current issue of "The Town Planning Review," the journal of the Department of Civic Design of the School of Architecture of the University of Liverpool, are "Town Planning in Australasia," by Mr. Charles C. Reade, assistant secretary of the Garden Cities Association, who presents several views and plans showing the lay-outs of Adelaide, Sydney, and Auckland, which are all on "the prosaic checker-board model"; "The Monumental Qualities in Architecture," by Prof. C. H. Reilly, a paper read before the Irish Architectural Association, leading off with the characteristic observation that "on all sides we seem agreed

that the chief weakness of our modern architecture lies in its lack of the qualities we somewhat vaguely sum up in the word 'monumental'; and a short but interesting "Introduction to the Planning of Modern Italian Towns," by Professor S. D. Adshad, who illustrates his notes with a series of interesting views. This number begins the third volume of the "Review," and contains, as a new feature for continuation, examples illustrating notable features of English towns, the object being to show what has been accomplished in the distant or immediate past, containing suggestion for present-day use. The illustrated "Chronicle of Passing Events" is not the least valuable feature of a publication that is ably fulfilling an important mission.

THE LIGHTING OF THE HOUSE
OF COMMONS.

The following report to the First Commissioner of Works regarding a proposal to substitute electric light for gas in the Debating Chamber of the House of Commons has been issued as a White Paper, which is signed by Dr. E. Treacher Collins, F.R.C.S., L.R.C.P., who says:—

"On April 26th, 1912, I, together with Dr. Parkes, visited the Debating Chamber at the House of Commons and inspected the present arrangements for lighting it with gas, and the proposed new arrangements for electric lighting, in order to see if the latter were in any way likely to be injurious to the eyesight of members of Parliament.

"I found that the proposed electric lighting is to be effected by groups of three metal filament incandescent lamps, enclosed in a holophane globe, which is placed over a square pane of ground glass having an amber tint, and an ornamental pattern on it.

"(a) Ultra-violet rays may produce irritation of the eyes; they are to a great extent cut off by the passage of light through glass, and are completely cut off by glass of an amber tint.

"The rays from the electric lamps at the House of Commons will be filtered by passage through three layers of glass, (i.) that covering the lamp itself, (ii.) the holophane globe, (iii.) the ornamental pane of glass. The ultra-violet rays will be cut off by the amber colour of the latter. There is, therefore, no fear that the eyesight of members of Parliament will be affected by ultra-violet rays.

"(b) An amount of illumination equal to one candle foot is the minimum amount usually considered requisite for reading purposes. I was informed that the amount of illumination on the benches with the present gas lighting is four-fifths of a candle foot and that the same amount or more, as I should think desirable, can be obtained with the electric lighting.

"The amount of illumination in all parts of the Debating Chamber is not the same. The illumination from the roof is supplemented on the back benches by lamps fixed to the pillars in front of them. These do what I was told was required of them, i.e., light up the faces of members so that they can be seen by the Speaker. They are not, however, situated in the best position to enable members on the back benches to read. For this purpose it would be desirable that the light should come from behind them.

"(c) Uniformity of illumination. Variations in the intensity of illumination at its source so that there are glittering or glaring points is often found to be a source

of discomfort to the eyes. In the squares in the roof of the Debating Chamber I found the illumination to be more uniformly diffused and freer from points of a glittering character when they were lit by electric light than when they were lit by gas. This is accounted for by the dispersion of light which is produced by the holophane globes around the electric lamps."

THE STANDARDISATION OF
CATALOGUES.

At a meeting of the Junior Institution of Engineers last week, Mr. Arthur Bourne gave a lecture on the "Standardisation of Engineering Catalogues." He pointed out that, although the initiation of the movement for the standardisation of trade literature had its birth several years ago, manufacturers both in this and other countries seemed slow to move definitely in the matter, and it would appear that after all it would have to be left to private enterprise to invent and produce a satisfactory system whereby the chaotic conditions under which manufacturers were at present compelled to introduce their productions to the notice of consumers could be finally eradicated. Manufacturers had not been slow to realise the very great benefit accruing from scientific and systematic advertising in the technical and daily Press; why then should not a little more care, science, and system be brought to bear on the extremely important question of catalogue production upon which so much money was spent? Under existing conditions it was really difficult to know how to file catalogues, and of the many systems in vogue he doubted if any was really satisfactory.

He advocated not only the adoption of a standard size, but also the confining of one article to one catalogue. Manufacturers seemed at the present time to be devoting a considerable amount of attention to export trade, but in his opinion the large amounts spent annually in the despatch of elaborate and costly catalogues abroad was for all practical purposes wasted. What buyers abroad welcomed was literature that gave not only detailed illustrations, but also full and complete information, such as net and gross weights, shipping measurements, code words, and approximate prices, so that if necessary a quotation could be given without having to refer home. It was really surprising what a large percentage of catalogues failed in this respect.

In conclusion the lecturer pointed out that, although the systematic treatment of this complex subject was not without many difficulties, yet, the great need and desire for immediate reform being established, the engineering profession would universally welcome a practical system of dealing with trade information in their offices.

OBITUARY.

M. Raoul Larche.

The French sculptor M. Raoul Larche died on Tuesday, June 4th, from injuries which he had received on the preceding Sunday, when he was knocked down by a motor car. M. Raoul Larche was born at Saint-André-de-Cubzac (Gironde) in 1860. He was awarded the *medaille d'honneur* for sculpture at the Salon in 1910, and one of his best works, "Violettes," has been placed in the Luxembourg. M. Raoul Larche was an officer of the Legion of Honour.

THE STRUCTURE OF STA. SOPHIA.

SERIOUS QUESTIONS AS TO ITS STABILITY.

THE CHURCH OF STA. SOPHIA, CONSTANTINOPLE.

AS stated in this journal a few weeks ago, the structural stability of the great church of Sta. Sophia at Constantinople is very seriously questioned—so much so that, without extensive reparation, it is declared, the dome will not hold together for more than another twenty years. This being the case, it is opportune to give an exact account of the construction of the building, more especially as, among our illustrations, we are able to include as the Centre Plate in this issue a fine isometric drawing by the well-known French architect M Prost, who, together with an Italian architect, made an examination and report on the building two or three years ago, by request of the Turkish Government.

The Church of Sta. Sophia was erected by the Emperor Justinian A.D. 532-7, on the site of one which had been built by Constantine the Great, and afterwards destroyed by fire. The task of superintending the erection of the existing church was entrusted to two celebrated architects—Anthemius of Tralles, in Asia Minor, and Isodorus of Miletus. Wishing to avert from it the fate of its predecessor, the Emperor gave instructions that the new building should, so far as possible, be rendered fireproof. But, unfortunately, it was less easy to guard against another equally serious element of danger, and twenty-two years after the dedication the eastern portion of the dome was shattered by an earthquake. It was speedily rebuilt, 25 ft. being added to its height; while the buttresses, which had originally been carried no higher than the springing level of the great arches, were raised to the present height.

Records also exist of repairs to the supporting arches in the ninth and tenth centuries, and at a date still more recent the

dome itself was again fractured by an earthquake.

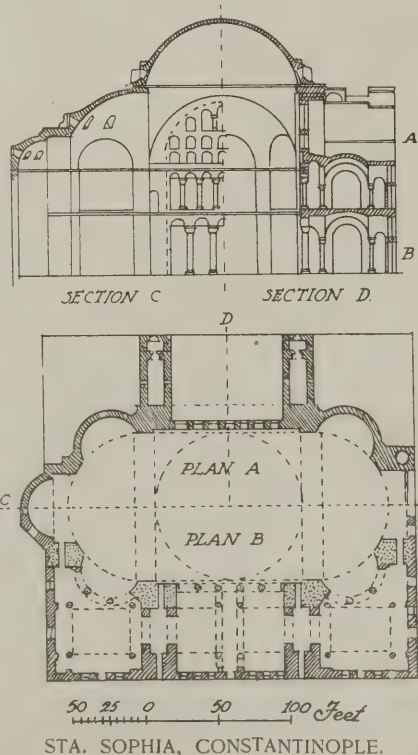

After the fall of Constantinople, A.D. 1453, the church was divested of its arrangements for Christian worship, though its general structural character remained unchanged.

In the construction of the church the pendentive, in its simplest yet most complete form, is the agency for the conversion of the square plan below into a circular one

above, in order to form a fitting base from which to spring the dome (see Fig. 2).

The general scheme of the church seems to have been a Greek cross with a central dome. This idea, however, was not carried out in its integrity, for, of the four arms of the cross, those on the north and south are screened off from the central space by arcades, which support galleries and clerestory walls, only those on the east and west, which are vaulted by semi-domes of nearly the same span as the central dome, being comprised in the body of the church. Opening out from these latter are smaller extensions, or exedrae, the aggregate presenting an unobstructed area exceeding 24,500 sq. ft., covered by a graduated system of domical vaulting, springing from one common level of 74 ft. from the floor, and rising higher and higher, until it culminates in the grand central dome.

This extensive system of vaulting is mainly dependent on eight massive piers, each occupying an area of nearly 500 sq. ft. and carefully constructed of large dressed blocks of hard stone. The piers for the support of the central structure rise from the angles of a square, but are so arranged as to leave openings to the main extensions of 103 ft. in width, and on the north and south sides of only 74 ft. The square plan of the central compartment is obtained by forming a break of 3 ft. in each pier; this defines the internal angles and provides the necessary planes from which to spring the four great arches that receive the pendentives. On the east and west these arches support the dome, and are brick barrel vaults about 13 ft. on the soffit and 6 ft. in thickness; they are open to the large hemispherical vaults that abut against them. The corresponding arches on the north and south sides are not the real supports for the dome, but are chiefly for the purpose of giving uniformity to the pendentives. They

STA. SOPHIA, CONSTANTINOPLE.

THE CHURCH OF HIA. SOPHIA, CONSTANTINOPLE. A STUDY OF ITS STRUCTURE, AS EXISTING. BY H. PROST

have a width of 3 ft. on the soffit, which agrees with the break in the piers (Fig. 3).

The demand for increased strength on these sides arising from the absence of semi-domes has been met (1) by limiting the span of the supporting arches; (2) by giving them a depth of nearly 16 ft.; (3) by forming the curve for a considerable height from the springing with horizontal courses, thus still further reducing their span; and (4) by filling them in from the springing line, with clerestory walls, 4 ft. thick, resting on the arcades.

It should be mentioned that these walls are flush with the inner face of the supporting vaults, thereby concealing the awkward line of the arches inside, and leaving about 12 ft. of the soffit exposed on the outside; but Messrs. Lethaby and Swainson, in their fascinating account of the building, have ventured the plausible hypothesis that the enclosing wall was originally placed further back, on the plane of the outer face of the vaults, whereby a gallery would be left inside the church. This *may* have been so, yet, granting the waste of space lamented by M. Choisy, we can hardly regret it, in view of the peculiar charm afforded by the restraining character of the enclosing walls, in relation to the never-ending wonder of the vaulting.

The circle developed by the pendentives is at the height of 135 ft. from the floor, and has a diameter of 103 ft. On the top is laid a wide course of stone, with a projecting cornice; this gives a firm and even bed for the dome, the inner face of which is set back from the edge of the circle about 2 ft.; by this arrangement the pendentives are somewhat relieved and a gallery is provided, "on which the man who cared for the sacred lights could walk fearlessly and trim each in turn."

The primary motive of the selection, for the dome, of a segmental rather than a semicircular section was probably the desire to limit its weight. But, in addition to this, by springing the dome more gradually from the pendentives, the pleasing effect of the interior is no doubt improved. The internal diameter is 107 ft., and the clear height from the springing 47 ft.

Resting on the circular bed of stone before mentioned are forty piers, 9 ft. 6 in. deep and 3 ft. 6 in. wide, spaced regularly all round the circumference. The intermediate spaces are arched over, at the height of about 16 ft., to receive the remaining portion of the dome, the shell of which is gradually reduced in thickness to 2 ft. at the crown.

The brilliant idea of piercing through the abutment, while virtually maintaining its continuity, and thus providing a range of windows at the base, appears in Sta. Sophia not only fully developed but as the earliest known instance of its kind, and though lacking the simple grandeur of the solitary eye of the Pantheon, yet, as a method of lighting, it is decidedly superior; it must also contribute in no small degree to that appearance of buoyancy for which the structure is said to be remarkable.

The ribs, with a slight projection on the inner face of the dome, in no way affect the homogeneity, to which quality may doubtless be attributed the extension of the fractures by which the structure has at various times been imperilled.

The materials employed in the construction are well-burned bricks, 2 in. thick, with mortar joints of nearly the same thickness; in the lower part of the dome the bricks are about 27 in. square; at the crown they are 2 ft. square. The joints do not radiate from the centre, but have a much flatter inclination, an expedient which

THE DOME OF STA. SOPHIA, CONSTANTINOPLE: DETAILS OF ITS CONSTRUCTION.

would make it possible to carry up most of the work without continuous centering. This method was also adopted for the supporting arches. The curved face of the pendentives is corbelled over in brick, but the cavity behind is filled in with a light stalactical material, used in its natural state, without any preparation.

In turning the pendentives and the dome, it is probable that a method still practised in the East was resorted to. A pole, equal in length to the radius of the proposed hemisphere, is so attached to a central post that it can be swung in any direction, and thus made to describe the curves at every course of their height. The whole of the exterior of the dome is covered with lead, which serves as an effectual protection to the magnificent mosaic of the interior.

It is worthy of note that generally throughout the building, the supporting arches are merged as much as possible into the vaulting by forming a skewback all round the arch, either close to the soffit or only a few inches above it, as in the pendentives of the dome, and the external angles are always rounded, to turn the tesserae of the mosaic. In this way all

harsh lines are obliterated, the vast expense appearing to be covered with a continuous, yet undulating, tissue of gold.

It must be obvious that in a pendentive dome, a matter of the first importance is the limitation of its weight, and towards this end every available expedient, short of the omission of the crown, seems to have been resorted to in Sta. Sophia; the segmental form, the tenuity of the shell, the method of lighting, even the material employed, all contribute to that object. Still, the fact remains unaffected that the stability of a dome elevated on pendentives and arches of wide span can be effectually secured only by an extensive system of abutment applied to the substructure.

In the Pantheon the supporting wall has mass sufficient to withstand both the vertical and the horizontal pressure. But the Byzantine builders, wholly dispensing with walls under the dome, and extending the building on all sides, left only the four piers to sustain the vertical pressure, while for resistance to the horizontal thrust they relied on the walls and vaulting of the surrounding buildings. Thus in Sta. Sophia the thrust of the immense arches on the

STA. SOPHIA, CONSTANTINOPLE: A CAPITAL.

north and south is fully withstood by the semi-domical extensions; while to meet the enormous thrust of those on the east and west huge buttresses are raised against the piers, whence they extend across the aisles and galleries to the outermost walls of the building, a distance of 50 ft. These seeming obstructions, which are carried up their full projection nearly to the level of the platform surrounding the dome, are built hollow and pierced with wide vaulted openings on the level of each floor, thus preserving the continuity of the aisles and galleries. M. Choisy has shown that these buttresses and the square platform now surrounding the dome were at one time much lower on the north and south, so that the curve of the dome protruded beyond the platform, and the extrados of the supporting arches was exposed. The buttresses and filling-in over the arches were raised to the present level to render the abutment more nearly equal to that on the east and west. (Fig. 4.) Had the idea of the Greek cross been carried out in its entirety, and semi-domes raised on all the four sides, the statical properties of the structure would have been perfect, and all necessity for the clumsy expedients resorted to precluded. Yet, even as it is, the Church of Sta. Sophia is a remarkable instance of the skilful production, from the slenderest materials, of the grandest architectural effects and of perhaps the finest combination of domical vaulting the world has ever seen.

DERWENT VALLEY WATERWORKS.

Some Details of Construction.

At a meeting of the Surveyors' Institution held at Buckingham, Mr. Bernard Everard read a paper on "The Works of the Derwent Valley Water Board." He said that the watershed utilised formed part of the Peak District, and for the most part was moorland, comprising an area of nearly 32,000 acres. All of this area lay at a greater altitude than 580 ft. above Ordnance datum—26,800 acres above 1,000 ft., and 11,600 acres above 1,500 ft. When the present works were completed there would be practically no houses left above those reservoirs which would supply the towns. Geologically, the valleys were

in the Yoredale series of shales and sandstones, many of the hills being capped by mill-stone grits. The water was decidedly soft, only about two or three degrees of hardness.

The Howden and Derwent reservoirs, now nearing completion, were together expected to yield about twenty million gallons a day—13 1-3 million gallons for supply and 6 2-3 million gallons for compensation water. The total storage capacity of the two reservoirs would be 3,940 million gallons, and the area of the watershed draining to them 13,220 acres. There was a good deal of discussion as to whether the dams should be constructed of masonry or should be earthen embankments, and the question of stability in case of landslips, of which a number of ancient traces were found in the district, had to be considered. Masonry was finally decided upon. Work on the Howden Dam was started in November, 1901. The excavation in the centre of the valley was taken 70 ft. below the bed of the river, but even at this depth the ground was not sufficiently watertight, the beds of shale and sandstone being crushed and contorted. It was therefore decided to excavate a narrow trench 6 ft. wide until a watertight stratum was reached. This trench, which had to be taken right across the valley for a further depth of 55 ft. below the main foundation, was afterwards filled with cement concrete, and formed a watertight curtain wall below the dam. In 1908 a doubt had arisen whether the hillsides were watertight; consequently headings were driven, and on both sides of the valley broken beds of shales were met. Wing walls had therefore to be built extending 3,000 ft. on each side of the reservoir. These wing walls were constructed up the valley, not in line with the main dam. Wing walls were also necessary in the case of the Derwent Dam, but in this case it was thought better to carry them straight into the hillsides, and this was done for a distance of 500 ft. at each end. A curtain wall was also constructed below the main foundations of the dam. The interior of each dam was composed of Cyclopean rubble, large rough blocks of stone surrounded by cement concrete, in the proportion of about 45 per cent. of stone to 55 of concrete. The

dams were faced on each side with dressed stone, and the joints on the upstream face were caulked with neat cement.

The water was conveyed through an aqueduct from the Derwent reservoir to the filter beds at Bamford, the Sheffield supply being taken off by means of a tunnel through the hills, from a point just south of the Lady Bower Brook. The water, after passing through the filters, flowed some twenty miles to a service reservoir at Ambergate. This reservoir regulated the supply to the towns if for any reason the line to the north was interfered with. It was covered, and would be divided into three parts, only one of which was now being constructed, work on the other two being deferred until they were likely to be required. The portion now under construction would contain 28,000,000 gallons. The walls and floor were built of concrete, faced with asphalt, and the roof of concrete and steel girders supported by brick piers. The top water level, which regulated the pressure on the supply mains, was 640 ft. above sea level. The main aqueduct consisted of tunnel, cut and cover, and pipes. The tunnels and cut and cover, which were made large enough to take the whole ultimate available supply, were formed of concrete with a lining of blue bricks, circular in section, having a diameter of 6 ft. 3 in. The pipes, of cast iron, were 45 in. in diameter, and were used where the aqueduct came under pressure in crossing valleys and low ground. Easements had been acquired for laying three lines of pipes, but only one line was now constructed to convey the first instalment from the Howden and Derwent reservoirs.

The Board's works terminated at Langley Mill, and thence the Nottingham Corporation had constructed their own pipe line to their reservoir at Cockpit Hill. The Corporations of Derby and Leicester had a joint main 40 in. in diameter as far as Coxbench, within four miles of Derby. At this point a branch main conveyed Derby's share of the water to their reservoir at Little Eaton. The aqueduct constructed by the Board—now reduced to 33 in.—continued south to a point just north of the River Trent, near Sawley.

The author said that the portion of the works carried out for the Corporation of Leicester had been constructed under the supervision of his firm. The Leicester aqueduct, commencing near Sawley, crossed over the River Trent and passed south of the west of Loughborough and through Beaumanor Park to Hallgates, a distance of about fourteen miles. The pipes were for the most part 32 in. in diameter. At Hallgates, a service reservoir to hold 2,000,000 gallons existed for the present supply to the town, and another reservoir of equal capacity had now been made. He believed that the line of pipes from Ambergate to Hallgates was the longest "siphon" in England, being 29½ miles. The length of aqueduct from Derwent to Leicester was about sixty-seven miles. Through the valley of the Trent two lines of pipes had been laid, although one was sufficient to convey Leicester's share of the first instalment. Owing, however, to the high pressure on the mains, which reached 240 lb. per sq. in., to the fact that the gravels were there always saturated to within 3 ft. of the surface, and to the difficulties of access during periodical floods, this course was considered necessary in order to safeguard a continuous supply.

The most interesting work on the Leicester section, and possibly along the whole line of aqueduct, was the bridge which

carried the pipes over the River Trent. This bridge, which was built of steel, was of the bow-string type, and crossed the river in one clear span of 220 ft. at a height of 17 ft. above the ordinary water level. It was designed to carry four lines of steel mains, two for immediate use, and two for future requirements. The superstructure was carried upon brick and concrete foundations enclosed in cast-iron cylinders, which were first sunk by the aid of compressed air to the solid marl, at a depth of 21 ft. or 22 ft. below the river level. Started in the summer of 1906, it took some fifteen months to erect, and cost nearly £9,000.

In conclusion the author mentioned that the works of the Board were estimated to cost about £6,000,000, and if to this were added the other works carried out by the four corporations the total expenditure would be £7,100,000.

BUILDING INTERESTS IN SOUTH AFRICA.

(Specially written by our South African Correspondent.)

JOHANNESBURG, May 6th.

National Federation Congress.

In fulfilment of my promise I may now be allowed to devote some space to the important Congress of the National Federation of Building Trade Employers in South Africa. It was the eighth annual conference, and was endowed with both an historic and a business interest. In point of fact, it was an anniversary meeting after a lapse of seven years in the very hall in which the inaugural congress had been held. In this cycle of time there has been undreamt-of and unparalleled progress, and there has been, also, one consistent and well-directed effort to maintain the high status and prestige of the Federation.

New Constitution.

The corporate life of the Federation has undergone a process of evolution towards a more completely fused condition, and the adoption of the new constitution must mean a more perfect readjustment of its organising powers and influence. The main lines and general principles of the Federation will still be followed, but the administration will be greatly strengthened, and it will be better armed with all the vital essentials to meet any emergency with which the Federation may be confronted in the future. One never knows when labour troubles may arise. In South Africa, as elsewhere, sometimes the workman's fancy lightly turns to thoughts of strikes, and it is well to be prepared to meet unjust demands for reduction of hours and revision of wages.

An Extended Agenda.

Naturally, a country which has spent close upon £10,000,000 in buildings in the course of four years affords abundant scope for earnest reflection on industrial subjects associated with the trade. Congress this year, therefore, was provided with a somewhat extended agenda; in fact, there were no fewer than twenty-nine items down for attention. Some of these, of course, were of the hardy annual type, but others touched untrodden ground, and were of much public as well as trade interest.

Indenture of Apprenticeship.

Amongst the first subjects was the important one of indenturing apprentices. This is a subject that should be taken in hand by all Chambers of Commerce and other commercial and industrial associations in the country. Boys here, with their love of play and sport, are apt to

think it beneath their dignity to learn a trade of any kind; as, however, every civilised country is striving for industrial expansion to increase its capital and provide profitable employment for its people, boys everywhere should be encouraged to adopt a trade career. It is certainly gratifying to know that technical schools throughout the country are doing much to foster this aim.

Industries Commission.

The report of the Industries Commission rightly was subjected to adverse criticism, as a most unsatisfactory document, that even the Government is ashamed of. The whole subject of industries will be dealt with soon at a well-organised Congress of Manufacturers and men engaged in all kinds of trade and commerce.

Conditions of Contract.

The Federation keeps on striving for uniformity in conditions of contract throughout the Union. That this will ultimately be brought about seems within the range of possibility. The matter is no doubt one of great difficulty in South Africa, but this is also the case in other and older countries, where builders are found pegging away year after year for the much-longed-for desideratum of a set of conditions of contract as nearly perfect as is attainable in the varying circumstances.

Afforestation.

In looking over the report, I am glad to see that the Port Elizabeth Master Builders' Association have taken up the question of afforestation in South Africa. The remarks made should be well weighed by the Government, as they are of national and commercial importance, especially with reference to timber required for the building and manufacturing trades, and the increasing scarcity of suitable timber from the foreign markets.

Coloured Skilled Labour.

Another subject on the agenda that calls for passing reference is that of coloured skilled labour. The Federation have kept this subject before them during the past year, but Ministers are slow to act, and very little progress has been made. It is a subject, however, of such importance to the building trade that it cannot be allowed to be kept in the background, and for that reason it was well that it was at least referred to.

Builders Visiting Europe.

Quite a number of South African master builders are visiting Europe this year, and several have already left. As the National Federation here is affiliated to the National Federation of Building Trades Employers of Great Britain and Ireland, it is to be expected that they will take advantage of the opportunity to be present at the summer meetings in Nottingham in July.

PROJECTED INTERNATIONAL BUILDING EXHIBITION, LEIPZIG.

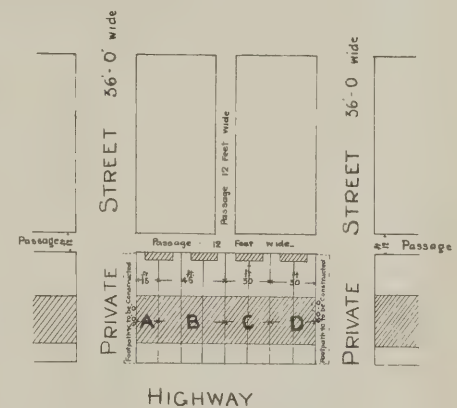

An international building trades exhibition is arranged to take place at Leipzig from May to October, 1913. The classification of the exhibits is as follows: Division I.: Architecture, eight groups—comprising town-planning, roads and bridges, underground constructions, interior planning, industrial art, furniture, architectural painting and sculpture, gardens and parks, cemeteries and funerary art, construction and maintenance of monuments, protection of scenery and objects of interest. Division II.: Not yet arranged. Division III.: Materials of construction, their manufacture and appli-

cation, twenty groups—comprising stone, wood, ceramics, artificial stone, mosaic, concrete and reinforced concrete, facings, isolating materials, metallurgy, glass, installations, heating, lighting, electricity, wall-coverings, house-painting. Division IV.: Machines, utensils, and appliances used in building, eight groups. Division V.: Not yet announced. Division VI.: Hygiene of dwellings, fabrics, and streets, protection of workers, welfare of workers, protection against fire, ventilation, disinfection, baths, cleansing, etc., six groups. Division VII.: Not announced. Division VIII.: Testing of materials of construction, technical demonstrations. The offices of the exhibition are at Leipzig, Gottsched-strasse, 22.

ENQUIRIES ANSWERED.

New Footpaths, etc.: Apportionment of Cost.

REGENT writes: "An urban authority resolved to apportion the expenses of private street works under the whole of the powers contained in Section 10 of the Private Street Works Act, 1892. If the foot-

paths, etc., alongside the gables of houses owned by A and D were constructed (see sketch), what would be a reasonable proportion of the cost of the work to charge against owners of property B and C?"

—There is no doubt as to the legal power of the sanitary authority to charge the owners B and C with an equitable portion of the cost of making up the footpaths flanking the properties of A and D, and it is a question of fact for the justices to determine what proportion is rightly chargeable to those owners. Personally I am of opinion that the benefits to the houses of B and C from this particular part of the works are so slight that they would be well advised to resist any charge save of a very nominal character. F. S. I.

Question of Building Line.

SUBSCRIBERS write: "We have deposited with the local Council plans for a house and shop to be erected on a corner site. In one road the proposed structure would be level with the building line of the adjoining properties; but as regards the return front, we consider that we are entitled to build to a line drawn between the property on the other side of the cross road and a building immediately in our rear, thus gaining an advantage of four extra feet. The Council, however, require us to set back the building on this return frontage to the building line of the house in the rear, namely, to a distance of 8 ft. Are we legally compelled to do this?"

—This enquiry raises the very nice legal point as to whether the words of the Acts,

"in the same street," can apply to a street intervening in a cross direction. I do not think such a case has yet been decided. I advise that you accede to the Council's request and set back the whole of your new building 8 ft. X.

Validity of Tenant's Notice.

W. H. E. writes: "A three years' tenancy agreement is terminable on September 29th next by either party giving six months' notice. Are calendar months or lunar months implied? Would a notice dated March 29th last, but posted at 9.45 p.m. on the following day and received on April 1st, be valid and in order?"—Calendar months are implied by such a proviso. I am of opinion that your notice is bad, because the full 183 days' notice has not been given, but it is a matter which admits of some argument and it is to be regretted that the tenant has put himself in such an equivocal position. I advise the parties to agree between themselves as to what should be done. F. S. I.

CORRESPONDENCE.

The Editors disclaim all responsibility for the statements made or opinions expressed by correspondents. Correspondents are asked to be brief and to write on one side only of the paper.

"Mystic Board of Trade Returns."

To the Editor of THE ARCHITECTS' AND BUILDERS' JOURNAL.

SIR,—In your issue for May 29th, Mr. J. H. Kerner-Greenwood says that foreigners send their goods to England and then tranship them to our colonies as English-made goods in order to gain the preferential tariff given on English-made goods. But, now, have not all foreign-made goods sent to England to have printed clearly on each individual parcel the name of the country in which they were produced? Therefore, where will the Custom House officers in our Colonies be to pass goods sent from England, mind you, but with the name of the foreign country in which they were produced printed clearly on them outside, as English-made goods, and thus give them the preferential tariff. I think they will not quite do this. I hope that Mr. J. H. Kerner-Greenwood will kindly reply to this.

W. S. N.

[It does not seem necessary to trouble Mr. Kerner-Greenwood for a reply, the means of overcoming the assumed difficulty being so very obvious.—Ed.]

A BUILDER'S AFFAIRS.

Before Mr. Registrar Brougham, on Friday last, the public examination was held of Mr. James Fryer, who had carried on business as a speculative builder, at 110, Strand, W.C., under the style of Pink, Fryer, and Co., and was adjudged bankrupt on May 11th. The statement of affairs showed gross liabilities £83,313, of which £10,496 was expected to rank for dividend, and assets valued at £7,286.

A balance-sheet prepared in June, 1906, showed that he then had a balance of capital in his favour amounting to £29,000. During 1909 and 1910 he built offices and shops in Bedford Row and a hotel over the Piccadilly Electric Railway Station, and he expected the latter to produce a surplus of £4,000, which would become available for his creditors. He attributed his insolvency to the depreciation of house property in London and inability to dispose of his buildings at Hampstead.

The examination was ordered to be concluded.

COMPETITIONS.

New Council Offices, Portland.

Eighty-seven designs have been submitted for this building, which is to cost between £3,500 and £4,000.

The first premium (£50) has been awarded to Messrs. Spier and Bevan, of Cardiff, and the second (£10) to Mr. Ernest E. Fetch, of London.

LIST OF COMPETITIONS OPEN.

JUNE 24. KING EDWARD WELSH NATIONAL MEMORIAL.—Sketches for two sanatoria, one in North Wales, 150 beds, the other in South Wales, 250 beds. On preliminary sketches, not more than six architects will be selected to send full plans and details. Particulars from Secretary Welsh National Memorial Offices, Newtown, Montgomeryshire.

JUNE 26. BATHS, BIRMINGHAM.—Twenty guineas for second, ten guineas for third design. Apply, Superintendent Engineer, Kent Street, Birmingham.

JUNE 28. TOWN PLANNING, HALE.—Premiums of £50 and £25 are offered for a town-planning scheme. Address, Council Offices, Hale, Cheshire.

JUNE 29. ESTATE DEVELOPMENT, REIGATE.—Premiums of 30 guineas and 10 guineas are offered for schemes for the laying-out and development of Reigate Lodge Estate. Address, the Town Clerk, Reigate.

JUNE 30. TOWN HALL, ETC., PADIHAM.—Premiums of £40 and £20 are offered for designs for town hall, baths, etc. Particulars, Mr. J. Gregson, A.M.Inst.C.E., Surveyor's Office, Padiham. [See communication from R.I.B.A. Secretary, in our issue of May 15th, p. 508.]

JULY 1. NEW OFFICES FOR THE PORT OF LONDON.—Limited to the six architects selected in the preliminary competition. [See our issue of April 10th, p. 370.]

JULY 5. ADDITIONS TO HOSPITAL, CONISBROUGH.—Doncaster and Mexborough Joint Hospital Board invite competitive designs (in sepia or Indian ink) for additions to their isolation hospital. Apply, H. M. Marshall, Clerk to the Board, Union Offices, High Street, Doncaster. [The time has been extended from that formerly announced.]

AUGUST 6. FIRE BRIGADE STATION, CARDIFF.—Cardiff Corporation invite architects to submit designs and estimates in competition for a fire brigade station proposed to be erected in Westgate Street, Cardiff. The Corporation have appointed Mr. A. Marshall MacKenzie, A.R.S.A., F.R.I.B.A., to act as assessor. Particulars on deposit of two guineas (returnable) from J. L. Wheatley, Town Clerk, City Hall, Cardiff.

AUGUST 30. SAXON SNELL PRIZE.—Fifty guineas, with medal, for essay on hospital construction. Apply, Sanitary Institute, 90, Buckingham Palace-road.

SEPTEMBER 30. NEW BUILDINGS, UNIVERSITY COLLEGE, DUBLIN.—The Governing Body of the University College, Dublin, invite architects to submit designs for new college buildings. Competition is limited to architects living and practising in Ireland. Mr. H. T. Hare, F.R.I.B.A., has been appointed the assessor. Applications, accompanied by cheque for two guineas (returnable) to J. W. Bacon, M.A., Secretary and Bursar, 86, St. Stephen's Green, Dublin.

OCTOBER 1. KING EDWARD MONUMENT, OTTAWA.—Sketch models, in plaster. Particulars, Secretary, Public Works Department, Ottawa.

THE RESTORATION OF TATTERSHALL CASTLE.

What Lord Curzon Proposes to Do.

On the occasion, on Wednesday last, of the historic fireplaces being restored to Tattershall Castle, Lord Curzon of Kedleston (who has been mainly instrumental in saving them) spoke of his plans of restoring the Castle. Seven months ago, he said, he recovered the building. He had less than twenty-four hours to do it. He came down by the morning train, saw the place, and by five o'clock that afternoon he sent a telegram to say that he would buy the Castle to recover it for the nation. The fireplaces had gone, and the fear was that they would be taken out of this country and sold in America. That would almost have been a national scandal. It was then that he decided to attempt to recover the fireplaces, and he acknowledged a great debt of gratitude to many rich and cultivated men who helped him in that task. He could not have undertaken it himself, having already undertaken the responsibility for the Castle, but Mr. Shuttleworth and Captain Weigall, their member of Parliament, and other friends of his, interested either in that place or in antiquities, helped him.

Lord Curzon went on to describe what was proposed to be done both with the fireplaces and with the Castle. He said that under the direction of Mr. Weis, than whom no man living in England was more competent to do justice to the task, they were excavating the whole of the Castle area in order to discover as far as possible what was there before. While the keep was almost the only structure that remained, it was only part of the ancient Castle, and all about the inner walls were buildings of various descriptions constituting one of the greatest mansions in that part of England. They knew from records that Lord Cromwell, who built that place, rode abroad with 120 men and lived in that Castle with 100 personal retainers. That meant that he was surrounded with great circumstance of pomp and position, and one of their first objects was to ascertain as far as possible what lay on the space of ground on which they stood, not with a view of restoring it—he did not propose to rebuild that which was gone—but with a view of discovering the conditions of life in those days. But there were certain things he would restore, and first and foremost were the moats. There were relics of the old inner moat surrounding the Castle. He hoped to restore both the inner moat and the outer one, which ran outside and was an additional protection, and he proposed to restore, for everybody to see, a picture of this great fortified mansion as it was 445 years ago. The works would occupy certainly a year, and perhaps longer. With regard to the fabric itself, they would first fix a lightning conductor, so that the Castle should not be struck by lightning again. Then they would begin from the roofs and restore the whole interior of the Castle, putting in four floors. Then the mantelpieces would be placed in their niches, the mullions and traceries of the windows put back, and glass put in, and though he would not hope to live there himself, for to tell the truth life under those conditions was somewhat uncomfortable, yet the Castle would be there for anyone to see, and it would be a type and memorial of the sort of conditions under which great noblemen once lived.

Lord Curzon of Kedleston, and those whose hearty co-operation he so generously acknowledges, are to be heartily congratulated on the happy issue of their prompt and patriotic action.

Elementary School Planning.

HE principal requirements in the construction of elementary schools may be grouped under headings of site, arrangement of plan for convenient working, lighting and ventilation, sanitary provisions, and economy of cost. The small book on the subject by Mr. Philip A. Robson* does not actually group the requirements

under this precise division, but all the requisites of elementary school building may be referred to one or other of those headings. Mr. Robson's book, which is very concise, and wastes no space either in matter or illustrations, seems to aim at summing up in a practical manner the present position of the subject. Although the subject of "Training Colleges" is placed first in the title, the plans and the text are much more largely concerned with elementary schools, which form, in fact, the most important and difficult part of the subject, as they are much more numerous than training colleges, and they present a more difficult problem of combining efficiency with economy of space and construction. A training college is a type of building admitting of more variety of plan, and in which there is generally less demand for economy of cost. But the elementary school is a special type under special conditions.

The book is rather fragmentary in arrangement. Its main feature is a reprint of a lecture by the author on the hygienic planning of schools, delivered at meetings of the Royal Institute of Public Health; then comes a chapter on "Recent Elementary Schools in Derbyshire," by Mr. Widdows, the architect to the Derbyshire Education Committee; and after this, remarks on higher elementary, secondary, and technical schools, followed by the author's notes on the Report of the Departmental Committee on the cost of elementary school buildings. The remainder of the volume is made up of a large number of illustrations, including plans of elementary and other schools, and photographs of some exteriors of school buildings and of some of the rooms fitted with special appliances in technical schools. Photographs of this last kind, however, are not of much practical use; plans and sections of the special furniture are much better. The plans of Derbyshire schools are, of course, those of Mr. Widdows. For the rest we are left in doubt as to whom to attribute the plans, except that one or two are named as by the author. We may also observe that a good many of the plans have no north point given, although aspect is of the greatest importance in school planning.

We may say a word first as to the contribution of the Derbyshire school architect, Mr. Widdows, one of whose plans, "A Derbyshire Elementary School," we reproduce (Fig. 1), as these plans are all on the system of cross-lighting which Mr. Widdows upholds. There may be something to be said for it, though so far as cross-ventilation is concerned, that may be obtained without cross

lighting, which in the main is not advantageous; it necessarily puts some of the pupils with a right-hand light. With his cross-lighting Mr. Widdows is naturally somewhat indifferent as to aspect. As he says, rooms lighted on both sides are sure to get sunlight for some part of the day; consequently one is not surprised to find that none of his plans are decorated with a north point, and that in his secondary school plan he employs the four-armed radiating plan, with the hall in the centre (in this case a north point is given, some of the classrooms being lighted only on one side). This radiating plan is very convenient for economising corridor traffic and inspection, but it has no other recommendation. It was once supposed to be the type of plan for prisons and lunatic asylums, but experience soon led to its disuse. There are some good practical suggestions in his paper, however. Fig. 1 shows how a central corridor of communication may be made wide enough to act practically as a central hall, with doors into open verandahs, which ensure adequate ventilation when required; and he describes and illustrates another scheme of plan, in which the classroom doors open on to covered verandahs, so that the classrooms open really into the outer air, the floors to be a step up, and the door to be outside the step and to shut against it, so as to preclude draught underneath the door, a provision which shows an eye to actual facts of working. His method for avoiding the freezing of the w.c. supply cisterns in winter, by placing them all within a warmed central passage (Fig. 2), into which also the traps of the closets discharge, is ingenious, and ought to be practically efficient. We may also note with approval his remark that "cupboards are worked in as part of the structure, and cumbersome pieces of ugly furniture are avoided

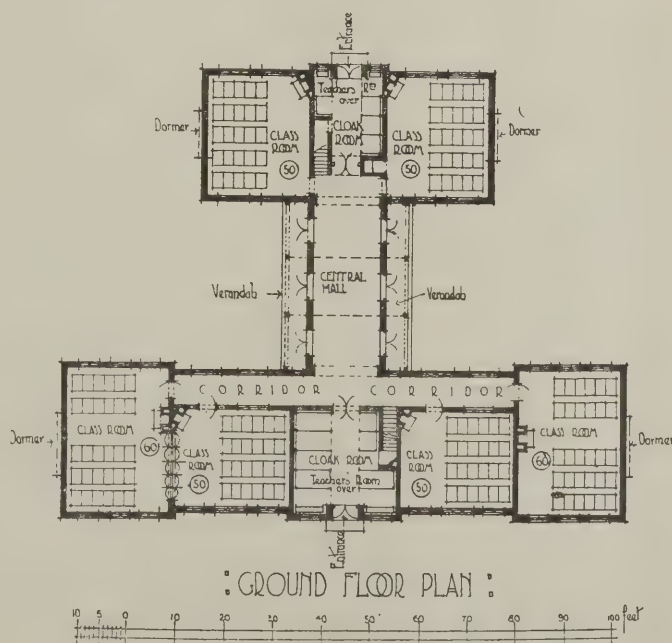

FIG. 1.

A DERBYSHIRE ELEMENTARY SCHOOL.

* School-Planning; being a practical treatise on the Planning of British Training Colleges and Schools. By Philip A. Robson, A.R.I.B.A. London: Nicholson-Smith; 1911. Price 15s.

thereby." They need not necessarily be "ugly," but structural cupboards arranged in convenient recesses are much better than loose furniture for the placing of which no special provision has been made.

To return to the author's preliminary lecture, which is the real kernel of the book, all the remarks about the conditions of site for a school are excellent, and should be carefully studied, and we may specially emphasise the recommendation that before a site is purchased the opinion of an experienced school architect should be taken. He may see fatal objections to the proposed site which have not occurred to the intending purchasers, who may thus be saved from an injudicious expenditure at the outset. In regard to staircases, it is pointed out that if the building is a long one the staircases should not be at the extreme ends; also that "external iron staircases, which are very rarely used or tested, will prove to be

DERBYSHIRE TYPE OF CONVENIENCES.

sources of accidents, and in the case of day-schools they indicate bad planning. If considered necessary, then another staircase should have been built in the first instance."

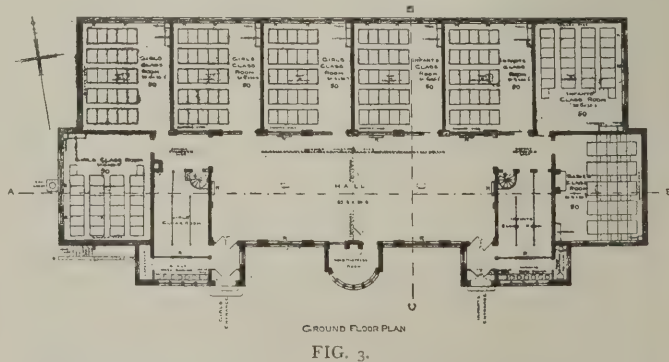

In regard to classrooms, the author says that (as is usually admitted) left-hand light is "important," and if this is impossible, right-hand light is the next best. It is, but it is a very bad second to left-hand light, and we should be inclined to put it more strongly, and say that left-hand light is indispensable. If it cannot be arranged for, then the plan is bad to begin with in its general layout. In the upper of the two plans for "an elementary school in three departments," given on page 50 of the book, the position of teacher and class should have been reversed on one side of the plan, so as to get left-hand light on both sides; owing to neglect of this, the classrooms on one side get left-hand light, while those on the other side have to put up with right-hand light. There seems to be no reason why the positions should not have been reversed in order to avoid this defect. In regard to the aspect of classrooms we cannot quite agree with the recommendations made, which are hardly decisive enough. The author recommends that where there is a central hall its longer axis should run north and south; "this will allow the classrooms, placed on two or three sides of it, to get the sun during some part of the day, with their windows facing south, south-east, and south-west." Now, we consider that for a classroom south is as bad a light as it is for a painter's studio or an architect's drawing office. It is all very well in winter, perhaps, but at other seasons of the year a south aspect means constant trouble with the sunshine; permanent heat and discomfort when there is steady sunshine, and still more trouble on those days, frequent in this climate,

when there is bright sunshine frequently veiled by passing clouds, producing a constant irritating change from too much light to too little, or what appears to be too little by contrast. It is all very well to say that health depends on plenty of sun; so in a sense it does; but no one wants to work in bright sunshine. East, with perhaps a little south in it, is the best classroom aspect; then the room gets warmed by the sunlight in the early morning, and the direct sun is off it when lessons begin; and west is the next best, for lesson time is generally over before the rays of the western summer sun become inconvenient.

The question of the central hall is, as the author says, a rather troublesome one. It appears that in Germany and in America daily assembly of the whole school is not the general rule; in England it is. In the two countries just named the central hall, therefore, has not the importance that it has with us; it is often relegated to the top floor. In England it is necessary that it should be of easy access from the classrooms. To have the latter opening directly out of the central hall is an economy of space and walling, but with the drawback that it is noisy if the hall is used for exercise or drill for part of the classes, while others are occupied in the classrooms. Some heads of schools prefer it, as rendering the school as a whole very easy to keep under inspection; but in general we should say that it is better to have it separated from the classrooms by a corridor.

In regard to cloakrooms the author lays down that they should never be passage-ways to the school-rooms or classrooms, but should be entered from a corridor. The "never" is perhaps too emphatic; there does not seem to be any absolute reason why they should not; in a confined site it makes for compact and economical planning, as seen in the plan of Fig. 1. But though it is better to have a separate corridor of access, it is necessary that, in one sense, the cloakroom should always be a passage, i.e., it should be planned with an entrance at one end and an exit at the other end, so that the pupils who have deposited their cloaks or coats should go straight on to the exit at the other end, and not be jostling others by a return to the entrance door. The author expresses this opinion emphatically in the text, but he has not carried it out in his own plan of the St. George's, Hanover Square, Schools, where the cloakroom certainly has two doors, but they are both at the same end—both, in fact, being entrance doors. The children may, it is true, enter by one door, go round the end of the central screen, and come up the other side of it to the other door; but will they do so? The cloakrooms should be so planned that entrance at one end and exit at the other is the obvious and necessary course, and can hardly be avoided: otherwise there will be confusion.

We give as Fig. 3 what seems to be one of the best plans in the book, that on page 63 for "an elementary school for 200 girls and 200 infants on one floor." The classrooms all have left-hand light; it would have been preferable if the majority of the classrooms had not been quite so much due north in aspect, though that is a great

ELEMENTARY SCHOOL FOR 200 GIRLS AND 200 INFANTS
ON ONE FLOOR.

FIG. 4.

PHILIP A. ROBSON, A.R.I.B.A., ARCHITECT.

deal better than due south, except for the babies' classroom, the only one which has that light, and the only one in which it is suitable, for the babies are engaged in regulated play rather than work, and for that sunlight is no disadvantage. The head mistress has a cheerful bay-windowed room facing south. The cloak-rooms, and the method of access and egress from them, are very well planned. In this case the classrooms open directly out of the hall; in the case of a school for girls and infants only there is less objection to this, as they are not so noisy as boys.

Mr. Robson concludes his lecture or essay by the observation, in which we heartily concur, that the ideal school should have a beauty and order of appearance—a "eurythmy," as Vitruvius calls it (only the author spells it "eurythmy," which is surely incorrect); "to build schools like glaciers in angularity and eccentricity, or resembling barracks in their barrenness, is to deprive the children of what may rightly be called their birth-right of beauty." That is the great fault of the French *lycée* buildings, which, with their cast-iron type of architecture, look like education-mills, and perhaps only too closely symbolise the methods of instruction carried on in them. A school, especially for the very young, should have something home-like about it. In connection with this point we give, as Fig. 4, the exterior view of the author's St. George's Schools, a building which fairly answers this ideal, and is certainly far more attractive than the French type of school architecture.

We observe that the author more than once takes the opportunity of having a dig at the plenum system of ventilation, and at mechanical ventilation generally. We quite agree with him that it is a mistake to train children to think that fresh air is disadvantageous, and that windows must be kept shut, a lesson which all the children of the poorer classes are certain to learn at home, for everyone who has had any experience in visiting homes of that class must have observed how difficult it is to persuade the inhabitants to open their windows; and domestic servants, who come mostly from the same class, are just as bad. But when the author speaks of those who want plenum ventilation as "fad-dists," he is going a great deal too far. It is impossible to keep the air changed as often as it ought to be, in large schools, without mechanical ventilation. We have a very distinct recollection (though we cannot now give chapter and verse for it) of a published series of experiments made a good many years ago in Scotland, in which the state of the air of a large schoolroom was scientifically tested after so many hours of occupation under "natural ventilation," and after the same number of hours of mechanical ventilation; commencing in each case with the state of the air before the room was occupied. The statistics were such as should have convinced

the most sceptical that in the matter of keeping the air of a room free from impurities the natural ventilation was almost nowhere, so to speak, in comparison with the cleansing effect of mechanical ventilation. The latter is expensive, no doubt; but except in the case of small schools the result will be found to be worth the expenditure.

Architects and Furniture.

A TOO characteristic discussion took place the other day at the Middlesex County Council, on the occasion of a recommendation from the County Buildings Committee that Mr. J. S. Gibson, the architect for the new County Hall, should also be commissioned to design the furniture and fittings, and to superintend its construction, at a fee of $7\frac{1}{2}$ per cent. on the amount expended. The fee is too small, because the work to be done is far greater in proportion than the work to be done for the usual 5 per cent. on the cost of a building. The outlay on a building includes a great deal of work, such as walls and flooring considered *en masse*, for which there is no actual designing to be done by the architect, but the cost of which all goes towards increasing his 5 per cent., so that over the whole he is fairly though not extravagantly remunerated. But in the case of furniture and fittings it is all design on the part of the architect, and for such work, unless a fixed fee were agreed upon (which would be far better), the architect would really not be adequately paid at less than 10 per cent. on the outlay. Whereupon up gets a certain member of the Council and declares that it is absurd to ask an architect to design furniture, when there were eminent firms who would submit designs free of cost and make the furniture required! He was supported by two other members. What strikes one most in such discussions is the ignorance about everything that is going on in the world of art; apparent total ignorance of the fact that architects are constantly asked to design furniture; that the best modern furniture has been designed by architects, and that the method of the supply of designs by commercial firms, employing craftsmen whose names are concealed and who get no credit for their work, is at the root of all the unsatisfactory and commonplace furniture and fittings that are so frequently produced. Of questions of art in small things there is here a strange oblivion, though no subject in connection with art has been more often and more publicly discussed of late years. The Buildings Committee evidently, and very rightly, considered that their architect's building ought not to be spoiled by the introduction into it of shop furniture, which might probably be quite out of keeping with the building. Fortunately the chairman, who earnestly exhorted the Council to have confidence in the Buildings Committee and to support its decision, succeeded in getting a majority in favour of the committee's report, and the ridiculous amendment on it was not carried.

The Piccadilly Facade.

IF there were wanting a dramatic proof of the need of such a society as the London Society for preventing the architectural disfigurement of London it would be found in the terms of the letter addressed to "The Times" by Lord Plymouth and Sir Aston Webb, on behalf of the society, in regard to the piece of vandalism which appears to be in progress in Piccadilly. The Piccadilly front of the Piccadilly Hotel, designed by Mr. Norman Shaw, with its range of columns standing free in the upper storey, is one of the finest and most effective pieces of modern street architecture in the world, but it is incomplete so far, only one of the end wings which flank and support the colonnade having been built at the time, owing to some legal delay in getting possession of the property at the east end of the site. Some time ago, however, we had the disastrous news that the eastern wing, or what would take its place, was about to be rebuilt by the owners with entire disregard of Mr. Shaw's design, of which it ought to form the completion. A good deal of indignation was expressed at this, and subsequently a

rumour was spread that this intention had been abandoned, and that the wing was to be carried out in accordance with the design of the western wing. Now it appears that a building is actually in process of erection which is to ignore Mr. Shaw's design altogether, and practically, therefore, to ruin its effect, and no authority over London building seems to have the power or the will to put a stop to it. If this destruction of a great architectural design is allowed to go on, merely on commercial grounds, it is one of the most deplorable things in regard to public architecture which have ever happened even in London, and that is saying a good deal. Is any further and more authoritative step to be taken in the matter? Mere protests in "The Times" are of no use; obviously those concerned with the building care nothing about them, as they do not even take the trouble to reply or to try to make a case for themselves. How is London ever to be architecturally improved, if private owners are to be allowed to deface an important architectural design merely because it suits their convenience to do so?

The Fate of the Old G.P.O.

IT is stated that the old General Post Office buildings, St. Martin's-le-Grand, E.C., are to be entirely demolished, to make way for a new building in which certain administrative offices of the constantly expanding business under the control of the Postmaster-General are to be accommodated. Sir Robert Smirke's dignified if dirty pediment and pillars will be greatly missed, as they gave to the district a certain sedately classical character, which, however, has within recent years lost much of its impressiveness by the erection of adjacent big buildings of incongruous character. The old Post Office was erected during 1825-29, on a portion of the site once occupied by the monastery of St. Martin's-le-Grand, which was founded about the middle of the eleventh century; and it is recorded that in excavating for the Post Office buildings traces of an Early English crypt were discovered. This section of the City lost much of its distinctive character by the demolition of Christ's Hospital School, on the site of which the new General Post Office has been built of reinforced concrete, and there are those who, for the same more or less sentimental reasons, lament the earlier demolition of the Gaol of Newgate, which, though gloomy and grimy in the extreme, held the observer in a sort of horrible fascination; and hence they will have it that George Dance's building was much finer than the Sessions House, designed by the late Mr. E. W. Mountford, which has taken its place. No matter how excellent the building (and we are optimistically hoping for the best) that shall arise on the site of the old G.P.O., a full and fair appreciation of its merit may only be possible to a new generation that is undistracted by recollections of Smirke's Classic façade.

Proposed New Richmond Bridge.

THE time seems to have come when the necessity for a new bridge over the Thames at Richmond cannot be denied, and one may support it with the more ease of mind because the authorities most nearly concerned seem to have given up the idea of destroying the present bridge, and with it much of the beauty of Richmond, in order to build a wider one. Some years ago this was all the talk, and many seemed to regard the destruction of the bridge with entire equanimity. And when the subject was first discussed there was really no adequate ground for saying that the bridge was insufficient for the traffic. Its approach at the town end was no doubt always bad, but until very recent years the traffic over it was not large. It is the coming of the motor car, and more especially the motor bus, that has made the difference, and has also made the question of the approach and the gradient more serious. The approach is bad, independent of the gradient, because it is in line with no main street, but is at a sharp angle out of a street, which has itself a considerable gradient. What is now proposed is the formation of a tolerably wide road continuing the

line of Red Lion Street, and carried across the river at the point where there is the eyot called Corporation Island. As far as the road-line is concerned this seems a perfectly good scheme.

We only hope that the scenic character of that beautiful reach of the river will be fully considered, and that it will not be spoiled and defaced by the erection of a girder bridge. To place that kind of bridge there would be to entirely alter the character of the view at that point. There is every opportunity, every suggestion indeed, in the site itself, for a really picturesque and fine stone bridge, with piers on the Surrey bank and on the island and a wide arch over, and a smaller arch spanning the river from the island to the Middlesex side. Arches of different span, arising out of the configuration of the ground, add much to the picturesque character of a bridge. One has only to look at the old bridge over the Dee at Chester to see that. With such a bridge as we have indicated, and the beautiful existing bridge retained, the improvement in the road-line across the river can be made without spoiling the beauty of the Thames at Richmond, and without destroying Paine's fine bridge, which could remain; whereas, with the introduction of a girder bridge the charm of the spot would be gone.

It is foolish in these matters to shut one's eyes to obvious facts, and all reasonable persons will at once recognise that the existing bridge at Richmond is not only inadequate, but dangerous for traffic and foot-passengers. Therefore, some relief must be provided. And it is by erecting a new bridge at the foot of the Hill that this relief should be secured. It is well to bear in mind, too, that when the proposal to build a bridge across the Thames, in place of the then existing ferry, was first put forward, the intention was to take the line of route now suggested, and this scheme, the proper one, was only negated by the selfish obstinacy of a landowner on the Middlesex side who would not agree to the roadway being cut across his land.

London Building Trades Agreement.

IN the comments which we have made from time to time on the demands of the London building trade workers for better conditions, we have consistently held that, so far as it was possible to foresee the upshot of the negotiations with the employers, there was always a strong probability of a peaceful settlement of the difficulty. That view, we are greatly gratified to record, has been fully justified by the event, as it was announced last Wednesday that the carpenters had decided by ballot to accept the concessions offered, and that the rest of the trades, and the labourers, would doubtless fall into line. It will be remembered that the men had asked for an increase of threehalfpence an hour. The odd—the very odd—halfpenny obviously represents what in courtesy may be termed a factor of safety, or margin of graceful concession, or compromise—the time-honoured hand-selling that seems to be indispensable to any sort of bargaining, the one side being, by the inveteracy of the custom, almost compelled to ask more than it will accept, because of the tacit assumption that it will follow an ancient custom of allowing discounts, or of providing for the higgling of the market, or that it will observe the perhaps more modern practice of giving the other side a luck-penny (or luck-halfpenny), which softens defeat and "saves the face" of the defeated among their supporters. In the present case the three halfpennies are being dealt with in three several ways; one is to be conceded immediately, another is to fall due next March, and the third does not materialise, but, by a pleasing fiction, may, nevertheless, be regarded as a consolation prize for the employers. Whether settlement of the dispute in this spirit of conciliation betokens confidence on the part of the employers that business will sufficiently improve to stand the extra cost of labour that has been thus imposed upon it, or whether, on the other hand, they felt that a strike supervening on depression would be the last straw, is a problem that one would rather not attempt to solve. At any rate, it is extremely gratifying to know that at least we are to be spared what would have been a desolating extension of the current epidemic of strikes.

THE LITTLE THEATRE, NEW YORK.

The accompanying illustrations show "The Little Theatre" which has been erected in New York from designs by Messrs. Ingalls and Hoffman. It is a very pleasant building, modelled on what is known in America as Colonial work, and, like "The Little Theatre" in John Street, Adelphi, is delicately sumptuous throughout.

The theatre has been designed expressly for the production of a certain class of plays in which a small caste only is required, and whose fullest effect is obtainable by the placing of seats so comparatively near the stage that no detail, either facial or vocal, may be lost. The architectural treatment is fully in keeping with this idea. The exterior is a radical departure from the usual opulent splendour we are accustomed to see displayed on theatre fronts. It is distinctly domestic in charac-

Auditorium from Stage.

THE LITTLE THEATRE, NEW YORK.

INGALLS AND HOFFMAN, ASSOCIATED ARCHITECTS.

ter, and one is immediately attracted by the detail of the Order employed, and of the entrance door itself, with its fan and side lights, and the delightful stone tablet above the opening.

Within we find the auditorium (measuring not more than 40 ft. from the front of the stage to the back of the rear seats) treated as a rather monumental Georgian room hung with tapestry, the place of tapestry being taken by decorative paintings in quiet colours. The ceiling is very flat, adorned with plaster work in low relief, and the lighting is by crystal chandeliers and candelabra side lights. The seats are comfortable, and the rise is very carefully calculated to give a full view from every seat to the perfectly flat stage. The latter, 30 ft. in diameter, is one of the very few examples where the Japanese idea of a revolving platform has been incorporated into an American theatre, permitting quick setting of scenes requiring little depth. In other ways the stage is typical of the best modern methods, in that full room for very

high drop scenes is given, and the lighting is perfectly well worked out.

One of the unique features of the theatre is a lounge in the basement which is really used. The room is also designed in Georgian style, and is extremely well furnished.

It is a place where not only a few of the thirsty males in the audience can go between the acts, but a large part of the whole assemblage is gathered there to be entertained by an orchestra of five. The smoking room is placed adjacent to this lounge, and it is another charming little Georgian room, although so small as to be inconvenient for any large number.

The exterior of the theatre is carried out in red brick, limestone, wood painted white, and ironwork painted a flat black; the façade being artificially illuminated by a system of indirect lighting. The auditorium has a seating capacity of 300, and is finished in birch of a deep walnut brown tone. The seats are upholstered in brown leather, the curtains are of a Gobelins blue, and the carpet is grey.

MAGAZINES AND REVIEWS.

In the "Burlington Magazine" Mr. Lionel Cust writes a short summary of the scheme for the enlargement of the British School at Rome, which he concludes with some rather pointed questions. In the first place, he asks whether the State and national support of the fine arts at home is so substantial that any large sum can be spared annually for the maintenance of an institution in a foreign country? Then, is it absolutely agreed that modern Rome is a suitable art centre for the development of the young British student? To the first of these questions one would be apt to reply in the negative, only there is the consideration that the existence of the enlarged British School at Rome may react in awakening a little more interest in art at home. To the second question we should certainly reply in the affirmative. There is enough at Rome to stimulate the artistic imagination, and that is what is needed. Then he puts a third question—whether archæology and art, the ends of which are opposed (archæology looking to the past and art to the present and future), can possibly be cared for equally in one institution under a Council which meets in another country. That is a question which we have already touched upon; the British School at Rome is referred to as an institution parallel with the French School; that is to say, it is to be an art school; and yet it is to be presided over, as far as one can see, by two archæologists. That will never do. In the same issue Mr. Aymer Vallance commences a series of illustrated articles on "Early Furniture," and Mr. A. Romney Green contributes the third article of his series on "The Principles and Evolution of Furniture-Making." The article of this month is rather politico-social than artistic; it is a restatement of the theory of William Morris—that art dies as soon as the worker loses his personal interest in the work and becomes a factory hand. The mediæval craftsman, who worked with his own hands, was, as Mr. Green says, a well-paid and important person; in the present day the well-paid and important person is not the actual worker but the middleman who engages him. The only remedy for this is for the public to insist on dealing with and paying the actual craftsman and ignoring the middleman. It is a remedy that would necessarily work but slowly, but it would be certain in its ultimate results.

The "Architectural Record" (New York) is an interesting number. It devotes

THE LITTLE THEATRE, NEW YORK.

INGALLS AND HOFFMAN, ASSOCIATED ARCHITECTS.

one article to a description and illustrations of the old Palazzo Davanzati at Florence, which appears to be the only ancient palace left standing in one of the ruthlessly, but perhaps unavoidably, modernised streets of the city. The façade in the Via Porta Rossa, is that of a building erected somewhere about the close of the fourteenth or beginning of the fifteenth century, a plain, stern stone front with three storeys of segmental-arched windows with very little reveal, and an open colonetted loggia at the top. In the ground storey are three large arches filled up with cross-barred doors (probably not original), and mezzanine storeys are indicated by two rows of small square grated windows. The whole aspect of the building has that curious mingling of Gothic feeling with a presentment of the Renaissance spirit which characterises so many Italian buildings of the period. An article on "Portland, Oregon," dealing with "the transformation of the city from an architectural and social view-point," gives the idea that American architecture is not showing to advantage in this transformation, the new buildings illustrated being for the most part very heavy in style and devoid of architectural charm. "Building a House of Moderate Cost" is the subject of an article by Mr. R. C. Spencer, jun.

He suggests that the feeling for those who desire a constantly rising standard of architectural taste should be, "We care not who designs our churches, court-houses, and marts of traffic, if we may really *design* the homes of the people." This is an exaggeration, of course, but it emphasises a side of architectural development the importance of which is often underrated, and we quite agree with the writer that the satisfactory architectural treatment of a house of moderate cost is really one of the most difficult of problems. It is rather sad to read that "as soon as it becomes known that you are about to build a house you are liable to be pestered by architects looking for a job." Is it really as bad as that in the States? Then Mr. J. T. Tubby contributes a very practical article on "Thrifty Draughtsmanship: The Economies Possible in Work." We recommend this to the notice of draughtsmen; it contains many good suggestions. One very simple and obvious one is to return each instrument, when its use is interrupted, to a certain place, and have a place for it, so that the hand goes at once to it and one has not to waste seconds in discovering "where that bow-pen has got to." Standard scale sheets of drawing paper, with the scale printed on them, and a dot showing the centre in each direction

of the paper, may be useful. Parallel pencils we do not think of any use, as it is so difficult to ensure the two points being cut to the same angle; parallel pens, especially if set to a certain scale, are useful in survey drawing, for roads, and may be to a certain extent useful in architectural drawing. The writer suggests the value of having three or four reliable bow compasses permanently set, and marked, for 4-in. soil pipes, columns, round flue linings, etc., of whatever stock sizes are drawn repeatedly. The author suggests the vertical position of the drawing-board for free-hand drawing, and says it is much used in Germany; there are advantages in it, but a draughtsman would have to acquire the habit of it. When the writer says that for ordinary T-square drawing it is desirable to pitch the board as much as possible—"that is, to a point where the T-square, the triangle, the scale, and the tools just will not slide," we should have thought that a matter of mere common-sense which hardly demanded special notice. We will add, in this connection, a point which does not occur in the article; it is a convenience to have two or three pairs of hard-wood blocks of different sizes, thick enough to have a firm base, by using which as rests a drawing-board can be tilted to a greater or lesser angle as desired. A triangle is always firm on its base. In the description of the new museum of French art in New York, which it appears is to be assisted by objects lent by the French Government from time to time, there is an odd mistake in the title of a print called here "The Tuilleries." Not only is the name mis-spelt, but what the drawing shows is not the Tuilleries, but a view of the west aspect of the Louvre. The Tuilleries was no part of the Louvre; it was the cross block connecting the western ends of the Louvre galleries. The Tuilleries has no existence now. Its buildings were wrecked in the Commune, and subsequently removed altogether.

The "Nineteenth Century" contains an article by Mr. H. H. Statham, "At the Salon and the Royal Academy," in which, contrary to the general practice in exhibition criticisms, the sculpture is given the first place in the article; and at the Salon it is really the most important portion of the exhibition. As the writer remarks, it is too much the fashion, both with spectators and critics, in this country, to devote nearly all their time to the pictures and content themselves with a hurried glance at the sculpture afterwards. At the Academy the sculpture is forced into so subordinate a position that there is some excuse for this; but it is quite otherwise at the Salon, where the annual exhibit of sculpture numbers nearly a thousand works, many of them of great scale and importance. The writer urges that the Academy ought to give a larger space to sculpture in their annual exhibitions.

In the "Contemporary Review" Mr. March Phillipps, in his article on "The Gothic Ideal," harps on the same idea as that of Mr. Romney Green in the "Burlington Magazine." The Gothic ideal, he urges, is not in buttress, shaft, pointed arch, etc., but in the root principle that the manipulation of any material to the production of artistic work is the function of the man who works in the material and knows it. We may add that many architects know this perfectly well, and endeavour to act upon it, and that architects are not all the narrow-minded persons Mr. March Phillipps appears or professes to think. But in modern architecture there is another element which he does not seem to realise, viz., the complication of plan for

a special purpose; and "The Gothic Ideal" will never grapple with that by the craftsman process. It needs the central mind; in fact, the modern architect is actually in the position of a craftsman in the production of plan and section. Writers on art from what may be called a socialistic art point of view seldom or never see that if important modern buildings were left to be planned and carried out on Mr. Phillipps's "Gothic Ideal" theory, there would be an end of all good planning. But the article is worth attention.

The "Century" publishes an illustration of what is called (we know not why) "The Perry Memorial," which appears to be a memorial proposed to be erected "at Put-in-Bay, Ohio," to commemorate the battle of Lake Erie and the hundred years of peace between Great Britain and the United States. And what form does the reader suppose this memorial takes? A Doric column of colossal—we might say more than colossal—size, standing up against the sky, with a little kind of shrine built on the centre of the abacus; and at considerable distance to right and left of it two small columned temples; the whole on a low flat shore. It certainly looks impressive in the illustration, but it is a most extraordinary and not very happy use to make of the Doric column.

COMPETITIONS.

The Soane Medallion.

The attention of intending competitors for the Soane Medallion is called to the following modifications in the conditions:—

1. No restriction is placed on the size of the strainers; at the same time they should be of reasonable size.
2. The plans, sections, and elevations to be drawn to 1-16th scale.
3. A section through the front buildings up to and including the rail heads of the lines to be drawn to a scale of 8 ft. to an inch.
4. Plans of the upper floors and basement need not be drawn.

New Church, Carrington.

The design of Mr. Curtis Green, F.R.I.B.A., of London, has been selected in this competition. The cost of the church is estimated at £10,000.

PROGRESS WITH THE LONDON COUNTY HALL.

At a recent meeting of the London County Council the Establishment Committee was instructed "to expedite the completion" of the new County Hall, and to report immediately to the Council the steps they proposed to take in order to carry out this instruction. The Establishment Committee now report that the two governing factors at the present time are the dates of the delivery of drawings of the superstructure by the selected architect and the date of completion of the sub-structure of the central section. On the assumption that the selected architect will deliver the drawings of the central section at the beginning of July, and those of the southern and northern sections at the end of August, it is estimated that their examination by the official architect, the preparation of the quantities and the estimate, the invitation to firms to tender, and the execution of the necessary contract, will take approximately until the date of the completion of the central section of the sub-structure, namely, April 12th, 1913. Should it be found that the period required for the examination of drawings, the taking out of quantities and the like, can be shortened, special steps can be taken to complete the sub-structure at an earlier date. As to the erection of the superstructure, the Committee suggest that alternative tenders should be invited, say for three or two years, with a bonus for each week saved on the contract time. If the carrying out of the scheme be expedited in the manner suggested, the Committee are not without hope that the revised dates which they now submit may be improved upon. On present calculations the sections should be completed by the following dates:—Central section, April 12th, 1916; southern section, March 15th, 1916; and northern section, June 12th, 1915. The Committee also desire to correct the supposition that some restriction has been imposed on the spending of money required for the new County Hall. On the contrary, money has been voted as quickly as possible in order that the work may be pushed on with all despatch.

If the work is going to be furiously "hustled," the architects and the contractors are to be commiserated.

THE LITTLE THEATRE, NEW YORK: THE PROSCENIUM.

CORRESPONDENCE.

The Editors disclaim all responsibility for the statements made or opinions expressed by correspondents. Correspondents are asked to be brief and to write on one side only of the paper.

*St. Paul's Bridge and the R.I.B.A.
To the Editor of the ARCHITECTS' AND
BUILDERS' JOURNAL.*

Sir,—In the Annual Report of the Institute, which was submitted to members on May 6th, the Council called attention to their action in connection with the St. Paul's Bridge scheme.

In the House of Commons on June 14th, 1911, the Chairman of Ways and Means (Mr. Emmott) stated that the representatives of the Institute had "failed in doing their duty." I called attention to that failure at the meeting on May 6th, and the President refused to allow my remarks to be printed in the Institute Journal, which simply states that I "went on to criticise the inaction of the Council in not attending before the Committee of the House of Commons. In the circumstances I am not at all surprised at the ruling of Mr. Leonard Stokes, and I ask for the hospitality of your columns to state the facts and to quote a few comments upon the policy of the R.I.B.A. in connection with the most important scheme for the improvement of London that has been before the public for many years, a scheme that has frequently been referred to as one of "national importance."

The Royal Institute of British Architects presented a strongly-worded petition to Parliament against the Bill: it is printed in the Institute Journal of February 18th, 1911, and it is signed by Mr. Stokes, three other members of the Council, and the secretary. The following are extracts:

"Your Petitioners' Institute, as the only chartered body of architects in the United Kingdom, accepts and claims as part of its responsibility and public duty the function of tendering advice to the Government. The advantage to the community of having at its disposal the technical advice and experience of a body of experts is admitted on all hands."

The following are extracts from speeches delivered in Parliament on June 14th, 1911; they are taken from the Official Report of Parliamentary Debates, Vol. 26, No. 85, published by H.M. Stationery Office.

Mr. Mooney (Chairman of the Committee): May I inform the House very shortly what are the facts in this case? The Institute of British Architects petitioned against this Bill, and lodged their petition in the usual form. When the Committee sat the Institute did not think it worth while to appear before the Committee. As chairman of that Committee I expressed astonishment at the fact that the architects were not represented before the Committee, and I went out of my way to invite them to appear before us, and give us the benefit of their ideas. The invitation was mentioned in the London papers, but the architects never appeared before us. . . . I would have been far better pleased if the Institute of Architects had come before us and given us the official view of the scheme.

Mr. Morrell: Had the architects an opportunity of explaining their point?

Mr. Mooney: I said before, I personally invited the architects to come before us and they declined to do so. . . . When the Committee sat the Institute did not appear before them. They wrote to "The Times" and said the reason they

did not appear was on the ground of cost. I invited the Institute to send a representative before the Committee. The total cost to the Institute would be four guineas, yet the House of Commons is asked to-night to send this Bill back to the Committee in order to suit the Institute of British Architects.

Sir William Gelder: Why should the architects be required to spend £500 or £1,000 in opposing a scheme of this kind any more than any other class?

Mr. Mooney: If the Institute of British Architects had followed our suggestion they would have incurred no such cost; they could have come before the Committee and given their opinion.

Mr. Lamb: On this occasion the Chairman of the Committee invited them to come to the Committee, and yet they did not appear.

Lord Balcarras: I frankly regret the attitude of the Institute of British Architects. I am not in their confidence . . . from the knowledge I have of architects I think the hon. member opposite was very wide of the mark when he suggested that they did not place their case before the Committee simply because it would have placed a small expense on their personal pockets. I do not believe that.

The Chairman of Ways and Means (Mr. Emmott): Is it fair that the Committee should suffer because architects have failed in doing their duty? The Institute of British Architects did not appear before the Committee, although every chance was given to them to appear. No objection was made to their *locus*, and the chairman sent them a special invitation. I really think the hon. member for Brigg (Sir William Gelder) was hardly fair to the members of his own profession when he said it was a question of cost. I really do not think so meanly of the architects. If this is a matter of great public interest on which they feel so strongly, surely some of them would come forward and give evidence. . . . The architects had their chance and they did not take it.

Mr. Alfred Lyttelton: . . . He has actually said that because the Institute of British Architects failed to respond to the invitation of the Committee, London is for all time to be treated as if that evidence was not forthcoming and as if no other person could give it but the Institute of British Architects. Nothing could be more fundamentally wrong than that. The interest of the public is of great interest here. What has the public to do with the failure of the British architects to come before the Committee?

In consequence of the above strongly-worded comments I submit that a full explanation is due to the members of the R.I.B.A.

*The Newer Responsibilities of Architects.
To the Editor of THE ARCHITECTS' AND
BUILDERS' JOURNAL.*

SIR,—Referring to the fourth paragraph of the leading article in your last issue, it is surely, as you suggest, ridiculous that the building owner cannot dismiss his architect without the consent of the builder. I have not read the Official Referee's judgment in the case of *Minter v. Waldstein*, and cannot say whether Mr. Woodward has interpreted him rightly, but if so, it would be interesting to hear the arguments and cases upon which the decision rests.

In the first clause of the Articles of Agreement (R.I.B.A. Conditions of Con-

tract) the architect is described as "his" (the employer's) "architect." He is paid by the employer, and his only responsibility to the builder—or, rather, jointly to the building owner and the builder—is in the exercise of his judgment upon possible matters of difference between them. In signing the contract, the builder implies his acceptance of the architect in this capacity; but he does not pledge himself to accept any other architect the building owner may employ. Clause 3 of the "Articles" gives him the necessary protection against the subsequent employment of a different architect than that named in the contract.

With respect to the clerk of works, it is amazing that, in view of clause 7 of the conditions, contractors should so often plead his authority for deviations.

A. SAXON SNELL, F.R.I.B.A.

Plaster Reproductions.

*To the Editor of the ARCHITECTS' AND
BUILDERS' JOURNAL.*

SIR,—We note with pleasure your very appreciative note of Miss Casella's exhibition of plaster reproductions now on view at our galleries.

In writing his criticism of the bust by Mino de Fiesole, however, your critic appears to have overlooked the note we particularly printed in the catalogue to the effect that, in order to show the possibilities of the processes she employs, Miss Casella has in certain instances deliberately produced marble originals as wood, and vice versa. The Mino bust is one of the notable examples of this: deliberately incorrect treatment by Miss Casella. We should be obliged therefore if you could find space for this letter.

Per pro. The Medici Society, Limited.

ARNOLD FAIRBAIRNS, Director.

Grafton Galleries, London.

[If the above is the explanation, we think it was an artistic mistake to take what was originally a marble bust and imitate it in the likeness of a wooden one: for the technique of marble carving is necessarily different from that of wood carving.—ED. "A AND B. J."]

*Insulating Material for Hollow Walls.
To the Editor of THE ARCHITECTS' AND
BUILDERS' JOURNAL.*

SIR,—I note in your issue of May 29th the enquiry by "Ailsa" as to the best insulating material with which to pack either a hollow wall or a framed partition for the purpose of forming an effective cold-storage chamber, and the reply thereto by "G."

Both writers appear to be ignorant of Cabot's sheathing and insulating quilt regularly advertised in your pages. . . . Cabot's Quilt retains the separate air spaces indefinitely. The long ribbon-like fibres of ell-grass of which the quilt is made cross each other at every angle, and form within each layer of quilt innumerable minute cells of "dead" air, thereby making a wonderfully effective non-conductor.

"A."

A Housing Congress for Amsterdam.

An International Housing Congress is to be held at Amsterdam in September, 1913. It will consider the general question of cheap dwellings, inquire into the ways and means of ameliorating the conditions of rural housing, the sanitation of unhealthy areas or tenements, the question of overcrowding, and, finally, the problems of town-planning.

Supplement to THE ARCHITECTS' AND BUILDERS' JOURNAL, Wednesday, June 19th, 1912.

THE SHOP-FRONT PROBLEM.

Mr. Selfridge's Opinion.

In recent issues of this journal the problem of the design of shop-fronts has been discussed at some length. The architectural side of the question has been put forward with emphasis, but we have not been oblivious to the shopkeeper's requirements and desires, and in order to present these authoritatively we approached Mr. H. Gordon Selfridge, whose fine building in Oxford Street is certainly an excellent example of the way to treat the shop-front. Mr. Selfridge says, in a letter to us:—

"With the writers of the articles on London shop-fronts in your issues for April 17th and May 8th I do not quite agree. In one the Piccadilly Hotel building in Regent's Quadrant is designated as a 'grand piece of street architecture,' but with this description I must be permitted to differ. To me the design always seems to be an effort to do something large on original lines; but discovering originality in architecture in the twentieth century is very much like discovering originality in mathematics. I think we shall wait a long time before either façade is reproduced elsewhere, for, in my opinion, the building in no way improves London's none too impressive street architecture.

"On the other hand, I am one who believes that dignified architecture aids very much that business which it is to house. I differ from the writer of the letter published in your issue of May 8th, inasmuch as I feel that the entire abandonment of all attempts at fine architecture simply to provide a showcase from which the owner of the shop can sell a few more goods is most undesirable.

"It would be well to study the question from a broader point of view. What are the most pleasing and satisfactory results obtained in France, America, Germany? No good building rests upon what appears to be a showcase. Every well-designed edifice must have *apparent* means of support, evidently strong enough to sustain the superstructure. A building should, therefore, have piers which are not hidden by mirrors nor by decorations. The best buildings in the countries mentioned, whether used for little shops or large stores, are all supported from the ground by columns and piers evidently strong enough to carry the weight.

"While decrying the Quadrant design as, in my opinion, extremely unsuccessful, I earnestly advocate a street architecture which shall be fine, stately, and dignified. I urge that commerce and architecture shall be twin brothers, or partners in the scheme rather than enemies, and that all

sense of what is good in one shall not be sacrificed to secure what may seem, for the moment, to win a little better result in the other.

"The show-window is considered in London, more than anywhere else in the world, as of prime necessity to the shopkeeper. Personally, I do not agree with this position, and if I may refer to our own Store, I would say that the show-windows are important, but by no manner of means the whole thing. We could abandon our windows and do probably four-fifths as much business, simply because we insist that the departments themselves shall be the chief attraction, rather than the windows.

"The man who pays the rent must have something to say as to the building itself, otherwise he may refrain from occupying the same, but I hope that, while he is making his requirements known, he will feel that real architectural excellence supplies an asset to his business, and gives it, in addition, a dignity and character which a simple showcase-of-a-shop cannot possess."

We are very glad to publish the above expression of opinion. Mr. Selfridge may differ from some of our views of the merits of Mr. Norman Shaw's design for the rebuilding of Regent Street Quadrant, but it will be noticed that he is in complete accord with us in the contention that it is impossible to secure a satisfactory architectural result when every inch of available space is demanded for the shop window and when all supports for the superstructure are persistently hidden or disguised.

A Cardiff Shop-Front.

In connection with this design by Messrs. Pollard and Co., published below, the following particulars are supplied: "It is considered that in this scheme the architect's objection, in a general way, to a shopfitters' design is overcome. The pilasters are reasonably bold and the four columns at the entrance look substantial enough to support the superstructure; while, of course, the bases and capitals of the columns provide an opportunity for a certain amount of architectural detail. But although the supporting columns are such a prominent feature in this shop-front, they do not take away any space from the window—in fact, by the ingenious manner in which the glass has been carried round, the window is very much enlarged. No space has been sacrificed for these architectural embellishments, which is satisfactory from the commercial point of view. Hence it is considered that this design is a reasonable attempt at a compromise between the two opinions."

OUR PLATE.

Stanley St. Peter's, Wakefield.

The Church of Stanley St. Peter, Wakefield, was one of the churches erected to commemorate the Peninsular War and the Battle of Waterloo. It was carried out in the "Perpendicular" manner of those days, but with stone windows, not cast-iron, as commonly employed then. It originally consisted of one vast nave without columns under a single roof, but the acoustics were so impossible that changes had to be made. In the last quarter of the nineteenth century stone arcades were introduced, with false wood roofs underlying the weather roof. A year ago the church caught fire in a gale of wind and was entirely gutted, the external walls only being left standing. A new interior is now in course of erection, which includes a chancel. Messrs. Willcock and Co., of Wolverhampton, are the contractors. The architect is Mr. W. D. Caröe, F.R.I.B.A., F.S.A., of Westminster, whose drawing (reproduced as the Centre Plate in this issue) is exhibited at this year's Academy.

THE LONDON BUILDING TRADE
DISPUTE SETTLED.

The Amalgamated Society of Carpenters and Joiners has decided by a ballot vote to accept concessions offered by the London building trade employers, and as substantial concessions are also offered to the builders' labourers and other unions involved the strike notices which had been tendered will be withdrawn. It is understood that, instead of the immediate increase of 1½d. an hour demanded by the men, the employers offered to the carpenters and joiners an increase of ½d. an hour in September, with a further ½d. an hour next March, the present hours to remain unchanged.

R.I.B.A. DESIGNS FOR FINAL
EXAMINATION.

The Board of Architectural Education of the Royal Institute of British Architects announce the following additions to the list (see our issue of May 29th, page 566) of students whose designs for the Final Examination have been approved:

Subject I. (b).—(A Terrace of Five Houses). Mr. E. H. Gibson.

Subject II. (b).—(A cloister with external entrance gateway or tower to a collegiate building). Mr. E. H. Gibson and Mr. Wm. Voelkel.

DESIGN FOR A SHOP-FRONT AT CARDIFF, BY POLLARD AND CO.

NEW BOOKS.

Some Technical Manuals.

Two handy little books that deal with different aspects of a similar subject come from Messrs. Cassell. In "Bevels and Cuts," Mr. Edward Hardy claims to have "succeeded in evolving a system whereby the artisan can find the angles in such a position that he can easily adjust his bevels to them, and whereby he can develop his lines on the piece of timber which it is desired to cut." The system is made plain in a series of 228 diagrams. The price of the book is 2s. net. "The Steel Square and Its Uses Simply Explained" is illustrated with 200 diagrams, and is issued at the same price by the same firm of publishers. It deals mainly with the setting out, by means of the steel square, of all forms of roofs, but there are also chapters on the application of the system to stair-casing, handrailing, and door-framing.—It is more pleasant than surprising to find the manual by Mr. Frederic Richard Farrow, F.R.I.B.A., on "Stresses and Strains; Their Calculation and that of their Resistances, by Formulæ and Graphic Methods" (Whittaker and Co., 2, White Hart Street, Paternoster Square, E.C.; price 5s. net) has reached a second edition. The book has been to some extent remodelled. The examples have been associated with the particular branches of the subject to which they refer, instead of being collected in an appendix, additional matter has been included, and the calculations have been carefully checked throughout. The author, who, it will be remembered, was formerly Lecturer on Construction at the Architectural Association and

sometime Lecturer on Architecture at Liverpool University, has been careful to avoid the assumption of a greater familiarity with mathematical work than the average architectural student possesses. Tables of the strength of materials and other data are usefully included.—The latest addition to the excellent series of "Installation Manuals" which are being issued by Messrs. Constable and Co., Ltd., 10, Orange Street, Leicester Square, W.C., is an eighty-eight-page book, with rounded corners, that it may be the better accommodated in the pocket, on "Testing, Fault Localisation, and General Hints for Wiremen," by Mr. J. Wright. This is essentially a practical work and therefore avoids unnecessary theoretical disquisition. The operator is simply told what to do, without troubling him to master the abstractions that govern the action. There is, however, sufficient theory to enable the wireman to take an intelligent interest in his work.

The Mechanics of Building Construction.

The young architect, fascinated by the artistic side of his profession, too often neglects such studies as imply less prettiness and more fag. The mechanics of building construction, for instance, are seldom attacked with any high degree of enthusiasm, and the half-heartedness—not to say the whole-hearted aversion—with which this department of professional education is commonly approached is responsible for much incompetency. Distaste for the subject is more often intensified than corrected by the "base mechanical" way in which it is taught in classrooms and set forth in text-books. The author of the text-book under notice adds to uncommon skill as a teacher and lec-

turer a rare gift of clear exposition as a writer and draughtsman; nor is his knowledge of the subject merely academically derived. It is largely drawn from extensive practical experience. He is, in short, in every way highly qualified to afford competent guidance in a subject which, as he is able to expound it, seems by no means so abstruse as many timid souls imagine it to be. This book should therefore prove to be of real value to the student. Principles are explained in popular language, and afterwards their operation in or application to practical issues is illustrated both verbally and graphically.

The Mechanics of Building Construction. By Henry Adams, M.Inst.C.E., M.E.A., etc. With 590 diagrams. Pp. xii. + 240, 6 ins. by 9 ins., 6s. net. London: Longmans, Green & Co., 39, Paternoster Row, E.C.

KING EDWARD VI. SCHOOL FOR
GIRLS, BIRMINGHAM.

This school has recently been erected at Handsworth, Birmingham. Accommodation is provided for 475 girls. The assembly room measures 100 ft. by 44 ft.; beneath it are cloak room and drying room. At the south end of the building on the ground floor are the mistresses' rooms and the library, above which are the science rooms. At the other end is placed the caretaker's house, and the cookery classroom and dining-room, with the art rooms over. In the basement there is a gymnasium, also the play room, 120 ft. by 22 ft., opening direct on to the playground.

The architects of the school were Messrs. J. A. Chatwin and Son, of Birmingham, and the contractors Messrs. Collins and Godfrey, of Tewkesbury.

KING EDWARD VI. SCHOOL FOR GIRLS, HANDSWORTH, BIRMINGHAM: GROUND-FLOOR PLAN.
J. A. CHATWIN AND SON, ARCHITECTS.

AVIATION AND THE STRUCTURES OF THE FUTURE.*

BY HORACE CUBITT, A.R.I.B.A., P.A.S.I.

That the ultimate developments of Aviation must profoundly modify social life as well as international relationships and must affect building design and construction and the aspect of towns, is no longer merely a subject for weak jocularity and strong fiction, but for rational conjecture. Mr. Cubitt's paper represents a serious attempt to assemble and consider the practical factors of some of the problems that seem likely to arise.

ALTHOUGH a treatment of the subject-matter of this paper may appear to be but drawing a bow at a venture, yet upon analysis some conclusions result which may not be very far from the mark. A necessary preliminary to theorising on the aviation structures of the future is a consideration of the structures of the present. These, of course, are met with at every aviation ground, and consist of the workshops in which the aeroplanes are constructed and repaired, and the "hangars," or, in plain English, the sheds in which they are housed. To call a spade a spade is an English characteristic, and I see no reason why we should not call a shed a shed, and have done with it.

These buildings—workshops and aeroplane-sheds—as at present constructed, seem to be of a somewhat temporary character, the enclosures being of wood studding covered either with boarding or corrugated iron, and the roofs being light corrugated iron structures. This is only natural. In the early stages of any industry it is bad policy to erect buildings of too permanent a character, as it is very probable that a short experience will show that considerable alterations in planning and arrangement are required. But in course of time, when the twin industries of aeroplane construction and aerial transit are established as large factors in our national industrial programme, buildings of this slight construction will not suffice. When, in any industry, standard types of buildings have been evolved, it is bad economy in the long run to have resort merely to the semi-permanent forms of construction. Corrugated iron in our climate must be painted every year or so, otherwise the galvanising wears off and the material rusts through. The cost of maintenance is thus very heavy, and even if the material is well painted a life of more than thirty years is hardly to be expected. These remarks do not apply in quite the same degree to buildings with boarded enclosures, but there is the risk of fire to be considered, and in consequence this method of construction is prohibited by practically all local by-laws, except in situations remote from other buildings. All things considered, there seems no reason to suppose but that, when our knowledge of the requirements has been evolved from experience, aviation buildings will be as permanent in construction as those now erected in connection with the motor-car industry.

Forms of Construction.

When consideration is given to the form which this permanent construction will take; it is, however, a question whether plain brickwork will hold its own, or whether it will have to give place to one of the more modern forms of construction. As regards the aviation workshops, these, in common with new workshops of other kinds, may very probably be constructed

of a steel skeleton filled in with brickwork, or of that new combination of materials, reinforced concrete. Aeroplane-sheds, necessarily being, it is presumed, one-storey buildings of moderate height, will hardly lend themselves to steel-frame construction, but it would appear that reinforced concrete is particularly suitable for structures of this character. Experience in connection with the new General Post Office and elsewhere has shown that reinforced concrete is particularly suitable for buildings requiring large areas of unencumbered floor-space. Therefore it may be assumed that it will in due course be largely adopted for the construction of aeroplane-sheds, particularly if it is possible, as I believe now to be the case, to form watertight roofs of this material without asphalt or any other kind of covering.

One special constructional point in the design of aeroplane-sheds, whether buildings of the present size or those of the much greater proportions which we may expect to see in the future, appears to be the doors or shutters to close the necessarily large main openings. At the London Aerodrome the constructors of the various aeroplane-sheds will be seen to have exercised considerable ingenuity in the design of the wooden doors. It is evident that if the ordinary practice of making two folding doors to the main opening of a structure were adopted in the case of an aeroplane-shed, such doors would, on account of the great size of the opening, be most unwieldy, and the task of manipulating them in a gale of wind would be positively dangerous. Hence the need for doors or shutters which can be folded into several sections. While such a contrivance as that of having wooden shutters with vertical pivots sliding in grooved iron bars at the top and bottom of the opening may be efficient enough to warrant its occasional adoption in permanent buildings, it seems probable that, in the best class of work, steel rolling shutters, similar to those adopted in tramcar sheds, will be employed. Such shutters need not be in large widths, and would thus cause no difficulty in operation, while the advantage of having the shutters entirely out of the way when not in use is very evident.

A further important constructional point which does not occur in modern aeroplane sheds, but may be anticipated in future constructions, is the obtaining of large floor spaces with the absolute minimum of columns or stanchions. At present the aeroplanes in use are comparatively small—that is, compared with those we may expect in the future—and it is not, I believe, customary to put a number of aeroplanes in one shed. But, in due course, when an enterprise with such a title as the London Aerobus Company is in full swing, each building at the company's depôts will doubtless be constructed to contain a considerable number of aerobuses, and with these vehicles exceeding by many times the size of a modern biplane it will be necessary to keep the floor space almost entirely free from columns. To effect this

with due regard to economy will not be easy, but probably by a skilful use of reinforced concrete the problem will be satisfactorily solved.

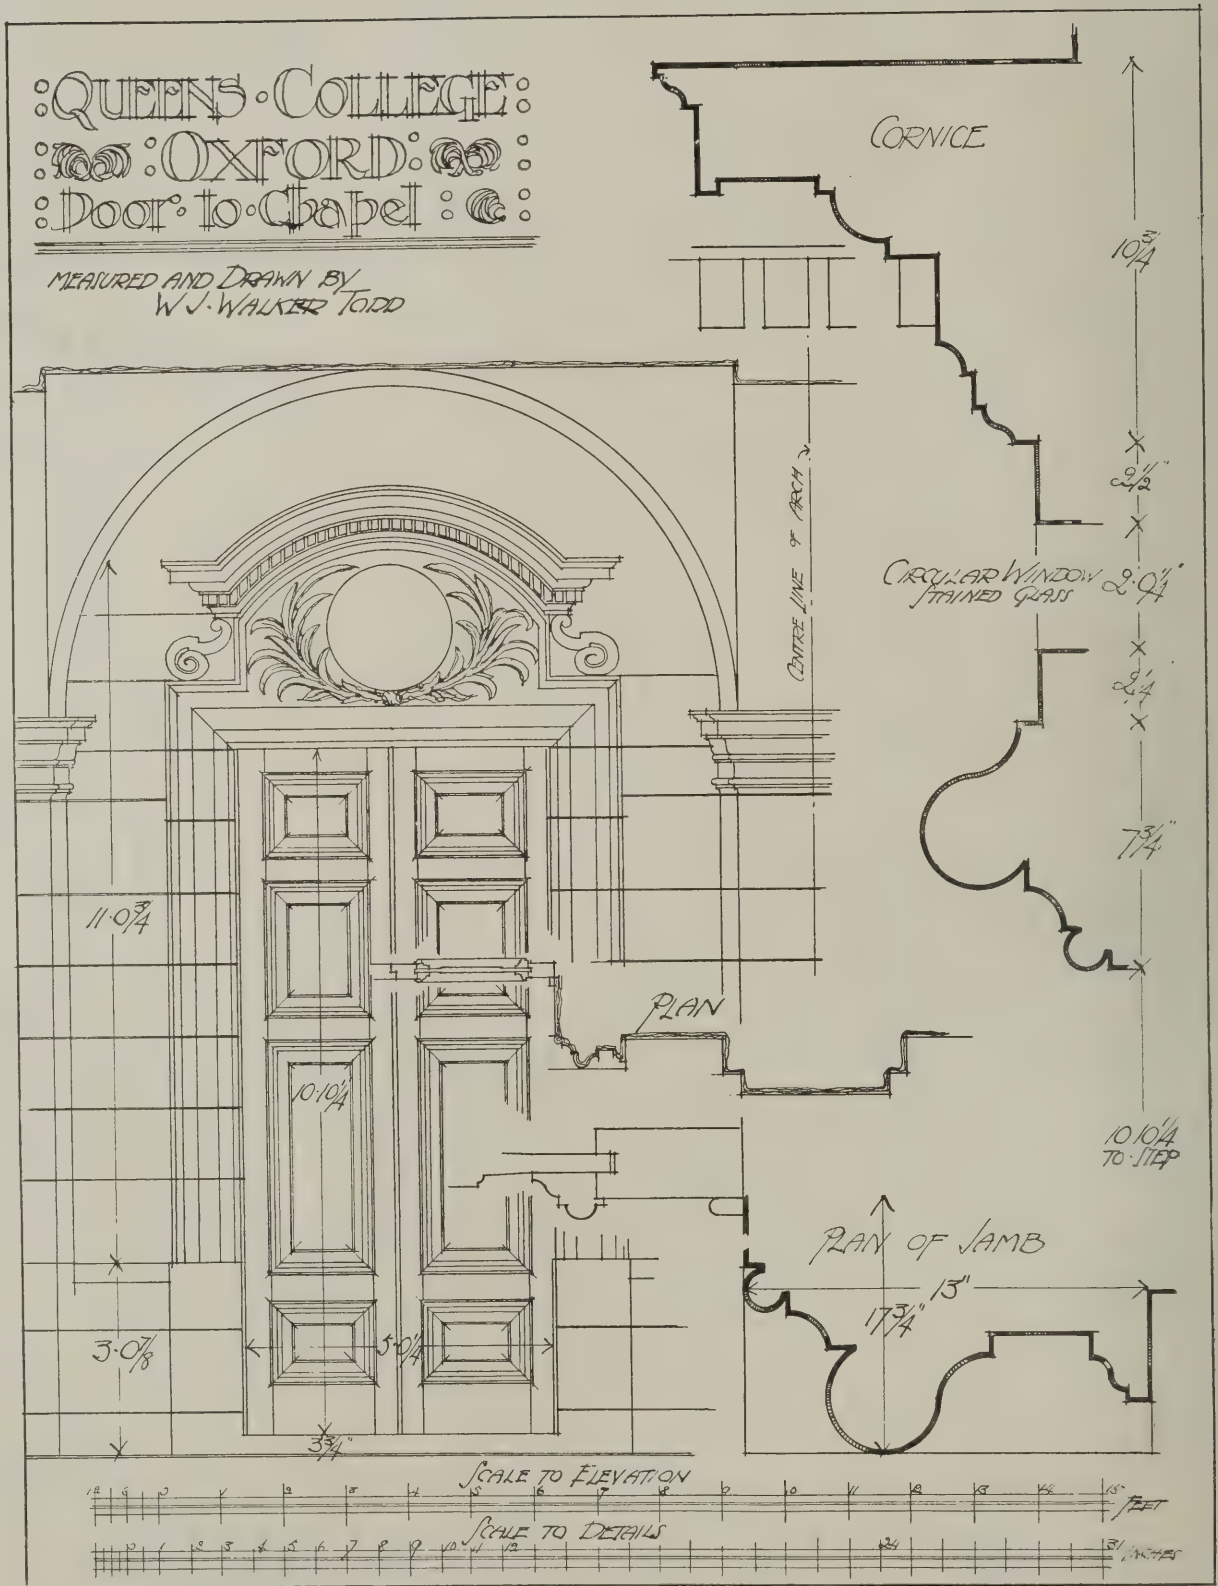

Thus far the structures considered have been those for important aeroplane enterprises. But, with the development of the science of flying, it is to be anticipated that before very long venturous spirits will be seized with the desire of discarding their motor-cars for aeroplanes, and an aeroplane shed will be a necessary complement to the outbuildings of a well-equipped house. The only special question which appears to arise in connection with such a building is the provision of a sufficient space for starting in front of the shed, it being an obviously difficult matter to "take wing" in the middle of a street of ordinary width, should such be allowed, as it probably will not be, by the responsible authority.

Town Landing Stages.

The subject of the structures to be erected as workshops for the manufacture of and as sheds for the housing of aeroplanes makes no great demands on the imagination. Structures of this kind already exist as a guide, and, in any case, the uses to which the buildings are to be put are not such as to necessitate any striking departures in construction. When the landing stages to be erected in large towns are considered, a more difficult case for speculation occurs. That such landing-stages will be necessary is almost self-evident. As soon as the risk associated with aeroplane flights has been reduced to a reasonable minimum, the present prohibition of flying over towns will be removed, or at any rate modified so as to be made applicable only to the central portions. Since town arrival and departure stations will require to be formed in populous districts where land is of considerable value, it will be a financial impossibility to provide open spaces at ground level of sufficient area to enable aeroplanes to descend and ascend without running the risk of coming into contact with the adjoining buildings. Hence the necessity for landing stages a little above the level of the buildings.

When I came to give a little direct attention to the subject of the design and construction of these landing stages for aeroplanes, I found upon self-analysis that such impressions as I then possessed had been formed by the perusal of a few works of authors of "futurist" tendencies, who, in writing of the wonders of a coming century, had given free rein to their imagination, regardless of the result—so long as it was sufficiently extraordinary. Landing stages, as thus described, were to be gaunt steel structures with legs like small Eiffel towers, dominating the country for miles around and making our ordinary buildings look mere pigmies beside them. There is no reason, however, to think that we are coming to this. In the first place, we are not likely to get uncased steel structures, standing in the midst of ordinary buildings. Local authorities would hardly allow them, because of the risk to adjoining buildings by their collapse in the event of a fire. Also we are not in ordinary cases, I think, going to have stages consisting merely of legs and a platform like a derrick. If, as seems certain, tall landing stages are to be erected in districts where land is very valuable, it will obviously be desirable to utilise the space below the landing stage—i.e., to erect ordinary buildings upon it. But if the site is cleared, and the buildings and the landing stage are to be erected at the same time, the question will at once arise, "Why not

* Extracts from a paper presented at a meeting of the Institution of Municipal Engineers on June 12th.

For particulars, see p. 636.

form them as one structure? If this is done, it will be obviously a waste of space to provide separate legs for the landing stage, as such stage can be easily supported on the walls or other enclosures of the building. Thus, prosaic as it may seem, the aeroplane landing stage of the future will probably be nothing more than a large and lofty building with a flat roof, on which and from which the aeroplanes will alight and depart. Lifts will, of course, be provided from the landing stage to the street level. The necessary waiting-rooms, etc., in connection with the aviation service will be placed in the top storey, and the lower storeys let as offices or for trade purposes.

It may be asked, How big are such aviation buildings likely to be? With aeroplanes of present-day size probably a landing stage 80 ft. to 90 ft. in width and about 200 ft. long would suffice to provide both departure and arrival platforms side by side. But, with the machines increased very considerably in size so as to be able to carry a fair number of passengers, it would seem that an area of at least 200 ft. by 200 ft.—nearly that of the Selfridge building, Oxford Street—would be required. Then there is the question of height. The ordinary limit of height for London buildings is 80 ft. to the top of the parapet plus two storeys in the roof, which results in a height of, roughly, 100 ft. from the street level to the ridge of the roof. Having regard to the desirability of being above all roof eddies, it would seem that the landing stage level should be about 120 ft. or 130 ft. above the street. This may appear an excessive height in a position where the surrounding buildings are comparatively low, but, except in a case where the immediately adjacent ground and buildings are in the ownership, or by some other means are under the control, of the body erecting the landing stage, it will be a questionable policy to erect a stage of less than this height. For, if such is done, there will always be the risk of its utility being jeopardised by the erection of new buildings, or the reconstruction of existing ones, to the legal limit of height.

As regards the form of construction to be adopted, neither brickwork nor stonework is suitable, if economy is a consideration. Both steel and reinforced concrete possess great advantages over the older forms of construction in the case of the erection of lofty buildings. As to which of these two forms of construction—a properly encased steel frame or a scientifically designed arrangement of steel and concrete—is likely to be adopted, it is hard to say. Probably both forms will find their supporters. A great deal has lately been written in praise of reinforced concrete, but the advantages of a steel frame for a lofty structure must not on this account be overlooked.

Situation of Aviation Structures.

A treatment of the aviation structures of the future is hardly complete without some reference to the situations in which they are likely to be erected. Having regard to the great distances that aeroplanes are able to cover in a few minutes, it seems reasonable to suppose that the sheds for the storage of the machines will be erected in the extreme outer suburbs of our towns, where land can be purchased at very little above agricultural value. The workshops will doubtless adjoin the sheds, but, of course, there will need to be a workshop or two in the heart of a town, so that urgent repairs can be dealt with without delay. The landing stages in towns of ordinary size will doubtless be erected

in the centre of the inner commercial districts. It will then be possible for business men to come direct to their offices from country districts some twenty-five or thirty miles out in the short space of half an hour. In very large cities, in London especially, it is questionable whether the responsible authorities will not do well, for reasons of public safety and convenience, to reserve a small area in the extreme centre of the commercial districts within which flying is prohibited, the landing stages in such cases being erected at intervals along the boundary line enclosing such area. There is a good deal to be said for such a restriction.

As an illustration of what is likely to take place when—it may be twenty years, it will certainly not be fifty years—aeroplane transit is established as one of the

ordinary forms of locomotion, let London be considered. As regards the housing of the aeroplanes, the necessary buildings will probably be erected, for the most part, well outside the present county area. The land on the south of the Thames beyond Woolwich will probably be found to be especially suitable for the erection of aeroplane sheds and workshops, as it is cheap, and materials, machinery, etc., may be conveyed to it by water. The question of the situation of the landing stages in the inner districts of London is a very attractive one for speculative thought. If flying is to be allowed without restriction over the whole of London, the obvious position for the principal landing stages will be along the Oxford Street and Holborn route, from the Marble Arch to the Bank, and on to Aldgate, this being the backbone of business

DOOR TO CHAPEL, QUEEN'S COLLEGE, OXFORD.
NICHOLAS HAWKSMOOR, ARCHITECT.

London. The Strand route, from Piccadilly Circus to the Bank, being next in importance, would, of course, be similarly served. But it is very questionable whether the erection of landing stages in the very centre of London should be allowed. The thought of fleets of aeroplanes converging on a landing stage at the Bank hardly suggests security. The tangle of traffic at the ground level at this point is sufficiently bad without the introduction of a further tangle in the air, with aerial police on point duty emulating the City police below. The reservation of a comparatively small area in the centre of London for ordinary surface and underground transit would tend to prevent any congestion of aeroplane traffic, with its obvious great dangers, and probable injurious effect on the subjacent locality. Such an area might be bounded on the north by the Marylebone, Euston, and Pentonville Roads, on the west by a line following the ordinary omnibus route from Chapel Street *via* the Marble Arch and Hyde Park Corner to Victoria, and extended to Vauxhall Bridge. On the south the river would appear to constitute the natural boundary, and on the east a line could be arranged to extend from the City boundary adjoining the river, through Aldgate to the Angel, Islington. It will be seen that even with our present means of locomotion any part of central London can be reached in less than ten minutes from some point on this suggested boundary line. The extra time in transit which such a restriction would involve is therefore comparatively trifling, and the little inconvenience would be very greatly outweighed by the advantage of having this clear area reserved in the centre of the metropolis.

LEGAL.

Responsibilities of Architects.

Sheriff J. P. Grant has issued his decision in the action in which the late Robert J. Macbeth, architect, sued William Beard more, of Flichity, Nairnshire, for £290, being the balance of remuneration for professional services in connection with the alterations on Flichity House. His lordship finds in fact that pursuer, in the exercise of his supervision as architect, allowed freestone of a colour and in a position disconform to contract to be built into the work, but that otherwise he duly fulfilled his duties of supervision; and in law that his executrix is liable to the defender in damages, which defender had claimed, in respect of the said freestone being disconform to contract; assesses the sum over and above the sum sued for at £200, for which sum he decerns in favour of the defender, and finds no expenses due to or by either party.

In his note, Sheriff Grant says an architect has no power to sanction deviations from the contract in anything that matters without the sanction of his client, even to make a better job. Doubtless in practice an architect often does so, and trusts to his client's subsequent ratification of his experience and knowledge, but he does so at his own risk. In the present case the architect's specifications provided that all stones for the dressings must be sound, hard, durable white rock, of uniform colour, and entirely free from all blemishes, such as iron-stones, clay-pits, and pebbles. In the surveyor's schedule it was provided that the freestone should be of the best liver rock, and be laid on their natural or quarry bed. If the surveyor had added general conditions to the schedule of quantities, his lordship could

not see how the architect could avoid responsibility for them. There could be no question on the evidence that the contract for the mason work on the combined specification and schedule was not properly carried out. The stones were not of uniform white colour, and many of them were not placed on their natural or quarry bed, and to remedy these deviations by replacing these stones would take a large sum of money.

With regard to the carpenter work, he believed that doors and floor were apparently right when passed by the architect, and subsequent defects might have been remedied afterwards if timeously disclosed, but he could find no reference to any complaint as to the woodwork before defender's agent's letter to the pursuer when the pursuer was practically deprived of the opportunity of seeing that latent defects were made good, and on this branch of the case his verdict was for the pursuer. By the contract the defender was entitled to expect freestone of uniform colour that could be reasonably called white, and was equally entitled not to have any stone on cant, though on the evidence his lordship doubted whether the house was any the worse for this deviation from the contract. In assessing the damage, he allowed for what he thought it would cost to make good this deviation, and he thought the sum of £200, in addition to the balance of fees unpaid, was as much as could be reasonably claimed.

Architect's Fees for Abandoned Plans.

In the Court of Passage, Liverpool, Archibald Leitch sued Ewing and Co., Ltd., and John Alexander Wilson, biscuit manufacturer, of Liverpool, for £150 in respect of fees for services rendered in the capacity of consulting architect and engineer.

The case for plaintiff was that early last year Mr. Wilson, at that time a principal of Ewing and Co., requested Mr. Leitch to prepare plans for the reconstruction of the factory situated in Strand Street. The preliminary plans were approved by Mr. Wilson, and plaintiff got out the bills of quantities and specifications, which Mr. Wilson retained. In November Mr. Leitch observed that the old building was being demolished. He made inquiries from Mr. Wilson, who informed him that he had given the work to someone else, as the tenders in respect of plaintiff's plans were too high. Mr. Leitch now claimed half fees for an abandoned contract. For the defence it was contended that plaintiff had gone far further than he was requested or expected to go. All that Mr. Wilson desired was an approximate idea of the cost of the alterations he thought of making. His Lordship gave judgment for the plaintiff for £150, less £80 paid into court.

OBITUARY.

Mr. Sydney Smirke, F.R.I.B.A.

The death occurred on June 5th, at Richmond, Surrey, of Mr. Sydney Smirke, F.R.I.B.A. It is remarkable that his grandfather, father, and uncle were Royal Academicians. He became a Fellow of the Institute in 1888, and served on the Literature Standing Committee. He was a member of the Council of the Architects' Benevolent Society, retiring in March, 1909.

Mr. E. J. Milner Allen, A.R.I.B.A.

We regret to have to announce the death (from pneumonia after a few days' illness) of Mr. Edmund John Milner Allen, aged

fifty-two. After studying at the Royal Academy, where he was a Silver Medallist in 1880, Mr. Allen was elected an Associate of the Royal Institute of British Architects in 1882 (extra Silver Medallist, Soane Medallion, 1883), and commenced practice in 1884. In addition to numerous works executed, both alone and with the late Mr. Arthur B. Gibson, he was joint architect, with Mr. J. W. Simpson, for the Liverpool City Hosnital (south), the Victoria Institute, Worcester, the Glasgow Fine Art Galleries, Kelvingrove Park, and the Cartwright Memorial Hall, Bradford.

Mr. Robert Morham.

Mr. Robert Morham, formerly architect of the City of Edinburgh, who died recently at his residence, 13, Lauder Road, Edinburgh, was born in Edinburgh in 1839, and was a pupil of the late Mr. David Rhind. After three years spent in the office of the late Mr. David Bryce, he came to London, where he was associated for four years with the late Mr. W. E. Nessfield. In 1866 he returned to Edinburgh and became chief assistant to the late Mr. David Cousin, then City Architect. Mr. Morham was appointed City Architect in 1873, and held the office until his resignation in 1908. The old City Chambers were enlarged from his designs, and he was the architect for the Corporation's Hospital for Infectious Diseases. He did much work in connection with the reconstruction of the North Bridge, and designed the Waverley Market and the Central Fire Station.

Mr. Charles R. Wells.

The death took place last week at Newcastle of Mr. Charles R. Wells, a retired builder and contractor, who had reached the advanced age of eighty-two years. Mr. Wells was eminent on the bowling-green, and took part in the match with the Australians when they visited Newcastle in 1901.

Mr. Henry F. Williams.

Mr. Henry Joseph Williams, who died at Brislington on June 7th, had designed the Law Union and Rock Insurance Company's offices in Bristol, and several branches of Lloyds Bank, but had been chiefly occupied as a valuer, his knowledge as to the value of property in the city and district having marked him out for retention in many important arbitration and law cases. He was born in Bristol in 1842.

Mr. F. Hildrey.

The death has occurred, in his fifty-fifth year, of Mr. F. Hildrey, a partner in a well-known Sunderland firm of builders and contractors. For many years he had been associated with his brother in large building contracts in the town. Latterly he had devoted himself to developing the large Valebrooke estate, Sunderland.

DETAILS OLD AND NEW.—XLIV.

Chapel Door, Queen's College, Oxford.

Hawksmoor's best work is to be found at Queen's College, Oxford, and the chapel door is a representative example of it. The mouldings are good—especially the bold architrave—and the working-in of the circular light over the door is a clever piece of design. All is of stone. The chapel was built about 1714. Owing to the fact that the entrance is in the "tunnel" connecting the first and second quadrangles, it is impossible to take a photograph of this doorway other than at an extreme angle. With the drawing reproduced on page 634, however, all purposes are served.

CONCRETE AND STEEL SECTION.

(MONTHLY.)

The Craze for Speed.

Reinforced concrete construction has introduced into the building industry much more of orderliness and method and much more of scientific observation than it knew before. Precision is now becoming a craze, and there are those who fear that it may become a tyranny. It is in America that the symptoms of over-development are most common. There they seem to do everything in a hurry. They no longer speak with what was once their characteristic drawl, which has been superseded by breathless rapidity of staccato utterance. They have invented the quick lunch and the fascinating phrase, "To get rich quick." They have also current the beautiful saying, respecting the avoidance, by pedestrians, of high-speed motor-cars, "If you ain't quick you're dead." They have instituted quick divorce. They build quick ("quickly" being too slow a word for them), and they want to build quicker. To this end they are taking observation and publishing books.

Concrete Costs.

It may be remembered that, some time back, we reviewed a book, by Mr. Frank B. Gilbreth, on motion study as applied to the laying of bricks. The reviewer greatly admired the industry and thoroughness with which the author had made his observations and worked out his conclusions, but ventured to doubt whether human nature was tough enough or tame enough to stand it all. The same misgiving haunts us persistently as we glance through the elaborate book on "Concrete Costs: Tables and Recommendations for Estimating the Time and Cost of Labour Operations in Concrete Construction, and for Introducing Economical Methods of Management." The book is by Mr. Frederick W. Taylor and Mr. Sanford E. Thompson, and is published in New York by Messrs. John Wiley and Sons, and in London (price 21s. 1d. net) by Messrs. Chapman and Hall, Ltd. It will be rightly inferred from the title that the motion study element is subordinate to the main purpose of the book, which is "designed to meet the needs of the contractor, as well as of the engineer and architect," by "the treatment of unit times and costs of concrete construction from the standpoint of rough approximate estimates; of accurate detailed estimates; of economical layout of work; and of scientific management with task and bonus." The times and costs are based usually upon average conditions and average workmen, instead of on scientifically managed operation, "because at the time of the issue of this first edition the application of scientific management to construction work has but barely begun, and cannot furnish adequate material for extended study on that basis."

Divergent Conditions.

The costs are naturally worked out in dollars, and the unfamiliar currency at once places the British reader at some disadvantage, which, however, could be easily overcome by the simple expedient of using a table of equivalent values. But this is obviously a small matter compared with the almost insuperable difficulty of accurate readjust-

ment for the apparently irreconcilable differences between American and British conditions of labour, rates of wages, standards of living, national temperament, supply and quality of materials, business methods, professional training and practice, and other matters upon which wide divergency is possible and actual. But while any attempt to adopt in detail for use in this country the tabulated results of American practice would seem to be quite hopeless, there are many data that are interesting, if not exactly instructive, by reason of their regular or their varying inter-relationships or relative ratios. Even these may not always be safely assumed to be independent of special conditions; and, in fact, as the authors acknowledge, "from the standpoint of the contractor, it is unfortunate that no two jobs are exactly alike; and in most cases the difference in the conditions of apparently similar jobs is so great that the records of the time and cost of one job enable the estimator merely to make a good guess at the cost of the next."

"Unit Times."

The authors imagine that they have discovered a way out of this seeming impasse. They believe that, for obtaining the best knowledge of the time required for doing concrete-construction work, there is a better method than that of simply keeping records of the pay and of the time of gangs or workmen. It is claimed that "a far more accurate plan for estimating costs is the method adopted in this book of dividing each kind of work into a series of small elementary operations, and of then timing and recording each of these 'unit times,' and, finally, of adding together the proper series of unit times in figuring the cost of a new job. This method is new in the building trades, although it has been successfully practised for years in many large machine shops and in engineering and manufacturing establishments."

Study with a Stop-Watch.

Mr. Taylor, when foreman in a machine-shop, found that most of his many troubles with the men arose from the fact that neither he nor they knew how long a given job ought to take, "and then he studied with a stop-watch the time which a first-class man should take to make each of the elementary movements into which all kinds of work may be sub-divided. By adding together the proper series of these 'unit times,' the correct speed for doing any kind of work was obtained." Mr. Thompson, the joint author of the book, joined him in an effort to apply these principles to the building trade. Approximate costs of reinforced-concrete buildings are deduced in terms of cost per square foot of floor surface. The tables and curves cover a wide range of areas and types of buildings, and the values include all miscellaneous details, such as windows, stairs, lifts, etc., giving a general idea of the probable cost of a contemplated building, and also a means of comparing the cost of different designs.

Economising on Cement.

The proportioning of concrete is exhaustively considered, an entire chapter being devoted to it. For large jobs, it pays to make

thorough preliminary studies of the aggregates; the materials being carefully graded with the object of reducing the necessary cement to the minimum quantity; for "by adjusting the proportions of the aggregates instead of selecting them arbitrarily, a concrete of equal density, strength, and watertightness may be made almost always with the use of less cement." The voids in sand and broken stone may be determined simply by weighing the material, and then finding the percentage of moisture by weighing the moist sand, then drying it in an oven at a temperature of at least 212 degrees Fahr. until there is no further loss in weight. The dried sand is then weighed, and the loss in weight is expressed as a percentage of the total weight of the moist sand.

Handling Materials.

Almost every page of the book contains useful suggestions as to the more economical handling of material; and the general impression left on the mind is that while it would, for various reasons, be impracticable to go to the extremes of vigilance that make up what is necessarily a counsel of perfection, valuable guidance is afforded towards the quite attainable object of getting much nearer the mark than would be possible without a steady and systematic attempt towards economy in each and all of the formidable number of details on which slight loss or slight gain may be effected, according to the efficiency or the slackness of the management. For the American reader, the very numerous and most laboriously compiled tables will be of invaluable assistance. In this country they may be of but little direct utility. Here, what will be most highly esteemed is the patient and complete marshalling of the data of reinforced-concrete construction, the close scrutiny of each item, and the practical deduction that is evolved. It is in the right spirit of the watchful supervision that is essential to sound work in this particular field; and here it is hardly necessary to add the caution that, after all, strict economy is a much inferior consideration to a strict regard for absolute safety; and for that reason the practitioner will always be careful to avoid cutting things too fine. He will always provide a fair margin of safety. Ignorance may have made that margin much too wide—or, in some instances, too narrow; but on the whole it may be safely said that, in this country, reinforced-concrete construction is still attended by much unnecessary waste; and careful attention to the facts set forth in this book should help to reduce it very materially.

"Motion-Study" Again.

With regard to the question of time-saving and labour-saving through motion study, the present moment is rather inopportune for its calm consideration. The existing "labour unrest" excludes, for the moment, any attempt to throw into the arena what would be instantly pounced upon as an additional cause of irritation. If there is one thing more prominent than another among the "present discontents" of labour, it is the bitter antagonism of the men towards the

systematic extraction of the last ounce of energy that they are capable of yielding under American methods of "scientific" exploitation. They are moving heaven and earth with the object of establishing their claim to be regarded as men, not as machines; and if they are to be won over to superior methods, it will first be necessary to convince them that their humanity is properly recognised and respected, and that their claim to a share in the advantages of intensification will not be ignored. The rank and file of the concrete workers in this country are, on the whole, a skilful and dependable body of men; and any attempt to hustle them would immediately result in much more harm than good.

KNEE-BRACED ROOF TRUSSES.

Effect of Reactions upon Wind Stresses.

BY EWART S. ANDREWS, B.SC.ENG. (LOND.).

In designing roof-trusses for workshops, sheds, etc., it is very common to provide knee-bracing to give lateral strength against the wind. The calculated stresses in such a truss, however, depend upon the assumptions which are made with regard to the reactions, and it is the aim of this article to show how much is the variation for various methods of treating the reactions. We will take one example and find the wind stresses for the following assumption as to the reactions:—

- 1. Reactions act at junctions of knee-braces and columns.
- 2. Reactions act at half the distance between the junctions and the bases of the columns.
- 3. Reactions act at the bases of the columns.

FIG. 1.—LOADS AND DIAGRAMS FOR CASE I.

Case I.
This assumption is, according to the writer's experience, the usual one adopted in this country, each reaction being taken as parallel to the resultant wind force. Fig. 1 shows the roof truss and stress diagram for this case. The span is 40 ft. and the rise 10 ft.

FIG. 2.—LOADS AND STRESS DIAGRAM FOR CASE II.

Taking a wind pressure upon a vertical surface of 30 lb. per sq. ft. and considering the stresses per foot apart of the principals, we get from the usual wind-pressure tables:—
Wind pressure per square foot of rafter = $59 \times 30 = 17.7$ lb. . . Total wind force on rafter = $17.7 \times 22.36 = 400$ lb. nearly.

This is divided up as indicated in Fig. 1. On the side we have a wind pressure = $30 \times 5 = 150$ lb., which is divided up as shown.

These forces are then set out on the stress diagram $o\ 1\ 2\ 7$, as shown, and by joining $o\ 7$ we get the resultant wind load W .

This acts through the intersection of the rafter load of 400 lb. and the side load of 150 lb., and the resultant load is drawn parallel to $o\ 7$ to intersect the line joining the reaction points $Y\ Z$ at the point a_1 . The line $o\ 7$ is then divided at x , so that

$$\frac{ox}{x7} = \frac{a_1Z}{Ya_1}$$

This may be done by drawing $o\ z$ horizontally equal to a_1Z and $7\ y$ also horizontally equal to $Y a_1$ and joining across. Then $7\ x = R_z$ and $x o = R_v$.

The stress or reciprocal diagram is then drawn without difficulty as shown, and the results will be given in tabulated form later.

This method is not very accurate.

Case II.
The reactions in this case are taken as acting half-way between the junction of the knees and columns and their bases, this assumption being very nearly correct in the case where the bases of the columns are absolutely fixed in a vertical division.

Each reaction is taken as resisting equally the horizontal component of the resultant wind force.

The roof-truss and forces acting on it, together with the stress diagram, are shown in Fig. 2, the stress diagram in this case being drawn to half the scale adopted in the previous case in order to save space.

The wind force on the rafter is, as before, 400 lb.; on the side we have a wind force of $30 \times 11 = 330$ lb., which is divided up in proportion to the lengths as shown. Before we can proceed with the stress diagram in this case we must assume some additional bracing to take the bending stresses in the column. This additional bracing may be assumed to be of any form, and a suitable one is shown in dotted lines.

The wind forces are then set down on the stress diagram $o_8, 1_7$ as shown, and by joining o_7 we get the resultant wind force W , which, as before, acts at the intersection of the vertical and horizontal wind forces, and in this case intersects the line YZ in the point a_3 .

To get the reactions, we bisect the line o_7 at the point c_1 and draw through this line a vertical $b_1 d_1$ to the horizontal lines

through o and 7 ; $b_1 d_1$ is then divided at the point x , so that

$$\frac{b_1 x}{x d_1} = \frac{a_3 Z}{Y a_3}$$

and this may be done graphically as in the previous example.

Now join $7x, x o$, then

$$7x = R_z; x o = R_y.$$

Starting at the point 8 on the stress diagram we then draw a dotted line $8v$ parallel to $8V$ to meet the vertical through x in v and then draw vu horizontally to u to meet a line through the point I parallel to $I U$; then draw ua vertically and xa parallel to XA to give the point a and the stress diagram can then be completed in the usual manner without much difficulty.

As will be shown later, the stresses in

many of the bars in this will be very different from those obtained in Case I. As we indicated above, the absence of the bracing shown in dotted lines causes bending stresses in the columns.

This bending stress is greatest on the leeward side, and the maximum bending moment is equal to the horizontal component of the reaction R_z (i.e., $7 d_1$) multiplied by half the distance from the base of the column to the junction with the knee brace.

If the columns at each side are very securely bolted down, this treatment is much more accurate than that given in Case I.; if the fixing of the columns is not to be very strongly relied upon, then the more correct treatment is to take the conditions assumed in Case III.

THE ETON MEMORIAL: STEELWORK OF DOME.

THE DOME OF THE ETON
MEMORIAL.

The Eton Memorial was erected in 1906 in memory of the Old Etonians who fell in the Boer War. It comprises a great hall, a museum, and a library surmounted by a dome, the construction of which is shown by the accompanying illustrations. The library is an octagonal building, nearly

60 ft. in diameter, the dome being circular on plan and having a diameter of 44 ft. It is carried on stanchions clear within the walls, springing at 36 ft. above the ground and rising 31 ft., the crowning lantern adding a further 15 ft. to the height. The outer covering of the dome is of lead on boarding, the ceiling being of fibrous plaster attached to the lower chord. The steel framing is designed to fit both the

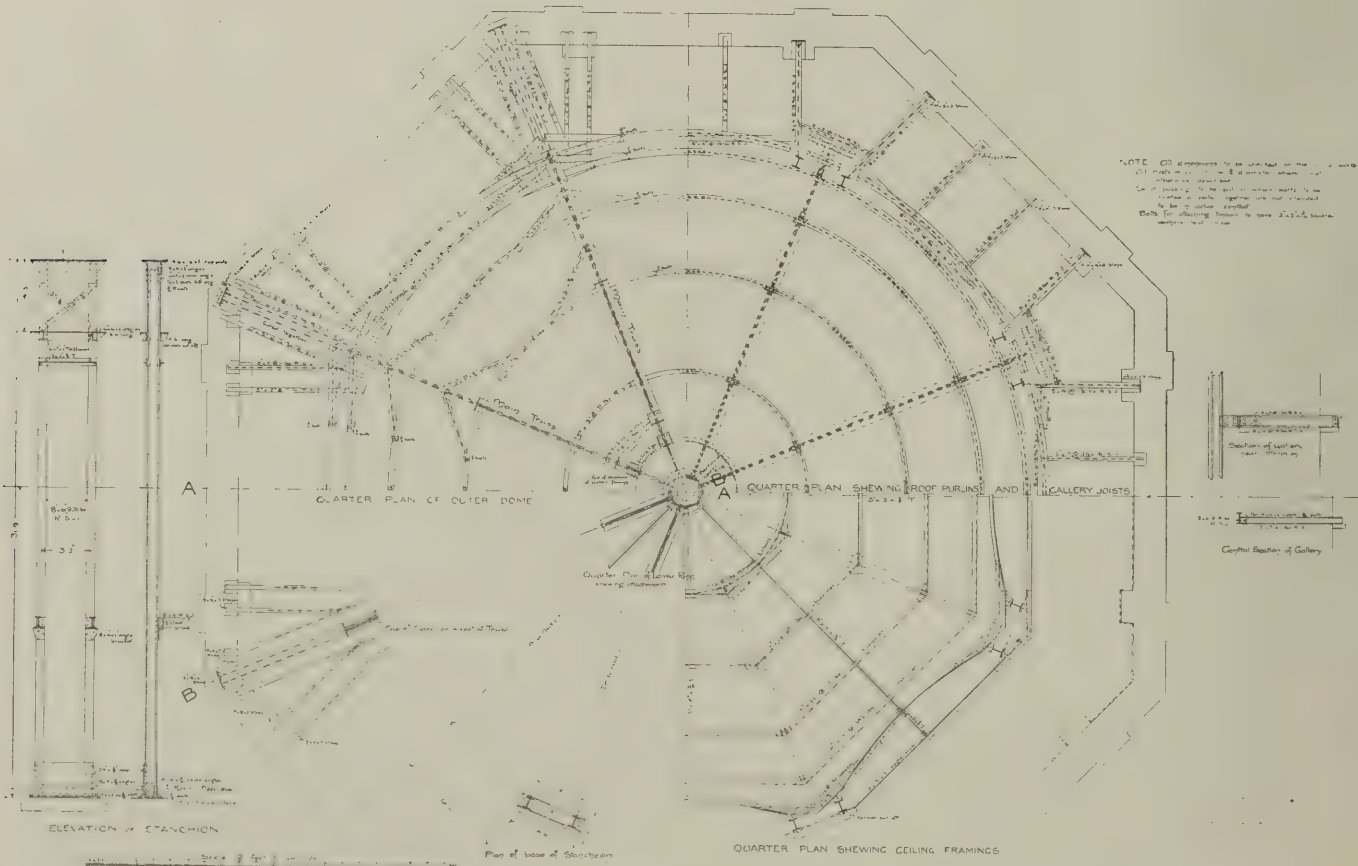

external contour and the ceiling of the library, which is also domed, but in a different form. An opening is provided in the centre for ventilation, and provision is made for attaching a pendant. The framing contains about sixty tons of steel, all of British manufacture, and it is calculated to exert no thrust on the walls.

The architects were Messrs. L. K. Hall and S. K. Greenslade, the consulting engineers being Messrs. Whitaker, Hall, and Owen. The steelwork was carried out by Messrs. Matthew T. Shaw and Co. The general contractors were Messrs. Henry Willcocks and Co., of Wolverhampton.

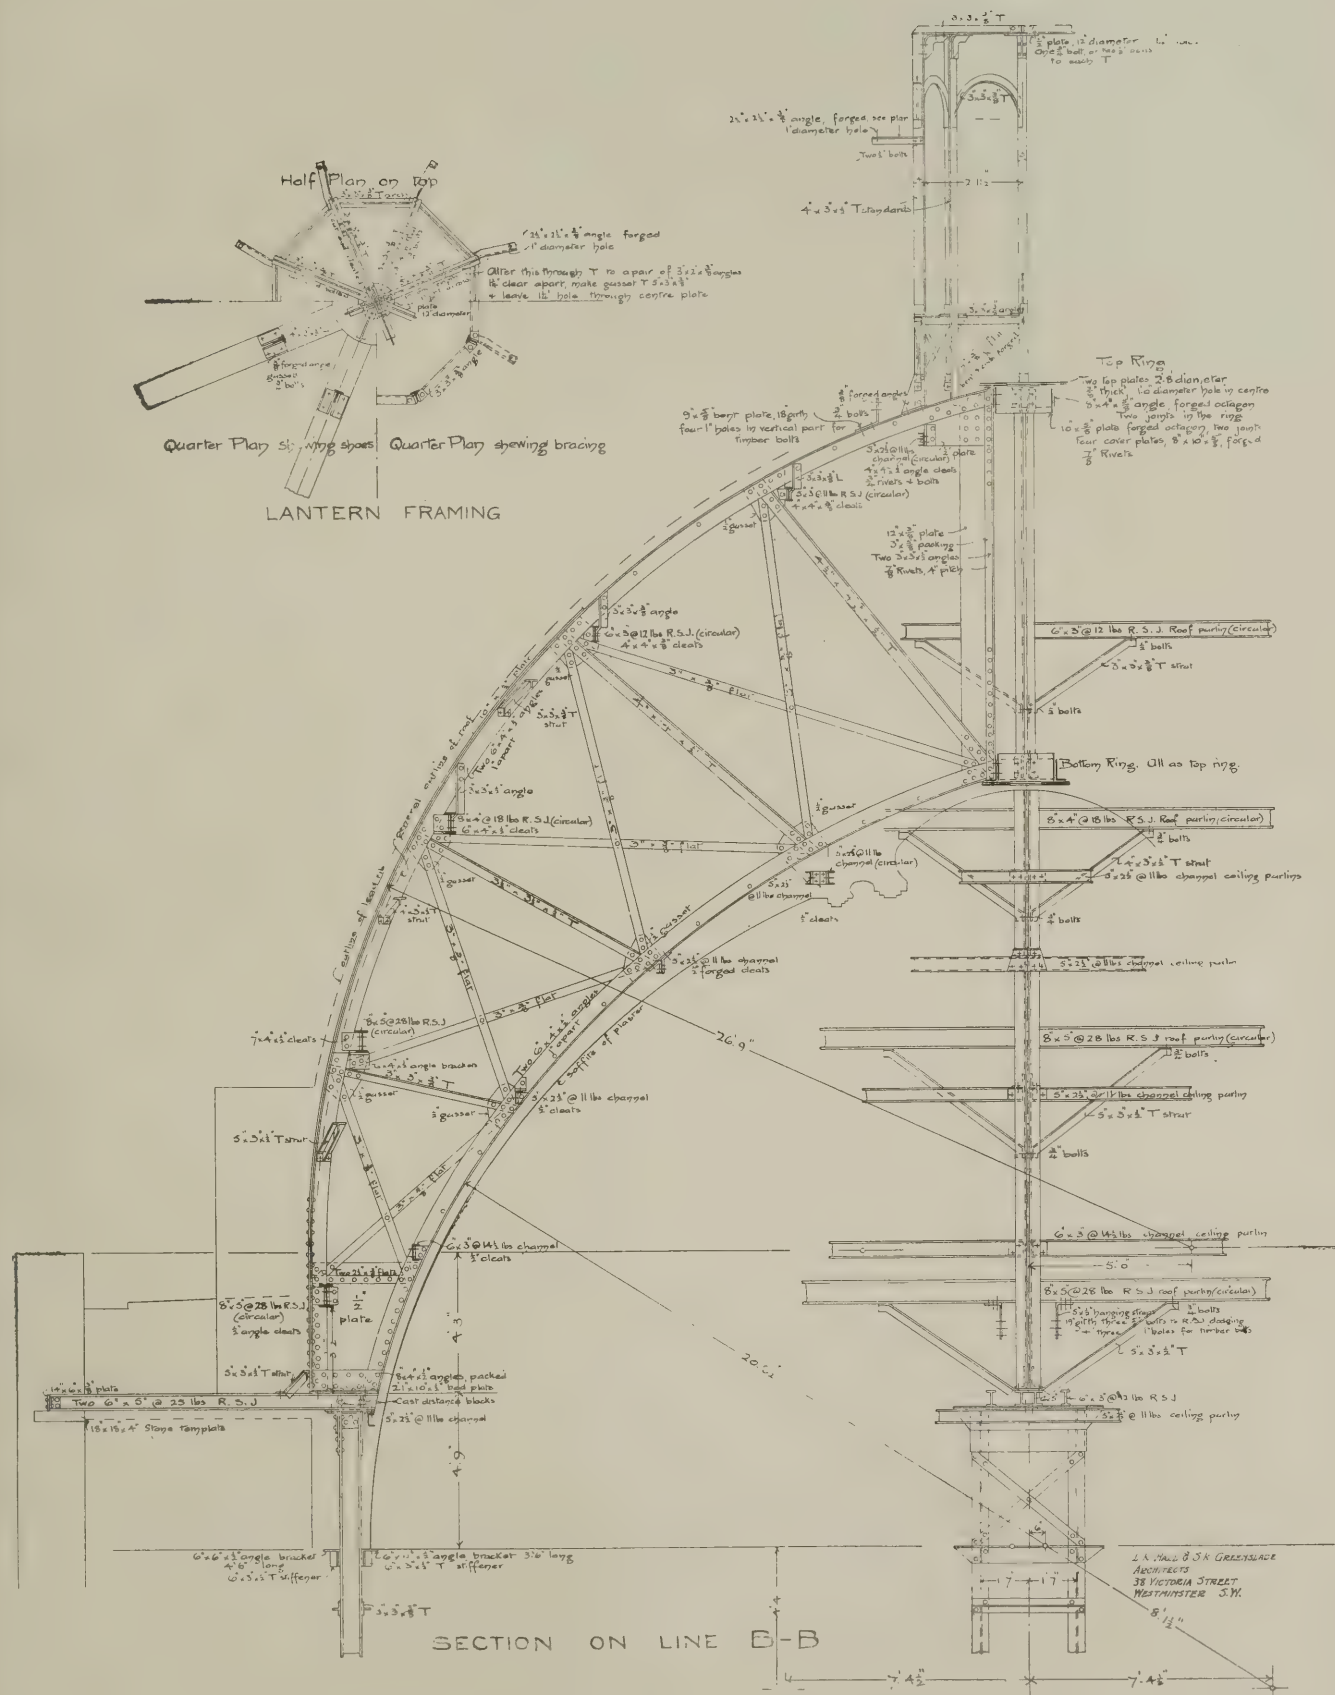

BY-LAW AS TO BUILDINGS OF STEEL
OR IRON FRAMEWORK.

The Local Government Board has provisionally approved the following by-law proposed to be made by the Chelmsford Town Council with respect to new buildings to be constructed with steel or iron framework:—

“From and after the date of the confirmation of this by-law every wall of a new public building or of a new building of the warehouse class which shall be constructed with steel or iron framework and in accordance with the following requirements:—(a) The framework shall be of sufficient strength to secure the due stability, and shall be properly put together; (b) The framework shall be filled in with bricks, stone, good cement concrete, or other hard and incombustible material properly and solidly put together, and of such thickness as shall be necessary to secure due stability to such filling;—shall be exempt from the operation of the by-laws numbered 10 to 34 in the series of by-laws with respect to new streets and buildings which was made by the mayor, aldermen, and burgesses of the Borough of Chelmsford.”

CONCRETE FOUNTAIN IN CENTRAL PARK, LOS ANGELES.

A CONCRETE FOUNTAIN.

That concrete lends itself with considerable kindness to artistic treatment only an extremist would deny. Any failure of æsthetic effect may be generally attributed to other causes than the unsuitability of the material; bad design, for instance, in the sense of imperfect adaptation to the idiosyncrasies of concrete. The material has a character that is all its own; and it is very doubtful whether as yet there is an effective understanding of its behaviour in the working or of the resultant effects. The conservatism of artists, and their reluctance to accept a new medium, has cast an undeserved stigma on all forms of concrete,

and has prevented that earnest and thorough study which might result in the full revelation of its possibilities and its limitations—of the treatment to which it sympathetically responds, and of that against which it sullenly rebels. What can be done with it, and what should not be attempted, have yet to be definitively discovered. Tentative essays in this direction usually err through the very natural adoption of methods that are more appropriate to other materials. In the illustrations, for instance, here shown of the concrete fountain in Central Park, Los Angeles, the pedestal and basin differ but little in form from what might have been expected if

they had been sculptured in stone. This is quite the normal course. It is invariably the case that the newer medium is at first treated in close imitation of the older, and the right method is only discovered through a necessarily slow process of trial and error—something in the nature of evolutionary development. With regard to the question of durability, the sculptor, loving to imagine that his work will endure for many generations, distrusts a material that is more plastic and tractable than bronze or stone; than which, nevertheless, it is probably more permanent, and is certainly more easily kept in repair. A concrete fountain erected in Wade Park, Cleveland, Ohio, some thirty years ago is reported as being still in good condition; and it will not be denied that the cement of to-day, being of vastly superior manufacture, gives both greater facilities in the working and more assured promise of durability. There can be no doubt that in this country, as in America, the love of statuary is rapidly increasing commensurately with the demand for parks and open spaces. Where the cost of bronze and stone is prohibitive, cement statuary will often be adopted; and it may be anticipated that artists will not disdain to work in it as they come to realise that it is not really a mean medium when its character is really understood, and when, consequently, it can be treated with sympathetic candour, not as imitation stone, but as a separate entity having its own distinctive characteristics and pretending to be nothing more nor less than what it is—less noble and costly, perhaps, than bronze or stone, but nevertheless deserving to be regarded as something better than a sham.

CONCRETE FOUNTAIN, LOS ANGELES.

REINFORCED CONCRETE COAL STORE AND GANTRY, ROCHDALE GASWORKS.

The Rochdale Corporation having decided to erect an installation of vertical retorts, the question arose as to the most economical method of conveying the coal to them. There is no railway connection with these works, and all the coal would have to be carted from the railway company's sidings. A high-level entrance and gantry to the works already existed from the main road to the existing retorts, and the corporation decided to construct a similar one to supply the new settings of retorts, but in this instance they adopted reinforced concrete in preference to masonry or brickwork. The accompanying illustrations show the work. It will be noticed on section D A B (Fig 1) that there is a difference in level of 32 ft. between the gasworks yard and the main road, which gives that depth of room in the coal store.

The work consists of a coal store averaging 106 ft. by 48 ft. by 32 ft. high, and a gantry forming a high-level roadway between the top of the store and the existing high-level roadway mentioned above. The length of the new roadway is 175 ft., and the width of decking is 40 ft. The general arrangement is shown in Fig. 1.

The floor of the coal store consists of a reinforced concrete slab 6 in. thick (which forms a raft to distribute the loads from columns), with 16 in. by 12 in. secondary beams, 10 ft. span, spaced at 5 ft. 6 in. centres, and 26 in. by 14 in. main beams 16 ft. span, all reinforced with Kahn trussed bars and Kahn rib bars.

The vertical walls resisting the outward pressure from the coal vary from 6 in. thick at the bottom to 4 in. thick at the top. They are supported laterally by 14 in. by 8 in. horizontal beams of 10 ft. span, the reactions of which are transmitted to framed trusses 16 ft. deep composed of 12 in. by 8 in. struts, the ties varying from 12 in. by 8 in. to 9 in. by 6 in. at the top. All the members are reinforced with four Kahn rib bars and 3-16 in. diameter wire ties spaced 9 in. apart. The two vertical booms, which also act as columns supporting the floor over the store, are 12 in. square, reinforced similarly to the struts. The internal boom

FIG. 3.
GENERAL VIEW FROM BELOW.

FIG. 2.
PLAN SHOWING POSITIONS OF COLUMNS AND BUTTRESSES.

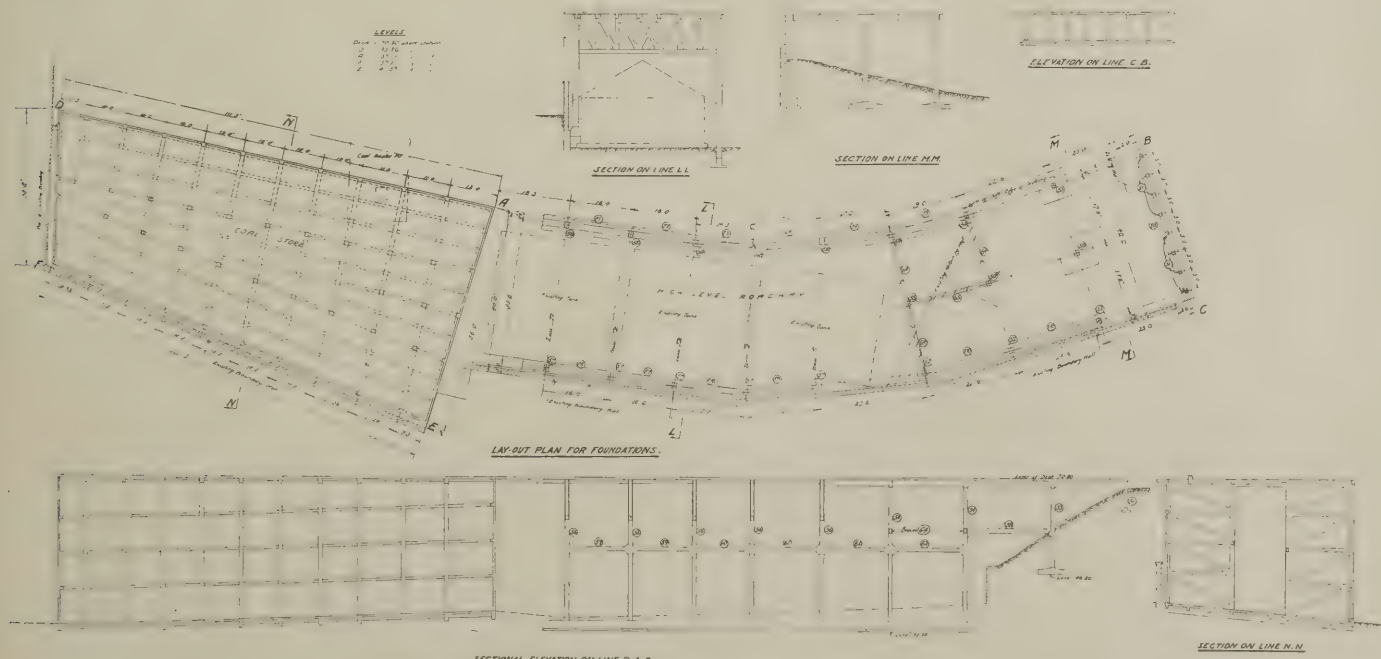

FIG. 1.
COAL STORE AND GANTRY, ROCHDALE GAS WORKS.

is stiffened by 12 in. by 8 in. horizontal braces splayed to the same at the junctions. It would have been more economical to have designed the main vertical members of the wall as beams tied at top and bottom and say at the half depth, but owing to the possibility of the coal being banked up on one side wall only it was decided to construct the sides as independent retaining walls. The construction described above is clearly illustrated in Figs. 2 and 3.

The floor over the coal store is constructed with a 6 in. decking slab supported on 14 in. by 9 in. secondary beams, spaced on an average of 5 ft. 6 in. centres

and carried on 20 in. by 12 in. main beams at 10 ft. centres and 16 ft. span. The depths of the beams in all cases include the thickness of the decking slab.

Openings 9 ft. by 5 ft. are formed in outside panels of the floor to allow the coal to be tipped from the carts into the store, a 12 in. by 12 in. concrete curb being provided to form a stop-block for the cart wheels.

The gantry connects the floor over the coal store with the existing high-level road, as described. For three bays from the high-level road it is supported on 16 in. by 12 in. outside columns, spaced 22 ft. apart, with one internal column

16 in. square, thus making the main beams, which are 28 in. by 14 in., about 18 ft. span.

The decking is 6 in. thick and the secondary beams are 24 in. by 12 in., spaced 5 ft. centres. Owing to the unsatisfactory nature of the ground, it was considered advisable to support the columns on continuous base beams in order to spread the load over as large an area as possible. A typical column base is shown in Fig. 4.

In the remaining portion of the gantry the centre column could not be constructed owing to the existing cast-iron tanks, which it was impossible to remove. Consequently the main beams had to span the

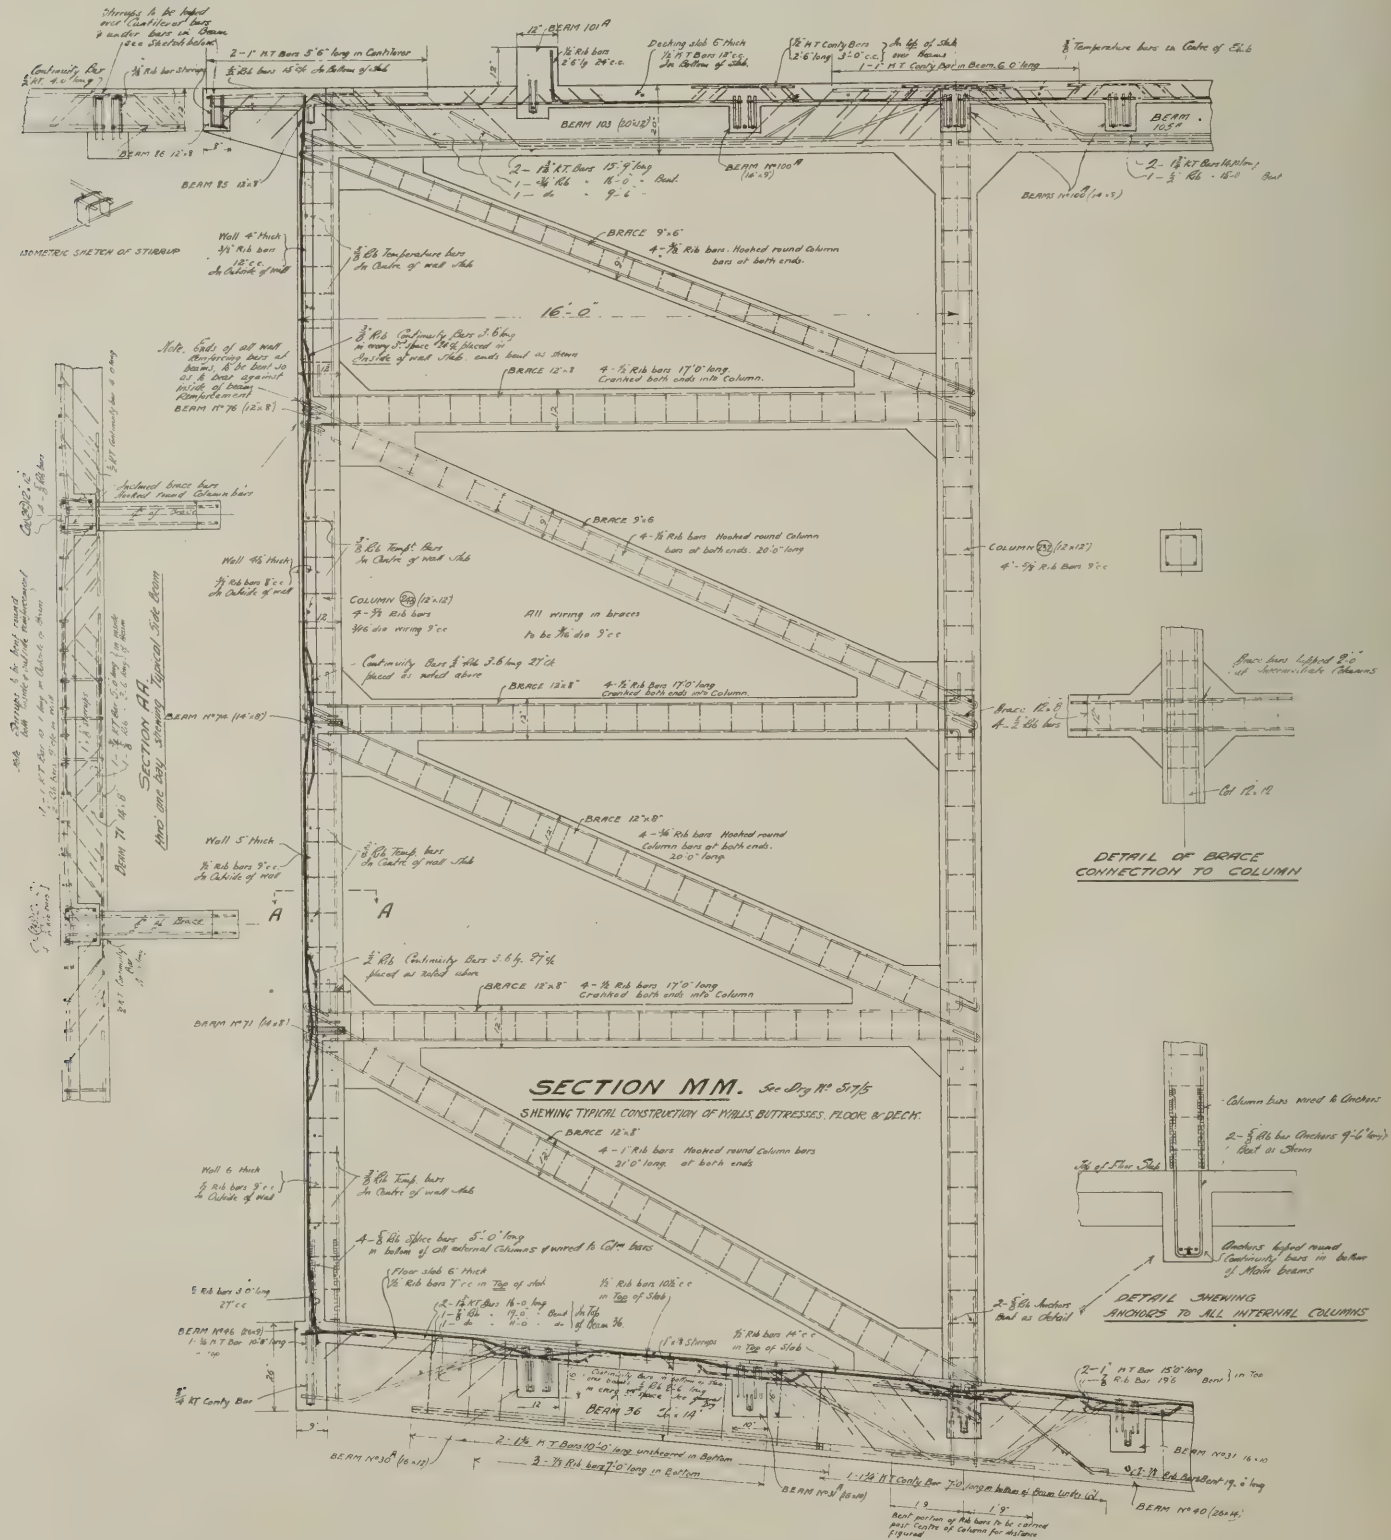

FIG. 4.

COAL STORE AND GANTRY, ROCHDALE GAS WORKS: SECTION SHOWING TYPICAL CONSTRUCTION OF WALLS, BUTTRESSES, FLOOR AND DECK.

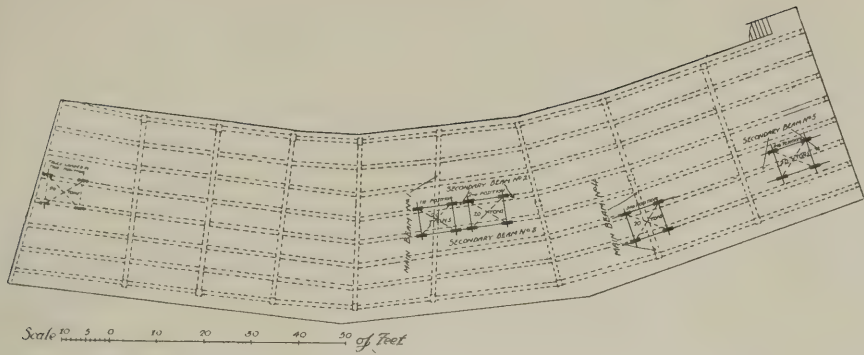

FIG. 7.—DIAGRAM SHOWING FOUR POSITIONS OF TEST LOAD.

whole width of the gantry between the outside columns. To reduce the dead weight of the construction as much as possible, the beams were designed as N-type girders 10 ft. deep, as headroom was not a governing factor. The bottom or tension boom is 12 in. by 12 in., the web struts and ties are 10 in. by 10 in., the compression boom is 16 in. by 12 in., and the slab for a width of 12 in. on each side of same is calculated as assisting the boom to resist the compressive forces. The whole of the reinforcement of these girders consists of Kahn rib bars, with 3-16 in. diameter wire ties spaced from 12 in. to 6 in. apart. Some of the bars in the tension boom had to be 50 ft. long in order to avoid welding or splicing.

The outline of one of these trusses is shown in Section LL, Fig. 1.

The great length of the construction necessitated provision for variations in temperature; this was provided by an expansion joint between the gantry and the coal store. Brackets were formed on the columns in the end wall of the store to take cross-beams supporting the secondary beams of the last bay of the gantry, two layers of oiled paper being placed on bracket before concreting the cross beams, which were cast so as to leave a space of 1/2 in. between the gantry and the coal store. A continuous asphalt dowel covered the top of the space to exclude dirt and sludge.

The parapet wall to the gantry was constructed in brickwork resting on the decking slab, which is cantilevered over the outside beams about 1 ft.

A slate roof supported on steel trusses was constructed over the coal store, and the surrounding walls were built of brickwork with openings for ventilation.

The gantry and floor over the store is paved with 6 in. granite setts laid on a 3-in. thick bedding material.

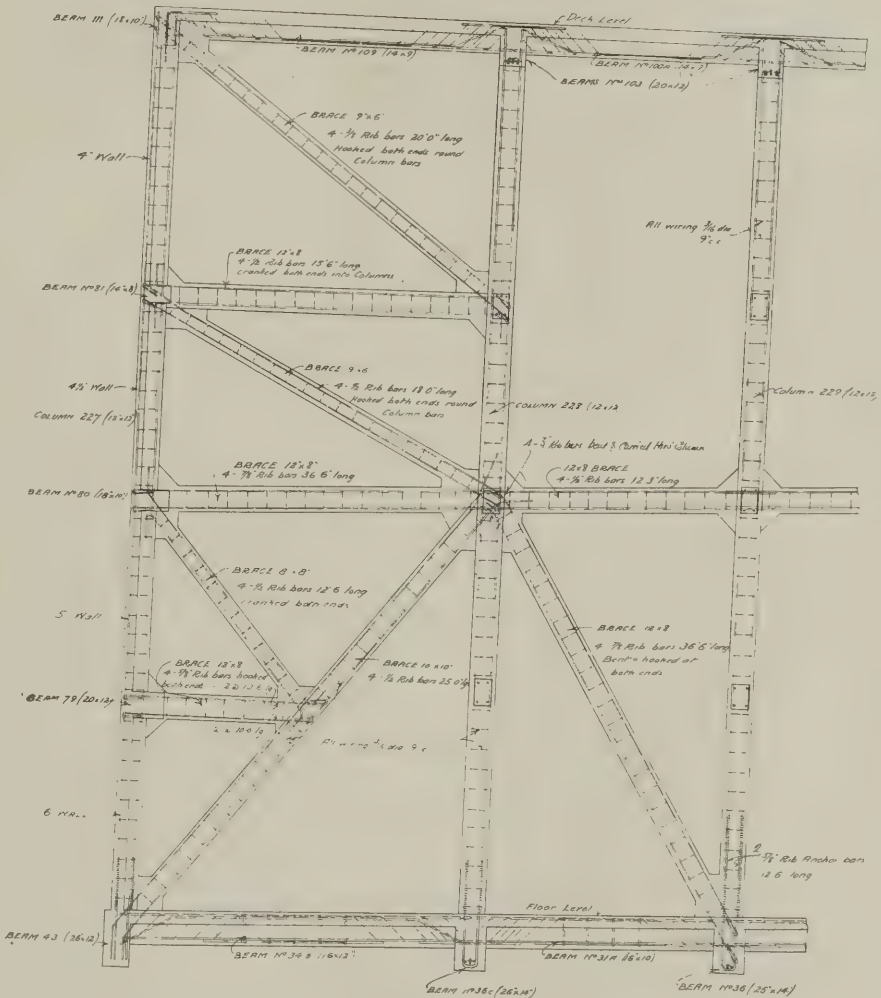

Description of Test.

On February 28th, 1912, the high-level roadway was subjected to the following test: A truck having a wheel base 7 ft. 8 in. long by 5 ft. 8 in. wide, the width of the wheel tyres being 9 in., was loaded to a weight of twenty tons in the position indicated on the extreme left of

the diagram. The test load was drawn across from left to right, the deflections at the four positions shown on the diagram being as follows:

- Main Beam No. 1 (first position of load) = 3/8 in.
- Secondary Beam No. 2 (second ditto) = 1/4 in.
- Secondary Beam No. 3 (ditto ditto) = 1/8 in.
- Main Beam No. 4 (third ditto) = 1/4 in.
- Secondary Beam No. 5 (fourth ditto) = 1/8 in.

The reinforced concrete work was carried out on the Kahn system from designs prepared by the Trussed Concrete Steel Co., Ltd., of Caxton House, Westminster, by Messrs. S. and J. Smethurst, of Oldham, under the direct supervision of Mr. T. Banbury Ball, engineer and manager of the Rochdale Corporation Gas Works.

NEWS ITEMS.

New Portland Cement Works.

On the Fonmon Castle estates, Aberthaw, the property of Mr. O. H. Jones, a Portland cement works is about to be established.

Cranmer Memorial at Cambridge.

In the chapel of Jesus College, Cambridge, on Thursday last, the Bishop of Ely unveiled a medallion portrait of Cranmer, framed in alabaster carved in a classical design—the work of Mr. Albert Bruce-Joy.

Change of Telephone Number.

The Coatstone Decoration Company wish us to state that, owing to an alteration in the telephone service, their number from July 1 will be 8,316 City, but they are still at their former address—77, Mortimer Street, Regent Street, W.

Proposed New Town Hall for Newcastle.

The proposal to build a new town hall for Newcastle, at a cost of £100,000, on the site now occupied by the Northumberland Baths, is being hotly contested, the main objection being, apparently, to the inclusion of a large concert-hall to accommodate 3,500 persons, and of a small one for 500. An alternative scheme proposes the reconstruction of the present town hall for purely municipal offices.

New Church at Portobello.

St. James's Established Church, Portobello, which was opened last week, has been built at a cost of £5,000 from the designs of Mr. George Mackie Watson, architect, Edinburgh, in the early decorative style of the fourteenth century. The nave is divided into six bays by massive square pillars and high-pointed arches. There are aisle passages at each side, a south transept, and over the vestibule is a gallery.

The New Indian Capital.

The town-planning experts consulted with regard to the new capital at Delhi have now, it is announced by cable, officially decided against the Durbar site for the permanent capital. They have selected a location in the south-western suburbs of the city, which offers good drainage and a fine prospect. The only objection to it is its distance from the recently selected site of the temporary capital.

A New F.S.A.

At the last meeting of the Society of Antiquaries Mr. Arthur Stratton, A.R.I.B.A., Lecturer at King's College, University of London, was elected a Fellow. Mr. Stratton wrote a life of Sir Christopher Wren some years ago, and revised the last edition of Anderson's "Architecture of the Renaissance in Italy." His chief literary work, however, has been in the completion of the monumental book upon Tudor Domestic Architecture, begun by the late Mr. Thomas Garner, which Mr. Batsford published last year.

Canadian Cement Duty Reduced.

The Canadian Government has reduced by one half the duty of 52 cents per barrel on cement. This is because of a shortage of this article in the West, and the order will hold till October 31st. The reduction equals 26 cents per barrel on importations from the United States, 17 cents on cement from Great Britain, and 23 cents on cement from Belgium. At present the importa-

tion of cement into Canada is merely nominal, but the reduced tariff will doubtless effect a considerable and an immediate increase, which is obviously the object in view. Canadian cement manufacturers have lodged a strong protest against the reduction, but Mr. White, Minister of Finance, is convinced that in the West there is a serious check to building operations owing to the inadequate supply of cement.

The "English Bridge" at Shrewsbury.

At a special meeting of the Shrewsbury Town Council, last week, it was resolved to adopt the recommendations of a special committee with regard to the alteration and widening of the English Bridge. This is described as a "narrow camel-backed structure that spans the Severn, known to all motorists as a dangerous bit, but famous as one of the most artistically beautiful bridges in the country." It is to be altered at a cost of £11,430.

Contract for the New London Dock.

The Port of London Authority decided last week that the work of constructing the new dock to the south of the Royal Albert Dock should be offered to Messrs. S. Pearson and Son, Ltd. The cost of the work, based upon the schedule of prices, will amount to about £1,400,000. The contract will include the construction of an entrance lock 800 ft. by 100 ft. by 45 ft. deep; a main dock 4,500 ft. long, averaging 600 ft. in width and 35 ft. in depth, with a water area of sixty-five acres; a dry dock; a passage connecting with the Royal Albert Dock; railway lines and six sheds, but not the working equipment of the dock. On the south side of the dock vessels will be berthed at jetties to facilitate barge traffic.

Wolverhampton's Old Deanery.

At the monthly meeting of Wolverhampton Town Council, last week, correspondence was read respecting the purchase by the Town Council of the deanery site for the erection of a new technical school. The secretary of the Fraser Geological Trust wrote suggesting that the deanery, as one of the historic landmarks of Wolverhampton, should be preserved as a valuable relic—it might be converted into a public museum. Sir Richard Paget, in the course of a long letter, said that the Church of St. Peter and the old deanery were virtually the only architectural evidence of the history of the town, which dates back nearly a thousand years. The fate of the deanery was not decided at the meeting in question.

Town Planning in Walthamstow.

At Walthamstow Town Hall last week Mr. T. Adams, Local Government Board Inspector, held an inquiry into the application of the Walthamstow Urban District Council for permission to prepare a scheme under the Town Planning Act. Mr. Watson, Clerk to the Council, explained that it was proposed to deal with nearly all the undeveloped land in the district, the greater part of which is in the Northern Ward. No estimate of cost had been made, but the Council would act reasonably and would co-operate with the owners. Mr. Naldrett, who opposed on behalf of some of the property owners, said those he represented were willing to develop their land in a proper manner, but they had no knowledge of what the scheme of the Council was to be, and had no option but to oppose. Evidence was given in support of the scheme, and after a four hours' hearing the inquiry closed.

THE LARGEST REINFORCED-
CONCRETE BRIDGE.

What will be the largest reinforced-concrete bridge in the world is to be built across Tunkhannock Creek, near Nicholson, Pa., by the Delaware, Lackawanna, and Western Railroad. The design is for a double-track structure having ten 180 ft. arches with a 100 ft. arch at each end, and totalling 2,230 ft. in length, with a maximum height above the water of 249 ft. The principal arches are to be reinforced, but they are designed to carry loads independently of the reinforcing. The piers are to be carried down to solid rock, about 95 ft. below the ground surface at the deepest point. The centering to be used in placing the large masses of concrete in position is to consist of hinged trussed arches of steel construction supported by the bridge piers. It was decided to have a ballasted floor construction with a thoroughly waterproof deck, and this would have required a heavy design in steel, which, together with the fact that a material increase in live load would produce a less stress increase in the case of a concrete structure, led to the decision to use this material. It was also felt that the maintenance of a steel structure of such height and length was excessive in view of the liability of the rivets becoming loose and of deterioration being caused by vibration. The cost of renewing such a steel structure, owing to the conditions of height and situation, was estimated to be as great as the first cost.

NEW MUNICIPAL WORKS.

The Local Government Board have decided to hold, or have recently held, as the subjoined dates indicate, inquiries into proposed expenditure by public bodies as follows: Water-supply Works.—Bolton Borough Council, £25,000 (June 19th). Sewerage, Sewage Disposal, Drainage, etc.—Birmingham City Council, £1,127 (June 18th); Luton Borough Council, £1,700 (June 20th); East Grinstead Rural District Council, £4,694 (June 20th); Kirkby-in-Ashfield Urban District Council, £12,000 (June 18th); Balby-with-Hexthorpe Urban District Council, £1,673 (June 19th). Street Improvements, Recreation Grounds, etc.—Ashton-under-Lyne Borough Council, £3,200 (June 19th); Llanelly Urban District Council, £5,100 (June 19th); Penybont Rural District Council, £1,700 (June 18th); Birmingham City Council, £1,270 and £24,972 (June 18th); Hastings Borough Council, £1,770 (June 21st); Llantrisant and Llantwit Fardre Rural District Council, £24,500 (June 19th); Southend-on-Sea Borough Council, £2,244 (June 18th). Various.—Bolton Borough Council, £20,000 for electricity undertaking (June 19th); Rawtenstall Borough Council, £7,500 for ditto and £2,600 for extending and heating Market Hall (June 18th); Aberdare Urban District Council, £5,000 for electricity undertaking and £2,260 for laying out burial ground (June 18th); Winchester City Council, £4,361 for cemetery (June 18th); Slough Urban District Council, £2,500 for furnaces for refuse destruction (June 20th); New Hunstanton Urban District Council, for bandstand and shelters, no amount stated (June 18th); Mynddislwyn Urban District Council, £3,555 (June 20th); Pontefract Borough Council, £21,000 for housing (June 13th); Thetford Borough Council, £7,200 for ditto (June 19th).

MOGUL SCREEN FROM DELHI: A WONDERFUL EXAMPLE OF MARBLE CARVING.

The marble, though carved with the intricacy of lacework, is $1\frac{1}{2}$ inches thick. See page 602.

THE ARCHITECTS' & BUILDERS' JOURNAL.

JUNE 26th, 1912.

CAXTON HOUSE, WESTMINSTER.

VOLUME 35. No. 910.

Architects, Clients, and Contractors.

EARLY the whole of the pages of the last issue of the Journal of the Royal Institute of British Architects are occupied with papers and long and elaborate discussions on the position and reciprocal duties and responsibilities of the building-owner, the architect, and the contractor. The discussions represent a perfect maze of differences of opinion, some of which might be put an end to or reconciled by an exercise of common sense and a return to what may be called first principles.

Mr. Saxon Snell, in his very reasonable and moderate paper on "The R.I.B.A. Conditions of Contract," read on April 15th, quotes from a memorandum submitted to the Council by the Practice Committee in 1907. This memorandum refers to the conditions of contract settled in 1879 as having "given considerable power to the architect"; powers, in fact, far too great to please the Institute of Builders, and the present form of contract, drawn up in 1903, was an endeavour to satisfy the builders without injustice to the architect. It was accepted by the Institute of Builders, whether with satisfaction or not we cannot say, but we do know that some of the prominent builders wanted to have every decision of an architect which did not satisfy them subject to outside arbitration there and then, during the progress of the works. This seems almost incredible, but we actually heard this demand made, in conversation, though we should doubt if it was ever formally proposed to the R.I.B.A. The report of the Practice Committee quoted by Mr. Snell went on to say:

"On the settlement in 1903 this [the form of 1879] was altered at the instance of the Institute of Builders. Certain matters dealt with by Clauses 4, 9, 16, 19, and part of 18, were reserved to the architect, but new words were introduced into Clause 30 which had been held to destroy the effect of a certificate given by the architect, and the arbitration clause was also widened so as to lay open to review every certificate whether interim or final, and (subject to certain reservations) every opinion and decision of the architect.

"It has been held by the Court of Appeal in the case of *Robins v. Goddard* (21 Times L.R. 120) that the effect of these alterations is not only to deprive the architect's certificate of all finality as between the building owner and the contractor, but it has also been held by Official Referee Pollock in the case of *Goddard* (building owner) v. *Ferguson* (architect) that an architect who has given a certificate which is successfully challenged by a building owner in an action brought by the builder to recover the amount so certified to be due to him, is liable to repay to his client the building owner the costs incurred in resisting the builder's claim. In giving judgment the learned Official Referee based his decision upon the ground that the architect in his position of agent for the building owner must be held to have contemplated that if he gave a certificate the builder would sue upon it, and that the building owner might resist and incur costs in so doing, and that these costs were within the reasonable contemplation of the architect at the time he undertook to act as such for the building-owner as the reasonable and probable consequences of giving a certificate subsequently held to be inaccurate or excessive.

"The decision appears to carry with it the conclusion that the architect acting under the present authorised Form of Contract is no longer in the position and clothed with the immunities of a

'quasi-arbitrator.' It would also seem to follow that under similar circumstances an architect no longer owes a duty of fair and impartial treatment to the builder."

Mr. Snell characterises the present document as an attempt to revise the previous one "so as to render it more acceptable to our friends the building contractors without giving away the interests of the building-owners. That was a truly conservative policy, and it was no doubt hoped that it would lead to contentment all round. That hope has scarcely been realised, and it would seem that both parties have found, in new and altered provisions, fresh material on which to base quarrels." Mr. Snell thinks that the present Institute form of contract needs very careful revision, and that especially it is too long and complicated—the result of an effort to provide against every possible contingency. It is certainly a lengthy document, but we cannot see that there is any clause in it the purport of which is at all doubtful or difficult to understand. The difficulties, except in one particular, seem rather to arise out of want of attention to them.

Mr. Snell deals with two subjects only among those out of which disputes may arise—the specialist sub-contractor and the arbitration clause. The specialist sub-contractor is an element which has arisen from two causes—the hurry of modern building and the greater complication of things required. It is necessary that some special services—hot-water heating, for instance—should be put into the hands of firms specially concerned with that class of work, and able from their practice and resources to carry it out both well and expeditiously, and in general a firm is selected in which the architect has confidence. Then arises the question, what is to be this firm's relation to the general contractor, and who is to pay him? Clause 28 of the Institute contract gives the option that he may be paid by the general contractor, or directly by the building-owner. We concur with Mr. Snell in thinking the latter alternative undesirable; it complicates matters and leaves the specialist too independent of the general contractor, whose interests he may injure by delay in his work. Mr. Snell's own practice is to nominate the special firms and fix the net amount they are to be paid, but to give them to understand that they look for payment to the general contractor, who is solely liable. On the other hand, he has a provision in the contract that the general contractor must pay to the specialists such payments as the architect shall certify from time to time, and that these amounts are not included in any payment to the general contractor until he produces evidence that they have been paid. This seems a simple and logical method of dealing, and though Mr. Snell says, a few sentences earlier, that it is hardly safe to give the general contractor power to withhold payment in order to speed up a dilatory specialist, this arrangement would practically give him that power. On the other hand, we notice that the chairman for the evening, Professor Blomfield, stated that he always made separate contracts with specialist firms, and dealt with them directly, and thus, as he said, he saved his client the profit which the general contractor charged on the sub-

contract. We should question, however, whether he really effected any saving in that way, and the position seems not quite fair to the general contractor.

But the most serious fault in the present Institute form of contract, in Mr. Snell's opinion, is that the architect is reduced to being a mere agent of the building-owner. In the opening of his paper Mr. Snell advocates the search for a form of contract which shall be based "on the real as opposed to the conventional relations between building-owner, contractor, and architect," and what these "real" relations are or ought to be we presume is indicated in the following paragraph:—

"There used to be a clear distinction, in our relations to the building owner, before and during the carrying out of a contract. In the first place, we were his expert advisers in determining what forms the realisation of his desires should take, and his agents in drafting these forms for the purpose of instructing the building contractor. So soon as a contract was entered into between the parties, to our duties as agent to the building owner in superintending the work was added the honourable one of arbitrator upon points of dispute between him and the building contractor."

Mr. Snell goes on to say that this duality of positions is practically recognised to a great extent, for that many contractors care little about the conditions of contract they sign so long as the architect is one in whom they have confidence, while some of them would accept no form of conditions, however apparently favourable, under an architect in whom they had not confidence, and of course want of confidence may not necessarily arise from a doubt of the architect's probity, but from a doubt of his judgment. We have always been of opinion that the architect was the natural and proper arbitrator between the building-owner and the contractor, but any one who professes that view will very likely hear the remark (as we have heard it) that "the times are past for that now," which means that the builders will not now agree to the architect being general arbitrator—not formally and in documents, at all events, though, as Mr. Snell remarks, many of them act upon it in practice.

The opinion of lawyers seems to be to regard the architect as merely the building-owner's agent; apparently they do not like the idea of an architect acting the part of arbitrator, a function which they regard as especially belonging to the law. On the other hand a legal opinion was more than once quoted in the course of the discussion to the effect that the architect is only an agent until it comes to delivering the final certificate of payment due to the contractor, and that in delivering that he becomes an arbitrator. Surely this is wrong. He is practically an arbitrator every time he delivers a certificate, for in doing so he is exercising his judgment as to the amount of the work done up to that moment, and as to whether it has been properly done or not in accordance with the terms of the contract. If he considered it had not been properly done, he would be justified in withholding the certificate till anything deficient in the work had been made good. And what is that but acting as an arbitrator?

As Mr. Snell says, in the old form of contract the architect's certificate was an "award" from which there was no appeal (except on grounds of fraud or collusion) by either party. Under the present arbitration clause in the Institute form of contract no decision of the architect binds either party, and the architect may be sued for exercising his judgment in a way which may not be endorsed by the arbitrator. The building-owner's case is that he has agreed to pay a certain sum for a building constructed according to definite plans and instructions; that he is entitled to the exact fulfilment of the contract; and he relies on the architect to see that it is so fulfilled, and pays him for so doing. Mr. Snell says that the reply of the architect is that the remuneration received is not sufficient for the close and constant supervision which would alone enable him to say with certainty that every part of the contract had been fulfilled; and that he can only say that "to the best of his knowledge and belief," gained from general inspection, the contract has been properly carried out. Judges in courts of law have often declared that for a professional man to have acted to the best of his knowledge and

ability is all that the law really requires of him. It has been frequently pointed out by judges that the law does not demand of any professional man that he should never be mistaken; it only demands that he should be proved to have done his best and to have acted with *bona fides*. There is that degree of legal protection probably forthcoming for the architect, judging from the analogy of previous utterances from the bench. But in the case of things that are of the first importance in regard to the structure of a building it may be replied that he is bound to know of any important defects. In regard to one case we observe that both a lawyer and an architect, in the course of the discussion, agreed that the deviation from what the architect had (rightly) ordered was so decisive and so important in its deleterious effect on the building that the architect ought to have known of it; that is to say, ought to have assured himself that his orders were being carried out. That was one of Mr. Greenop's cases in which the architect was represented as a victim, a view from which we dissent. We remember a case in which a colonel of a regiment was dismissed from his command in consequence of the existence of serious irregularities among the junior officers of the regiment. The defence was that he knew nothing of these proceedings. The judgment of the court-martial was that that was the essence of his fault; that as commanding officer he ought to have known of them; and the same argument may apply in the case of architects. An architect cannot know every little thing that goes on in a building, except through the medium of a competent and zealous clerk of works; but things that are of great importance he ought to know about. It would be bad for the standing of the profession with the public for an architect to defend himself from responsibility for an important failure in a building by saying he did not know of it. It would lead the public to raise the question—What is the use of architects?

Against the legal dangers to which architects are now subject Mr. Snell thinks there are only two means of immunity. One is to restore the position of the architect as sole arbitrator between the building-owner and the contractor. We quite agree that that is his proper position; that is what he used to be, and ought to be now; but how is the restoration to be effected? It would require, apparently, the agreement of the builders to it; and will they agree? It may perhaps be perceived, on full consideration, that in actual working it would really, in the long run, be better for them; for it must be remembered that a competent and well-judging architect, in the position of arbitrator, is not only concerned to compel the contractor to carry out his work properly, in the owner's interest, but also to protect the contractor against unfair demands on the part of the owner. We are strongly inclined to think that the builders would find it, on the whole, to their interest to again accept the architect as perpetual arbitrator; and it would simplify procedure immensely.

Mr. Snell's other suggestion is that the architect should employ, pay, and be responsible for the clerk of works; though he would have to raise his commission to enable him to do this; and that may not be such an easy matter. The position of the clerk of works is no doubt at present rather an anomalous one. He is chosen, as a rule, by the architect, and is the servant of the architect, but is paid by the building-owner. There have been cases where architects have appointed one of their own staff, generally a pupil nearly at the end of his time, as clerk of works; an excellent thing for the pupil, who no doubt acquires a great deal of practical experience in that way; but whether it is exactly fair to the building-owner is another question. To be a good and reliable clerk of works requires a great deal of practical experience on buildings, and is an occupation in itself, for which special training is needed. But as he is really appointed to give a degree of direct supervision to the building which the architect cannot give, and is really there to carry out the architect's orders, there would seem to be a fitness in his being actually engaged and paid by

the architect, instead of acting under one man and being paid by another. It is at all events a point worth consideration. We should mention that Mr. Snell's proposal for the architect to become responsible for the clerk of works is coupled with the suggestion to insure against the responsibility; which could no doubt be done.

The Architect Poseur.

THE architect poseur—what a type! There are, it is true, not so very many of his kind, because it requires a certain smattering of cleverness to take on a pose. But those who already grace the profession in this manner are all-sufficient. The poseur in architecture is a man who affects one of two things; either he puts himself forward, with no lack of self-confidence, as a tremendously important person, who has an intimate knowledge of things professional and otherwise, or he adopts a languid, expiring attitude towards the art he ostensibly practises. And of the two conditions perhaps the latter is the worse. Can we imagine Sir Christopher Wren surveying his design for St. Paul's with a dreamy air of its too-too-preciousness? or can we imagine some of the leading architects in America to-day dallying with a pencil over a drawing board like some "Grosvenor Gallery, foot-in-the-grave" young men? Of course, the whole affair is ludicrous. Architecture, after all, is a matter-of-fact work of design, and it needs to be regarded as such in a sane, straightforward, vigorous way. Enthusiasm, certainly, and imagination to raise it from the dead level of the commonplace: but let us have done with all pose in regard to it. There is indeed a good deal of cant associated with Art, which is very damaging to artists and their work, and the sooner it is got rid of, the better for all concerned.

The Preservation of Ancient Monuments.

THE evidence given by Mr. Peers, Inspector of Ancient Monuments for the Office of Works, before a joint Committee of the Houses of Parliament last week, brought out forcibly the unsatisfactory state of things existing at present. The Ancient Monuments Consolidation and Amendment Bill only affects monuments that are no longer in use. Buildings used for religious purposes are definitely excluded. Mr. Peers mentioned the case of St. Albans Cathedral, where what was done was in opposition to the whole feeling of the country, yet no one could do anything to stop it. The real fact, however, is that the Chancellor of the Diocese had full power to stop it, but failed to understand the importance of the case. He thought that any man who offered to find the money to restore a cathedral had *ipso facto* a right to restore it himself in any way he pleased. We doubt, however, if this could be done a second time. Public opinion has been more educated on the subject since the days when St. Albans was handed over to the tender mercies of the late Lord Grimthorpe, and a Chancellor who allowed an incompetent person to handle a cathedral as if it were his own property would raise a public clamour which would make things a good deal too hot for him. But in regard to historical monuments not in actual use the case is different. Their value is not so easily understood by the general public as that of a cathedral or other great architectural monument. According to Mr. Peers there is at present nothing to prevent Stonehenge going across the Atlantic, if the owner chose to sell it to an American millionaire. The "preservation order," by which the Commissioners of Works could place a monument under their protection, only applies where there is danger of destruction of a monument by damage from neglect or injudicious treatment. Apparently it does not prevent a sale by the owner to some one outside the country. Mr. Peers suggests that the Advisory Committee should look ahead and make a list of monuments which ought not to be touched under any conditions. It is to be hoped this advice will be acted upon. It is really lamentable to think that monuments which are part of the history of

the country are at present at the mercy of the caprice or cupidity of private owners who may be tempted to part with them for money.

In connection with this matter we may mention the report circulated last week that the magnificent old staircase in Cromwell House, Highgate, was to be sold to an American and taken out of this country. There appears to be some doubt about the authenticity of this report, but, having had the case of Tattershall Castle so recently before our notice, we may well feel some uneasiness when rumours of a similar character are spread in connection with the Cromwell House staircase. The committee of the Hospital for Sick Children in Great Ormond Street are the holders of the lease of the house, which is now used as a convalescent home, and they make the very good suggestion that the building should be acquired for the public, and the adjacent houses cleared away. The staircase and other woodwork within the building are certainly very fine examples of Jacobean work, and an effort should be made to preserve them once and for all.

Fortunes and Misfortunes in the Building Trade.

OF late there have been so many heavy pecuniary failures in the building trade that it is a relief to place on record any incident of opposite character, even though the opportunity to do so is usually marred by a touch of melancholy, since the measure of a man's financial prosperity is not definitely revealed to the public until after his death. With this decent reservation duly observed, there is pleasure in noting that the late Mr. Frederick Ingle, contractor, of Grant-ham, Nottingham, and London, who died on May 30 last, aged seventy-three years, has left estate of the substantial value of £160,149. It is gratifying and reassuring to assume that most of this fairly large fortune was yielded, within a comparatively recent period, by the building industry, which of late has been chiefly distinguished by the extraordinary number of its "failures"—some of them of colossal extent—in comparison with those that occur in other businesses. As to the disproportionate number of bankruptcies, the building trades easily keeping at the head of the list, we have repeatedly indicated some of the principal causes of that bad eminence. We have often suspected that this position would possibly not be so steadily maintained—that the building industry would at least occasionally appear lower down the dismal list—if the order were regulated by the amounts of liability rather than by the numbers of the persons liable, these numbers being greatly inflated by an extraordinary preponderance of "little men," or "men of straw," who take advantage of peculiar facilities for entering the business with very inadequate capital, or possibly no capital at all. An enormous percentage of these adventurers are mostly aspiring journeymen, possessing a little experience but no capital, with a fair sprinkling of rank outsiders, having a little capital but no experience, both conditions trending in a bee-line to the bankruptcy court. Such persons merely "start in business," and the Official Receiver does the rest; and these minor disasters are so numerous as to cast an unfair aspersion on a trade which, to do it justice, needs no exaggeration of its precariousness. The trade has, indeed, its own inherent and inveterate frailties, such as feverish competition and the prevalent neglect of scientifically sound and rigorously pursued book-keeping; the master builder who is able to say at any hour, as he should be, exactly how he stands financially being quite scandalously exceptional. The present moment, however, would be inappropriate for applying the test of relative aggregate liabilities, as recent huge failures of contractors would swell the account abnormally. Some of these colossal crashes have been brought about by mere dilatoriness in settlement by building owners, or by the locking-up of the builders' capital in some other unfortunate way; but this matter has been, at various times, dealt with exhaustively in these pages, with the consequence that builders have bestirred themselves in the direction of a much-needed

reform. Anyhow, it is to be hoped that the happy secret of making a fortune in the building trade did not die with Mr. Ingle. It is delightful to find that this gentleman knew not only how to make money extensively, but how to bequeath it generously, and with grateful recognition of the services of those who helped him, in various capacities, to amass his fortune. Not only has he left £35,000 to be disbursed, at the sole discretion of his executor, among charitable institutions, or for charitable objects, in sums not in any one case exceeding a thousand pounds, but he has directed that various amounts shall be awarded to a large number of his employes—as £1,250 to his London manager, £300 each to three draughtsmen, £250 to his accountant, and the same sum to the widow of his late engineer; £200 to a clerk, £100 to the widow of a foreman, £250 each to two foremen concretors and to a foreman erector; £200 each to a foreman erector, a yard-man, a carman, and an office porter; £500, £300, £200, and £100 to clerks at Nottingham; £300 to a shop-foreman there, and £200 to the saw-mill man, with several minor bequests. Possibly there may be as much wisdom as kindness in distribution of these legacies; but, at any rate, it is reassuring to find that the building trade is still—or was in the immediate past—sufficiently profitable to make them possible.

The Cheapening of Cottages.

THE keen desire of rural councils to build cottages so cheaply that they "can be let at a price within the reach of the farm labourer" grows almost pathetic in its intensity. They yearn to put up cheap dwellings, but are continually baulked by the inelasticity of the by-laws, which insist on the dwellings being decent, and the indigency of the labourers, which is imperative that they shall be cheap. Sometimes they have enough courage to defy the by-laws, but they have never enough to defy the ratepayer, and, in his interests, they are also abjectly in bondage to the inexorable laws of arithmetic, which show that a cottage costing say £150 to build cannot be logically let at as low a rent as one that cost only £120. As the labourer cannot pay the higher rent, it then becomes a question whether his interests or those of the ratepayer are to prevail, and the answer to it usually leaves no doubt as to whether or not this is the age of chivalry. But even a rural district council does not invariably move along the line of least resistance. More often it does not move at all. An exception to both these unheroic policies is worth chronicling, more especially since it includes a sound decision on a question of architects' fees. St. Thomas Rural District Council, at their usual fortnightly meeting, held at Exeter, had under discussion the cost of a few cottages which they propose to build, and the rate of remuneration that the architect is to receive for his share in the work. An architect was appointed, and it was agreed that he should receive the usual fee of 5 per cent. for his services, notwithstanding an offer by another firm of architects "to do the whole thing for 3 per cent., including out-of-pocket expenses." In supporting this offer, a member of the council said it was not the difference between 3 and 5 per cent. (which would not be a great matter on a total outlay of £400) which actuated him so much as the fact that the 3 per cent. firm had had experience of several similar schemes. In one such scheme that the speaker specified the builder's contract was £120 per cottage. This member seems to have been labouring under some slight misapprehension as to the functions of an architect, who, after all, has no very great control over contract prices, which, specify he never so wisely, depend very much more upon local conditions than upon economy of design. In so paltry a scheme, it is not worth while to quibble about the difference between 3 per cent. and 5 per cent., although, as a matter of general principle, we should much prefer to see architects not only claiming the recognised fee, but in other ways discountenancing the cheapening of building. We see no real necessity for ultra-cheap cottages, and have no belief in its actual existence.

PRACTICAL CONDITIONS OF ORNAMENTAL DESIGN.

IT is not quite obvious at first sight why Mr. Woolliscroft Rhead has entitled his book on ornament "Modern Practical Design."* We do not know of any such thing as theoretical design; but a look through the book explains the second adjective, for the object evidently is to consider design for various classes of materials in relation to the practical nature of the material and of its manufacture in each case. But why "modern"? We presume the explanation lies in the position set forth in the first chapter, that "a systematic study of plant form, if it became at all prevalent, would undoubtedly tend to the formation of a new style of ornamental art." This idea, however, is certainly not new. Various artists and writers on art have at different times pointed out the amount of suggestion for ornamental design which may be obtained from a close study and drawing of natural forms—J. K. Colling and Lewis F. Day, for instance; and the first-named artist really extracted some novelty of style in ornament from his studies of natural leafage. Nor do we believe that basing everything in ornament on the study of natural forms would really lead to the foundation of a new school of ornament.

In the first place, it is to be remembered that there are two schools of ornament—that which is founded on a relation to natural forms and that which is entirely abstract and founded on geometry. Some of the best ornament that has been produced has been of the latter class; much of the Byzantine and Saracenic ornament, for instance. And when we come to natural forms, it must be remembered that ornament cannot come too close to nature; it requires to be conventionalised into a systematic form; if it is too close to nature it becomes merely imitation, not design at all. And the process of conventionalising necessarily does away with some of the smaller details which make the differences between natural forms. Nor can we agree with the author that ornament is an all-pervading principle in nature. Nature is beautiful in detail in a thousand ways, but she does not design nor apply ornament on a principle or system.

* "Modern Practical Design." By G. Woolliscroft Rhead, R.E., Hon. A.R.C.A. London: B. T. Batsford; 1912. Price 7s. 6d. net. 8½ in. by 6 in.; 247 pp.

CARTOON FOR STAINED GLASS, "THE SONG OF SONGS,"
BY BURNE-JONES.

It is Man who designs, not Nature; and the best ornament that has ever been produced has been, on the whole, the furthest from the imitation of Nature.

The author's main position, and his promise of a new school of ornament based on a closer study of natural forms, is therefore an illusion. And there is another general principle, or general statement, which we must dissent from entirely; the insinuation that "pictorial art has arrogated to itself an importance out of all proportion to its real value." We have had this contempt for pictures expressed by various ornamentists, and it is a complete fallacy. A good landscape or figure painting has an intellectual interest beyond what can belong to any form of merely ornamental design, and demands higher powers and training for its production.

But the fact that the author is, as we think, misleading in what may be called the philosophy of his subject, does not detract from the interest and usefulness of his book in a practical sense. To describe and illustrate the type of ornament best suited to a number of different materials, and in each case to give a practical description of the nature and capabilities of the material, and the manner of its manufacture, is a very large programme to carry out within the compass of a comparatively small book; and within these limits it is very well done, and in a manner that argues an extensive technical knowledge on the part of the writer. The chapters on "Plant form as the basis of ornament" only go through what has already been suggested by other writers, and their study will not make an ornamentist; for success in ornament depends on the designer himself much more than on a nature basis. But the chapter on "The ornamental filling of given spaces," one of the most important problems in the disposition of ornament, is a very good one, and the diagrams offer many useful suggestions.

With the chapter on the "all-over patterns" in wall-papers and different classes of textiles we come on some of the matter that makes the real value of the book, the nature and the method of manufacture of each material being considered with reference to the nature of the design best suited to it. In regard to textiles used as hangings, the author rightly says that the foldings should be taken into consideration in making the design; that bold curves and horizontal setting of the design serve to emphasise the foldings, and vertical lines are objectionable. We should go a step further, and lay it down as a rule that no formal geometrical patterns should ever be attempted for hanging textiles, as such designs can never be properly seen in their complete form; they are broken up by the foldings. The design has to be a repeating one, but it should be so far informal in detail that if only a portion of a repeat design is seen in a fold, it should not appear as if incomplete. Carpets, on the other hand, are a kind of mosaic in soft materials, and symmetrical design can be perfectly well used in them, as it will be fully seen and not wasted. In regard to book decoration, while it may be admitted that in the author's diagrams of "page proportioning" the arrangement which he prefers looks very well, yet it is hardly very practical, for it involves the loss of a great deal of space on the page, which may materially increase both the cost and the bulk of the book. After all, a book is primarily something to be read; the decorative appearance of the page is a secondary matter, and should not interfere with the usefulness of the book.

In the chapter on stained glass the technique of the work is very well described in a short space, but something more might have been said about the manner of using the leading. It is possible with white glass only to make very interesting line designs out of the leading only, which is then treated as forming the design in itself. But with a coloured window the leading is only a division between the colours, and should never pretend to form in itself part of the design, otherwise there is a confusion of idea as to the function of the leading. The design by Burne-Jones, given on page 155 of the book,

INLAID LECTERN, BY ERNEST W. GIMSON.

is very faulty in this respect. The framing of the door, and the hinges, are too decidedly defined by the leading, and are shown in perspective; although what seems to be intended for the large mediæval keyhole of the door is not in perspective, but faces one, defined by the leading, which thus seems quite at variance with the rest of the design. The effect is very confusing, and, in spite of the distinguished name of the artist, we cannot call this a good piece of stained-glass design.

"Metal Work and Jewellery" is a good short chapter, and in this class of subject there is much to be said for the hints that actual flowers may give for jewels and enamel. "Dress embroidery" and "Posters" are very fascinating subjects; but hardly within our proper province. The author's design for a fancy dress founded on canary creeper, however, illustrates our position that the imitation of natural forms is not ornamental design; this costume simply consists in copying the forms of the leaf of the flower referred to, placing them on the head of the figure, round the bust and shoulders, and in a much enlarged form round the lower margin of the skirt; these latter are quite out of scale with the rest. That kind of work is hardly ornamental design; it is merely the application of natural leaf-forms to a dress.

The book is of value for the extent of technical information about materials and processes contained in it, all which is useful to a learner in design and justifies the word "practical" on the title-page. As we have given one example of an illustration we do not like, we add other—an inlaid lectern by Mr. Gimson—which we can fully approve.

LEGAL.

Principal Contractors' and Sub-Contractors' Liability for Accident.

In the Court of Appeal on June 21, Lords Justices Fletcher Moulton and Buckley and Mr. Justice Parker heard an application in the case of Padbury v. Holliday and Greenwood, Ltd., and another, in which the defendants, Holliday and Greenwood, Ltd., sought judgment or a new trial in an action tried before Mr. Justice Coleridge and a special jury on February 16.

The action was brought by the plaintiff against Holliday and Greenwood, Ltd., and Wainwright and Waring, Ltd., to recover damages for personal injuries sustained by the plaintiff while passing along the highway through the alleged negligence of the defendants. The defendants, Holliday and Greenwood, Ltd., denied negligence, and in the alternative said that if there was negligence, it was not their negligence, but that of their sub-contractors, Wainwright and Waring, Ltd., in failing to provide a shield or other suitable protection to the public. The latter did not enter an appearance to the writ, but eventually the plaintiff discontinued the action against them; and it appeared that, on January 4, 1911, when the plaintiff, Mr. A. G. Padbury, was passing down Fenchurch Street, a piece of iron fell from the third floor of a building then being erected by the defendants, Holliday and Greenwood, struck the plaintiff's head, and injured him.

On the findings of the jury in the Court of first instance, judgment was given for the plaintiff for £500. The defendants now applied for judgment or a new trial. The Court allowed the appeal, and ordered judgment to be entered for the defendants.

In the course of his judgment, Lord Justice Fletcher Moulton said that in this case building owners employed the defendants, Holliday and Greenwood, the present appellants, to erect certain premises for them, and the contract involved the employment by Holliday and Greenwood of sub-contractors to execute special works. The work of putting metallic casements into the windows was entrusted to Wainwright and Waring. While one of the casements was being put in, an iron tool was placed by a workman in the employment of Wainwright and Waring on the window-sill, and, the casement having apparently been blown to by the wind, the tool fell and struck the plaintiff, who was passing along the street. For the injury so caused to him the plaintiff sought to make Holliday and Greenwood liable. The case thus raised the question of the responsibility of a contractor who employed a sub-contractor for injury done to a stranger through the negligence of a servant of the sub-contractor. Although the view which the law of England took of this question had undergone some transformation, he did not think there was any doubt as to the general principle which now prevailed. After referring to the precedents of *Dalton v. Angus*, and *Quarman v. Burnett*, his Lordship said that, on the authority of Lord Watson's judgment in *Dalton v. Angus*, he was of opinion that before a superior employer could be held liable for the negligent act of a servant of a sub-contractor it must be shown that the work which the sub-contractor was employed to do was work the nature of which, and not merely the performance of which, cast on the superior employer the duty of taking precautions. The injury here was caused by an act of collateral negligence on the

Photo: Record Press.
GANTRY FOR NEW BUILDING OF H.M. STATIONERY OFFICE, STAMFORD STREET, LONDON, S.E.

part of a workman who was a servant of Wainwright and Waring and not a servant of Holliday and Greenwood, and Holliday and Greenwood were not liable for the consequences of that negligence. He therefore thought that the appeal should be allowed, and entered judgment for the defendants.

Lord Justice Buckley and Mr. Justice Parker delivered judgment to the same effect.

A NOVELTY IN BUILDING
CONSTRUCTION PLANT.

On a site in Stamford Street, London, S.E., there is now in course of erection a new building for H.M. Stationery Office. The area has been cleared, the foundations have been built, and a start has been made with the superstructure, which is to be of reinforced concrete. In connection with the work a decided novelty has been introduced in the form of a gantry covering the whole site. We publish a photograph of it on this page. So far as we are aware, such a gantry has never before been employed for the erection of a building, though it is usual to find similar structures in shipbuilding yards. We hope later to publish detailed particulars of the work and to give some definite information as to the idea of those who have introduced it: but, meanwhile, we may assume that the object of the gantry is to save time and money, and it will be interesting to know whether in the end this result has been achieved. The gantry consists of nineteen lattice steel stanchions nearly 90 ft. in height, supporting girders at the sides and ends, and will eventually be fitted with travelling cranes for handling the material. It has cost some thousands of pounds to erect. Messrs. Drew-Bear, Perks, and Co., Ltd., are responsible for the steel work, the general contractors for the building being Messrs. Perry and Co. (Bow), Ltd.

CORRESPONDENCE.

The Editors disclaim all responsibility for the statements made or opinions expressed by correspondents. Correspondents are asked to be brief and to write on one side only of the paper.

Cross-Lighting and Ventilation.

To the Editor of THE ARCHITECTS' AND BUILDERS' JOURNAL.

SIR,—Referring to the interesting review of Mr. Robson's book in your last issue, there are one or two points in which I would like to join issue with your reviewer.

After several years of cross-lighting, I am still of opinion that the advantages to be gained far outweigh the disadvantages. Moreover, it is difficult to understand how one can get efficient cross-ventilation unless one has windows on opposite sides brought down to the same level near the floor.

To obtain efficient ventilation it is, of course, understood that every room must have two external and opposite walls which can take the wind-pressure. With reference to Fig. 3 on page 624 of your last issue, assuming that the bottom of the plan is the south, and assuming also that the wind blows from the south, what wind-pressure would be felt on the windows between the hall and the classroom? Practically none. In a school on the open-air principle, the south wall of the classroom would receive the full pressure of the wind, and the change would therefore be rapid. With a plan of the type shown in Fig. 3, I am prepared to admit that natural ventilation would not supply the requisite amount of air under all conditions.

With reference to the "Plenum" system of ventilation, I quite agree with Mr. Robson in his remarks. Given the "Plenum" system, every door and window has to be kept shut, otherwise the system does not act, or does not act properly.

Your reviewer states that without mechanical ventilation, it is impossible to obtain the requisite amount of air for schools. With this I cannot agree. I am often carrying out experiments, and as recently as June 18 I carried out some further experiments before a deputation from an important northern county, and completely proved that sufficient air was brought into the schools. This was obtained by means of hoppers only. The wind outside was blowing at a rate of just over four miles per hour, but sufficient air was coming through the hoppers only to change the air in the room ten times per hour, and that without any draught being felt. This rate of change was sufficient to supply a room containing sixty children with 1,500 cubic feet of air per hour per child. Subsequently the room was filled with smoke, and then all the windows were opened. In three minutes the air inside the room was as clear as the air outside.

If your reviewer is in Derbyshire at any time, I shall be very happy to go round with him, and I hope prove that natural ventilation is not only as good as, but far better than artificial.

GEORGE H. WIDDOWS, A.R.I.B.A.,
Architect to the Derbyshire Education
Committee.

June 21, 1912.

[We considered mechanical ventilation necessary, or, at all events, the most efficient, for large and crowded schools, as for all large and crowded buildings; small schools may do very well without it. A complete test of purification of air can only be made by microscopic examination of the air, as was done in the case of the Scotch school to which we referred. The mere appearance of a clear atmosphere is not conclusive; the most serious impurities may be those which cannot be detected by ordinary vision. The question is open to differences of opinion, but those who recommend mechanical ventilation are not to be called "faddists"; they are people who are relying on scientific demonstration.—ED. A. AND B. J.]

SOCIETIES AND INSTITUTIONS.

Institution of Gas Engineers.

The annual meeting of the Institution of Gas Engineers was held recently, under the presidency of Mr. R. G. Shadbolt, of Grantham. Mr. Corbet Woodall was elected president for the ensuing year.

In the course of his address the President referred to manufacturing processes, and said that whereas not many years ago invention in carbonising methods was almost at a standstill, now the ordinary managing engineer who was on the point of extending his plant had a selection almost bewildering in its variety of method and rivalry of claim. The advent of the vertical retort in its various practical forms had quickened insight into carbonising methods generally, and the reflex action upon older systems had been most beneficial.

There was also an unmistakable movement in the condensing, washing, scrubbing, and purifying processes. Agreement in the main functions of condensation, its limitations and effect upon subsequent treatment of the gas, was much more general than formerly, with the result that there was greater control of condensing appliances—as in the growing use of the water-cooled types, and the separate treatment of gas for the removal of tar and tar vapours which mere reduction of temperature failed to effect. In washing and

scrubbing methods signs were not wanting in some quarters of a return to favour of the tower-scrubber. The application of centrifugal treatment to the washing, scrubbing, or purifying agent was also making advances; and, in common with carbonising methods, all purifying processes, from the hydraulic main to the station-meter, were showing unmistakable signs of development in numerous directions.

The question of long-distance supplies had assumed a new importance under high-pressure conditions. Many of the objects and purposes to which gas supply was applied were fully realised, and served under comparatively low-pressure systems, but low pressures in the general supply did not provide sufficient range of action, and whereas it was but a matter of mechanical adjustment to reduce from a higher to a lower potential, the conditions surrounding the contrary process were often prohibitive. Once the initial pressure of gas delivery was placed constantly above that required for all working purposes, the first step towards an infinitely wider field of application would be taken. From this point forward the requirements changed with bewildering variety, and the altered requirements were evolving a distinct class of gas engineer, who had certainly not the least interesting or important sphere of operations. Primarily a purveyor of potential heat energy in one of its cleanest and most concentrated forms, he had the important function of applying it to all kinds of purposes, domestic and public, industrial and commercial.

THE STREET NAME-PLATE PROBLEM.

The article on the street name-plate problem in the JOURNAL of June 12th has been widely quoted and commented upon, and among the communications that it has evoked is one from Messrs. Doulton and Co., Ltd., of the Royal Doulton Pottery, Lambeth, S.E., who send illustrations (one of which we reproduce) of their stoneware lettered tiles, as supplied to the London County Council, and to various borough and district councils. For use as street name-plates, or for the designation of houses, these tiles can be assembled to form any required name, each tile carrying a separate letter. The lettering, as will be seen from the sample given, has the supreme merit of legibility, as well as considerable elegance in the design; while the form of the letter has been so well considered as to render the spacing quite satisfactory in every combination. The street-name tiles are $5\frac{1}{8}$ in. high and $3\frac{1}{4}$ in. thick, and have a key back for fixing, as have also the house-labels, which are $3\frac{3}{4}$ in. high. The tiles can be used with or without frame-moulding; and a great advantage of the system is the permanence of the colouring, which can be kept bright by simple cleansing. The firm supply other forms of ceramic letter tablets and signs, as well as stoneware panels of large dimensions and special design. Many such special designs, we understand, have been supplied to large and important buildings, such as town-halls, banking premises, hospitals, etc.

OUR SOUTH AFRICAN EXPORT SUPPLEMENT.

With the present issue is included, without extra charge, a 28-page SOUTH AFRICAN EXPORT SUPPLEMENT, in which will be found an authoritative account of the present position of architecture and the building trade in the Union of South Africa, as well as a brief survey of the architectural history of that rapidly expanding country. It is believed that, from a business point of view also, this Supplement will be highly appreciated both at home and abroad as a valuable means of bringing the respective countries into closer commercial relationship.

PROPOSED NEW MUNICIPAL WORKS.

The Local Government Board have decided to hold, or have recently held, as the subjoined dates indicate, inquiries into proposed expenditure by public bodies as follows: Water-supply Works.—Chelmsford Rural District Council, £6,350, for Broomfield (June 26); Fylde Water Board, £120,000 (June 27); Penzance Borough Council, £2,350 (June 28). Sewers, Sewage Disposal, Drainage.—Sheffield City Council, £13,622 (June 25); Chorley Borough Council, no amount stated (further inquiry, June 26); Yeovil Rural District Council, £3,540, for Stoke-under-Hamdon (June 28); Manchester Corporation, £4,310 for filtering and aerating plant (June 27); Crediton Urban District Council, £16,300 (June 27); Carlisle Rural District Council, £1,250, for Kingmoor and Stanwix (June 28). Street Improvements.—New Roads, Recreation Grounds, etc.—Sheffield City Council, £15,268 (June 25); Chelmsford Borough Council, £4,760 (June 25); Widnes Borough Council, £1,900, £2,600, and £12,780 (June 28); Manchester Corporation, £4,725 (June 27). Various.—Sunderland Borough Council, £37,207 for electricity undertaking (June 26); Leyton Urban District Council, £1,300 for ditto (June 24); Abersychan Urban District Council, £26,000 for housing (June 25); Newbury Borough Council, £2,020 for ditto (June 27); Radcliffe Urban District Council, £13,000 and £13,610 for ditto (June 27); Radstock Urban District Council, £6,600 for ditto (June 26); Featherstone Burial Board, £1,100 for burial ground (June 26); Kingston-upon-Hull City Council, £2,585 for stables, etc., and £1,350 for refuse crushing plant (June 25); South Shields Borough Council, £8,850 (June 25).

The Building Trade Unions.

A private conference of trade unions representing men employed in the building trade was held in London last week to consider the proposed amalgamation of the unions under the title of the Amalgamated Building Workers' Union, with a view to maintaining "a fighting organisation working to improve the conditions of the workers." At the end of the meeting Mr. Bowerman, M.P., stated that the Conference, which represented thirteen unions, had approved the scheme. A ballot of the members concerned will be taken not later than September 30.

STONEWARE NAME-PLATE, BY DOULTON AND CO., LTD.

DETAILS OLD AND NEW.—XLV.

Bay Window, West Mills, Newbury.

Dr. Syntax was not more persistent in the pursuit of the picturesque than many architects are to-day. With what assiduity do they torture brick and mortar, timber and tiles, to the simulation of the merely ancient—the *moderno antico* of Walpole! With what disregard of the vital necessities of life do they proceed! Without headway, ventilation, or light, houses are foisted upon an unsuspecting public. A house or cottage, the original of which was built to harbour labouring men, becomes the home of a stockbroker who finds himself under the painful necessity of adopting the patriarchal life—of, in short, doing something stupid or affected, or living an anachronism in his own house.

The true picturesque cannot be made by the deliberate hand of art. Time alone can do it.

The gable from the West Mills, Newbury, seems to us to be picturesque. Just consider how the tile-hanging is done. One would not recommend anyone to copy it. But the idea of the bay is so delightful; it is such a useful feature, that it would be a pity not to be able to reproduce some of its charm. And certainly it it be accepted for what it is—purely a utilitarian affair—and treated simply, not all the beauty will escape, and, perchance, a new charm may creep in. The relation of this little bay to the gable in which it is set and the contradiction of the lines of

the two gables are pleasant to notice. At the base of the gable can be seen the half-timber construction which probably stood intact for a century or so, until the weather got through its joints and a new builder covered it with tiles and knocked out the bay window from which to catch a glimpse of the Kennet. Like all old tile roofs—older, that is, than the eighteenth century—this one is pitched with an apex at a sharper angle than 90 deg. The verge-board is moulded and projects slightly beyond the face of the tiles. Purlins, which support them, can be seen in the photograph view. As a whole, the gable is a pleasing and uncommon arrangement, and can be easily adapted.

J. M. W. H.

COMPETITIONS.

Sunk Bandstand, Hastings.

Twenty-three designs for the proposed sunk bandstand and colonnade at Warrior Square, Hastings, were submitted. Mr. Philip Tree, of St. Leonards, was awarded the first premium; Mr. Boutcher, of London, the second.

New Building for the Port of London Authority.

The six selected competitors in the final competition for this building, to be erected on the area comprised within Seething Lane, Crutched Friars, and Trinity Square, E.C., will send in their designs on Monday next, July 1st. The names are:

Mr. Robert Atkinson, Mr. Edwin T. Cooper, Messrs. Lanchester and Rickards, Mr. Reginald Truelove, Messrs. Wallis and Bowden, and Mr. Ernest W. Wray.

THE PROJECTED AUSTRALIAN
CAPITAL CITY.

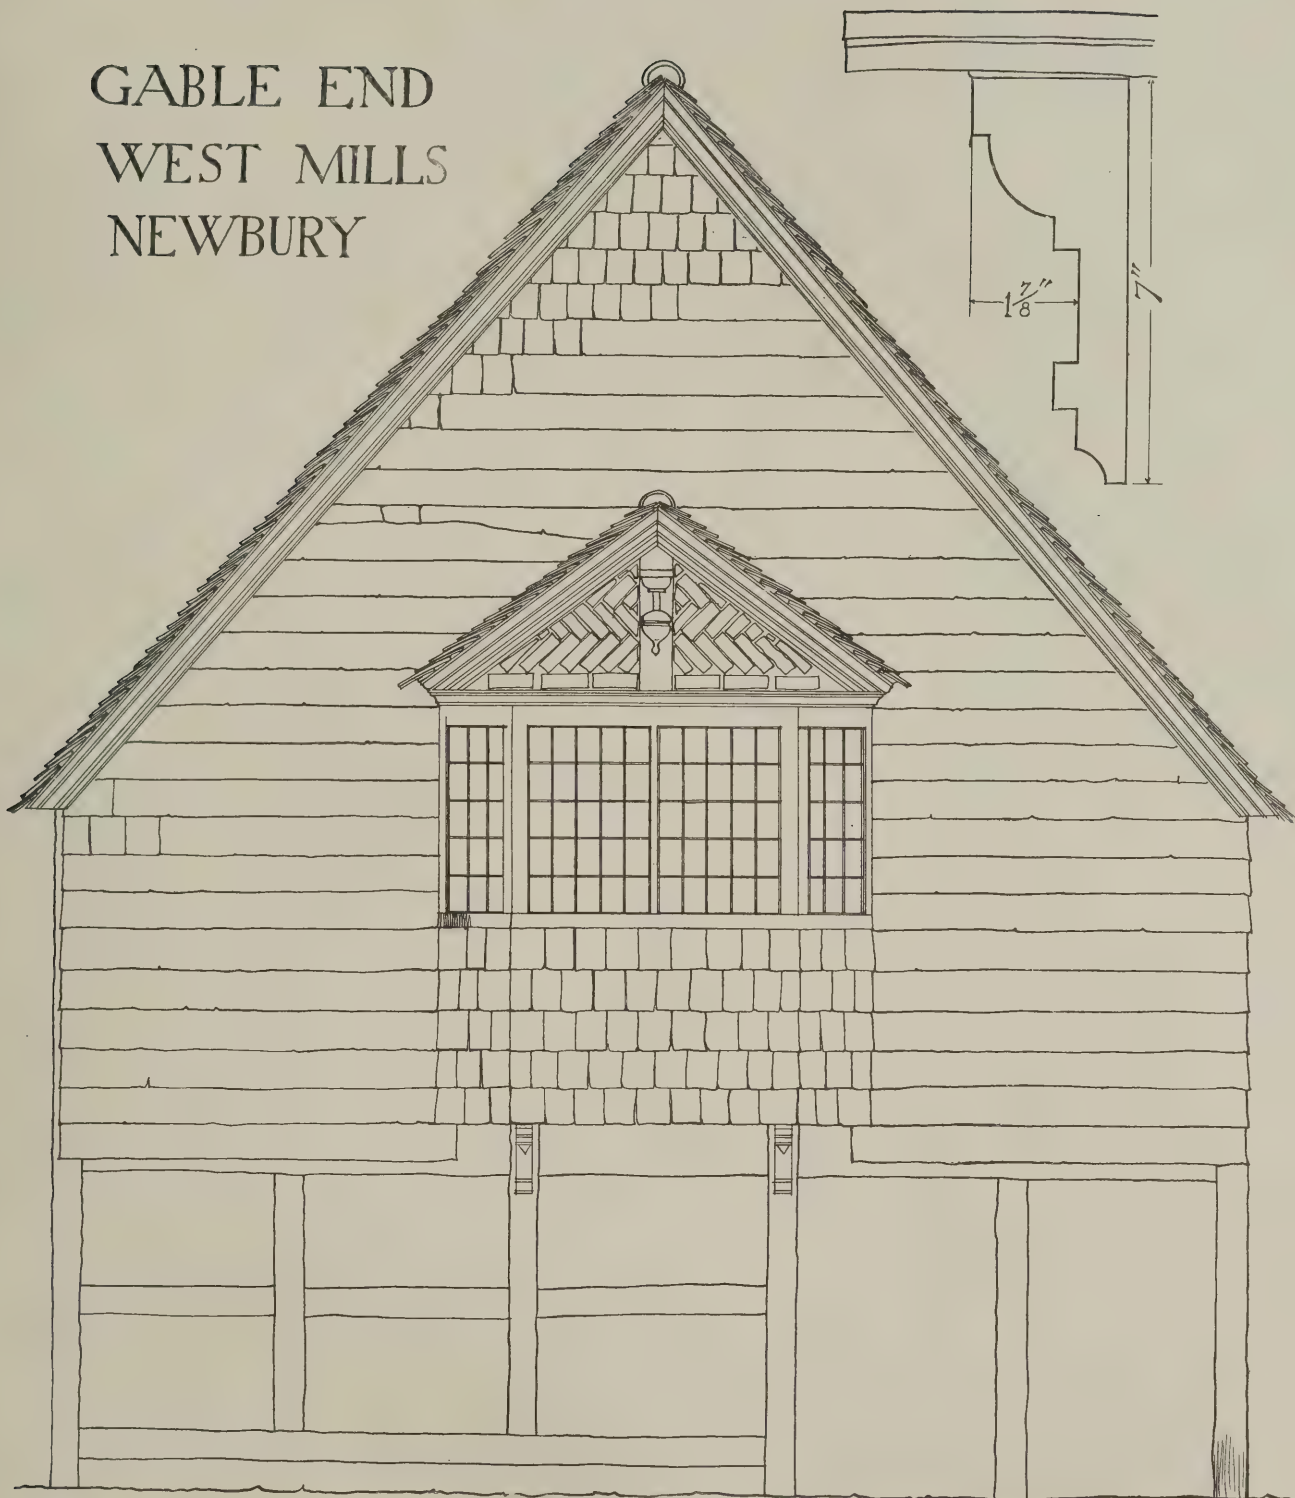

It has been already announced that the first premium for the scheme for the projected Australian capital city at Canberra has been awarded to Mr. W. B. Griffin, of Chicago. *Apropos* of this decision, an Australian correspondent of the "Times" contributes an interesting article on the subject. The site, he says, is a splendid plateau about 2,000 ft. above sea level, situated a little to the north of the highest peaks of the Australian Alps. The northern part, consisting of the plateau on which the city will rise, is to-day spacious and pleasing meadow land, generally undulating. The country is sparsely inhabited, and, as the spectator views it from some convenient vantage point (looking towards the north, for instance, from Mount Stromlo, where the Observatory is to be erected), he sees few signs of what habitation there is. To the right lie the buildings of the Military College at Duntroon, centred round an old farm homestead and already making quite a hamlet of its own. Near by are the knobs called Mounts Ainslie and Majura. From them fields fill up the broad valley that stretches over to Black Mountain, another knob on the left, which rises steeply from the plain and stands out in sharp contrast to other features of the northern aspect. The Molonglo River, a placid willow-lined brook, which flows right through the chosen site, disappears from view at the foot of Black Mountain, and further over to the left, where the larger bulk of Mount Coree fills in the horizon, it slides into the stream of the Murrumbidgee. In the middle of the view from Mount Stromlo the spectator can distinguish the little Canberra church and parsonage, and more to the left the Acton homestead and a few other scattered houses. The waterworks from the Cotter will be on the extreme left hand; the railway to Jervis Bay (seaport and site of the Naval College) and the outer world will run out into the extreme right.

In the winning American plan the Molonglo River is boldly treated, and the city is divided by three large sheets of water, with parks and boulevards. Immediately facing the central lake, on the southern shore, is the official quarter—Parliament Houses and Government Buildings, extending down to the lake front, with streets laid out in octagonal form around them. A fan-shaped residential quarter lies on one side, and on the other are spread in lines following the natural contour the municipal centre, the University, and the industrial centre. The general plan is for radiating streets with connecting crossways. The railway is brought at the back through the industrial, business, and market quarters to a convenient central point. From the Parliament buildings as a centre radiate the main thoroughfares, the direct arteries of communication between the outlying parts of the city. Most of the plans from which the final selection was made followed the radial form. The German idea was for what is described as "a classically built city," with streets in sweeping curves and leaving the Molonglo waters almost undeveloped as compared with the American scheme. The French plan was for a fan-shaped town, rich with elaborate parks and boulevards.

Cannon Street Subway.

The City Corporation are about to proceed with the new subway underneath Cannon Street, opposite the Mansion House Station, for which Parliamentary powers were recently obtained. The work will cost £16,000.

Restoration of Chepstow Church.

The fine parish church of Chepstow, which is of Norman date, is to be further restored. It is proposed to take down an unsightly gallery, to rebuild the north transept to correspond to the south one, and to rebuild the aisles. The scheme is estimated to cost £5,000.

Scaffold Accident.

A master-builder named Green, of the firm of Messrs. Berrill and Green, contractors, of Wellingborough, was fatally injured last week through the collapse of a scaffold at Wollaston Waterworks, he and others being hurled a distance of 50 ft. His partner saved himself by clinging to a pole. Two other men were badly injured.

Removal of a London Statue.

The eighteenth-century statue of the founder, Sir Robert Geoffrey, of the almshouses of the Ironmongers' Company in Kingsland Road, now acquired by the London County Council as an open space, has been removed from its original position, and will be re-erected at the new almshouses to be built by the Guild at Eltham. A replica will be presented to the Council for erection in the garden.

Two Heating Contracts.

The Acme Ventilating and Heating Co., of Liverpool, have been entrusted with the heating contracts for the Council schools in Junction Road, Burgess Hill, Sussex, under the instructions of Mr. F. Wood, A.M.Inst.C.E., county architect, Lewes; they have also secured the heating contract for the new Washbrook Chapel, Hollingwood, Oldham, the architect of which is Mr. H. Kelsall Armitage, Liverpool.

The Old Reindeer Inn, Banbury.

The ceiling and panelling of the Old Globe Room of the Reindeer Inn, Banbury, are in course of removal to London, where they will be re-erected at the premises of Messrs. Lenygon and Co., in Old Burlington Street. The ceiling and panelling have been purchased by a well-known American. It has been represented to him that they ought not to leave this country, and he is quite willing to part with them on that understanding. Up to the present time it has not been decided to remove the windows and gables of the room, because the people of Banbury have expressed a wish that they should remain.

Another Big London Hotel.

Rumours of the building of a large hotel in Piccadilly on a site facing the Green Park have been circulated for some time past. The "Standard" now states definitely that such a building is to be erected by Mr. Frederick Sterrey, the chief hotel proprietor in New York. The work of clearing the site, which is at the bottom of the dip, and now occupied by six large houses and shops, will be commenced next month. It is stated that

the site will cost £1,000,000, and the building itself, which is to be of eight storeys and to contain nearly a thousand rooms, £600,000. Drawings will be submitted to the London County Council shortly.

Rembrandt and Meryon Etchings.

On Wednesday last, at Messrs. Sotheby's, some fine etchings from the collection of Sir Frederick Wedmore realised a total of £3,011. They included works by Rembrandt, Méryon, D. Y. Cameron, Muirhead Bone, and Whistler. "L'Abside de Notre Dame de Paris," by Méryon, second state, on thin ivory-white paper, was sold for £330, and "St. Etienne du Mont," first state, on green paper, £70.

The London Society.

A meeting of this society will be held tomorrow, Thursday, at the Royal Society of Arts, John Street, Adelphi, at 8.30 p.m., when there will be a debate on Mr. Raffles Davison's paper, "London as it is and as it might be." Colonel R. C. Hellard, C.B., will open the discussion by explaining the principles on which the recommendations as to the proposed new roads in the report of the Traffic Commission have been made.

Resignation of Sir Maurice Fitzmaurice.

At last week's meeting of the London County Council the resignation of Sir Maurice Fitzmaurice, chief engineer of the Council and county surveyor for the City of London, was accepted as from the end of the present year. It was reported that the resignation was proffered in order that Sir Maurice might commence private practice. He has held the position of chief engineer since January 1st, 1902, and has been responsible for, among other work, the construction of the Rotherhithe and Greenwich tunnels and the embankment of the new County Hall.

The Future of English Wall-Painting.

At a meeting held last week at Crosby Hall, under the auspices of the Society of Mural Decorators and of Painters in Tempera (Sir Charles Holroyd presiding), Professor Selwyn Image, speaking on the future of mural painting, said it would be difficult to imagine anything more likely to arouse the enthusiasm of art lovers than the movement connected with the exhibition of designs for mural painting now open at Crosby Hall. The social idea of art, he said, was spreading among us—that is, the idea that art is not a thing for the fortunate few, but for the whole community, through the decoration of our public buildings. So he would say to the critics, be generous to this movement; and to the students, be tremendously serious: do not treat wall-painting as a sort of bank-holiday lark. And as they are serious, so must they be simple in their methods. He would draw their attention to the astonishing simplicity of the beautiful old English wall-paintings, of which several copies are being shown in the exhibition (which closes on Saturday next).

OBITUARY.

Mr. J. Wright Clarke.

We regret to announce the death of Mr. J. Wright Clarke, of New Wandsworth. As instructor in plumbing at the Regent Street Polytechnic for a period of twenty-eight years, he was well known. He was also the author of numerous technical books, including several on plumbing and sanitary science, which are highly esteemed.

IN PARLIAMENT.

(By Our Press Gallery Representative.)

Piccadilly and Regent Street Buildings.

In the House of Commons, Mr. Soames asked the Secretary to the Treasury whether the building adjoining the Piccadilly Hotel on the east side, which had been set back, was on Crown land; and, if so, whether he was aware that a front was now being erected which, instead of completing the design of an eminent architect for the elevation to Piccadilly, was of a totally different character, completely discordant with the remainder of the block; whether drawings of this front were submitted to any Government department and approved by them; whether it was the original intention of the Government that, in the rebuilding of Regent Street Quadrant and the block of Piccadilly east of the hotel, there should be a similarity of treatment of the whole façade; and, if so, why that intention has been abandoned; and whether the Government in future will exercise sufficient control over the buildings erected on Crown land to prevent the recurrence of such an unhappy result.

Mr. Masterman said the building referred to stood on Crown land held under a lease granted before the hotel was commenced. The Commissioners of Woods had had prolonged negotiations with the various parties concerned, but they were advised that they had no power to prevent the re-erection of the old front. It was the intention that, in rebuilding the Quadrant, there should be similarity of treatment throughout, but objections had been raised to the original design by contending interests, and the question was now under consideration. No definite design was even settled for the buildings in Piccadilly east of Nos. 19 and 20. In normal cases the Commissioners had full power to control buildings erected on Crown lands. In this instance there was no new building, but only the re-erection of an old façade removed when part of the former premises were thrown into the street.

Mr. King asked if he was to conclude that the beautiful design was not to be carried through.

Mr. Masterman said he did not think that was to be concluded from his reply.

India's New Capital.

Mr. Montagu, the Under-Secretary for India, informed Mr. Wedgwood that the area now being considered for the purpose of the site of the new capital at Delhi formed part of the lands which were notified immediately after the announcement at the Coronation Durbar for acquisition under the Land Acquisition Act. In his Budget speech on March 25th, the Viceroy said that the cost of acquiring a space of thirty square miles embracing this site would not be more than £200,000 or £233,000.

New Building in Lincoln's Inn Fields.

Mr. Remnant asked Mr. Wedgwood Benn, as representing the First Commissioner of Works, if he could state whether the building now in course of erection adjoining the Land Registry in Lincoln's Inn Fields was being built for the Government; and, if so, under what Act and for what purpose was it intended.

Mr. Wedgwood Benn, in a printed reply, stated:—The answer to the first question is in the affirmative. The Act is 63 and 64 Vic., c. 19. Until the accommodation is required by the Land Registry, the greater part of the building will be occupied by the Land Valuation Department.

BELGIAN SCAFFOLDING PRACTICE.

BY A. G. H. THATCHER.

In building practice, there are doubtless many matters on which international interchange of ideas would be beneficial. Mr. Thatcher, who has rendered excellent service as a Government expert on scaffolding, shows in this account of Belgian scaffolding practice how largely Belgium has profited by the example of adjacent countries, and, inferentially, what we may miss by our insularity.

MOST countries in Western Europe are now to an extent cosmopolitan. Habits and conditions tend to uniformity, and methods likewise tend towards regularity. The geographical position of Belgium, surrounded as the country is by the more progressive nations, allows to a considerable extent the performances of the neighbouring nationalities to be reflected within its boundaries. It is therefore by no means strange that, as a rule, Belgian scaffolding has no particular characteristic of its own, but follows the methods usually adopted and seen in England, France, and Germany. Each of these national types is at times to be seen in Belgium, with such slight variations as local necessities demand, or local proclivities dictate.

In one particular, however, the Belgian builder adopts a distinctive line of his own, and this, curiously enough, is in the habit of foresight.

The Belgian builder seems to be the only representative of his class to realise and make provision for the certainty that a building will from time to time require to be repaired, and that repairs of any extent, even if it be only exterior painting, require scaffolding of some kind. This contingency our Belgian confrère anticipates by arranging, along the ex-

terior walls of the building, immediately under the cornice or eaves level, a series of openings in the brickwork. These are left as the erection of the building proceeds, and on completion they are covered with iron plates, sometimes quite plain but usually showing some slight attempt at ornamentation (see Fig. 1).

When repairs are required, it is quite a simple matter to remove these plates, insert needles, and suspend the scaffolding on them. Fig. 2—a sketch taken in Brussels—is a general illustration of the method. Fig. 3 is a section showing the framework in detail. No bracing is required, and the scaffolding is not supported from below, the mere force of gravity helping to keep it steady. The connections to the needles are made in two ways. The connection nearer the building is of cordage. This is done in order to prevent, by reason of the friction set up, any tendency on the part of the scaffolding to move from or towards the building in case the needle happens to be not quite level. The outer connection is simply an S-hook of iron (Fig. 4). The scantling used is of the slightest. At times light poles are split and fitted like ladder sides. The needles average 6 ft. to 8 ft. apart. To prevent the structures swinging outwards when the men are at work

on the lower stages, a spike is driven into the wall and a connection made to it. The workmen do not use ladders in order to get about. The platform is of one board only, and this enables the mechanics readily to use the footholds and climb from platform to platform.

Guard rails are regularly provided on

FIG. 5.

FIG. 11.

the outside; and, generally speaking, the whole arrangement answers its purpose well.

At times the design of the building prevents the use of needles. The same material for scaffolding can be adapted for erection on the ground, and serves usefully where the work to be performed does not necessitate the use of heavy materials (see Fig. 5).

The advantages of the system just described, as compared with the use of boats or cradles, are that there is less swaying in a wind, that the whole front of a building can be worked over at once, and that materials of an awkward nature to handle and fix, such as rainwater piping, can be successfully dealt with.

The system of suspending scaffolds is common in Italy; in fact, it is apparently a very old method, and one that was generally used in building the mediæval cathedrals.

Although the scaffolding just described is that which is most commonly employed in Belgium for effecting repairs, the cradle is also to be seen, although not to the same extent as in England, where the cradle scaffold has perhaps reached the greatest development yet attained, the methods arranged for its suspension being at times most ingenious. In Antwerp, however, an appliance for this purpose is in use which is particularly suitable for the work. Fig. 6 shows the appliance. A slate can be taken from the roof, and the quadrant pitched into the wall plate. Any turning movement is prevented by the T-piece which fits against the wall. The cradles are practically the same as the English, and are raised and lowered by blocks in the usual way.

Fig. 7 is a photograph from Antwerp showing an arrangement of trestle scaffolding. It is a good example of how not to do it although to some extent it follows the Scottish system. It is both blocked up and carries another trestle—two forbidden practices. The arrangement shown by Figs. 8-9 seems to be a good one, as reference to the drawings (p. 659) will show. The base is higher than is customary in

France, but the principle is the same. The members are firmly bolted together, and the rising standards are also bolted where shown to the required height.

Pole scaffolding is not a strong point with the Belgian builder. The general arrangement is after the English methods, but to our eyes very defective. Fig. 10 shows a pole scaffolding erected in Brussels. The poles are not always of the spruce species, but are of a growth having many more branches which in many instances are not lopped off closely, which may be an advantage in preventing cordage slipping. Putlogs are usually of short poles, and, to facilitate tying-in, are carried within the building wherever

FIG. 10.

possible. The standards are erected about 8 ft. apart, but the ledgers upon which the stiffness of a scaffold so much depends are laid just where a platform is wanted, and not at regular 5 ft. intervals. The bracing is slight, as will be seen by reference to the photo, where a brace is shown tied at its top end and middle only; its efficiency, which is demanded by the

FIG. 16.

extent of the whole erection, would have been much increased if the bottom end had been tied to a standard also. The cordage, too, is badly kept, and the knots are made in a way that would make an English scaffolder blush. It is true that cleats are at times placed to carry an excessive stress, but this procedure is not general. In fact, the pole scaffolding in Belgium does not excite admiration.

A different opinion must be given, however, of plank and timber erections. These, following the lines of the French and of our own gabbard methods, are substantial, and are built on really scientific lines. They can be carried to great heights, as will be seen by the view (Fig. 11), which shows the west end of a Brussels church recently erected. The spire is shown finished, and its scaffolding taken down; but what remains is a perfect maze of substantial and accurate workmanship.

FIG. 7.

Each bay between standards and ledgers is singly braced. Proper stairways are built for an easy ascent, and guard rails are fixed to all working platforms. It is really difficult to see in what way such a scaffold could be improved upon. It is an object-lesson to English builders, with their fondness for the pole, to show what can be done with planks and bolts. As might only be expected, the general details of erection follow the French system rather than the Scottish. Figs. 12 and 13 (p. 659) show a corner standard and ledger, the scantlings being according to the weight the scaffold has to carry. The standards—about 9 in. by 3-in. planks—are used in threes to complete a 9-in. by 9-in. post, and the ledgers are about 9 in. by 3 in., used in pairs, one on each side of the standard. It will be remembered that in the gabbard system the ledgers are used singly, and by proper fitting are arranged to project through the standard—an easy method, as the posts are built up in lengths. Of course the gabbard ledger gets, in this way, an absolutely strong support, and is not dependent upon the strength of the bolts as in the Belgian system, although in this case cleats are used where necessary to secure additional strength.

Lighter scaffolding of the same type is shown by Figs. 15 and 16. These are for repairing purposes only, but may be expected to stand for some time. A front view of four bays is shown by Fig. 17. Fig. 18 shows the method of jointing between continuous planks. Fig. 19 is an illustration of a small timber tower seen in the larger churches and cathedrals for interior repairs. It can be easily taken apart and re-erected. It is not adjustable as to height, except by adding or dismantling the higher floors, and in this respect is inferior to similar structures in use with us, which can be wound up and down.

Viewed as a whole, Belgian scaffolding may be taken to be extremely practical, and quite on scientific lines. It excels the French in the care with which it is built; it has nothing of the light and dangerous appearance of the Italian; and has the ad-

FIG. 15.

FIG. 20.

BELGIAN SCAFFOLDING.

FIG. 19.

vantage of being more up to date than the English. It accords, perhaps, most completely with German methods.

As may be inferred from one or two figures in the photographs, the Belgian artisan falls into line with most Continental mechanics in the wearing of overalls. It is a cleanly habit, and one to be commended.

The last photo, Fig. 20, shows the common Belgian brick cart. Being built low, it is easily filled and emptied. Others approximating to English carts are to be seen, but are higher on the axle, and are in many respects quite different from the one shown here.

New Fellows and Associates of the R.I.B.A.

The following have been elected Fellows of the Royal Institute of British Architects: E. G. Allen, W. Pott, H. P. Roberts. The following, having passed the Final Examination, have been elected Associates: H. H. Archer (Southport), H. J. L. Barefoot, R. J. K. Harris (Sydney, N.S.W.), J. B. Healing (Leicester), P. D. Hepworth, C. H. Lay (Saxmundham), R. D. Nicol (Calcutta), G. Owen (Warrington), R. Shears, W. B. Stedman (Margate), R. Stockton (Stockport), and C. Voysey.

PARIS JOTTINGS.

M. Pray Retires.

The new architect-in-chief of the Prefecture of Police is M. Alphonse Jacques Gargué, who, in July, will supersede M. Pray, who retires with the title of honorary architect-in-chief—an example of the pleasant little forms of politeness in which the French excel.

A Paris Museum of Hygiene.

The Museum of Hygiene of the City of Paris, which has been established and equipped by MM. Juillerat and Leroux, has been opened permanently at 57, Boulevard Sébastopol. It should help very considerably the sanitary movement of which Parisians have evidently become conscious.

Motion Study: and an Innuendo.

Mr. F. B. Gilbreth's book on motion-study as applied to the building trade is attracting attention in Paris. Mr. Gilbreth claims that by reducing to five, or fewer, the eighteen movements formerly made in laying a brick, the number of bricks that a man can lay in an hour has been increased from 120 to 350. Commenting on this, "Le Bâtiment" says that in Paris a bricklayer and his labourer lay, normally, 620 bricks in nine hours. "By the American method, the same work could be done in two hours. Is this true? or is it merely—American?"

Workmen's Compensation.

The Parliamentary commission charged with enquiry into proposals for modifying the law of 1898 with respect to accidents has presented its report. The recommendations have reference to medical witnesses, to the period of compensation, which is extended to three years, and to the extension of legal assistance to the procedure of appeal. M. Defontaine, who drew up the report, has been invited to confer with the Labour Minister (M. Viviani) with respect to the resolutions which have been adopted by the commission.

Beaux-Arts Awards.

The jury of the Three Arts competition of the Ecole des Beaux-Arts has issued the following awards in the architectural section: First Class (Design): 2nd medals to MM. Petit and Potier (Deglane); Forest (Dufresne and Recoura). (Modelling): M. Grapin (Bernier). Second Class (Design): 3rd medal: M. Chandler (Laloux). (Modelling): 3rd medal: M. Chapman (Duquesne and Recoura). (Ornamental Design): 3rd medal: MM. Bocage (Laloux); Boschnakian (Bernier); Féray (Umbdentock). It is good to see the Saxon-looking names in the list, even though one feels instinctively that they probably belong to Americans.

Apprenticeship Proposals in the Senate.

MM. Henri Michel et Mascaraud have placed before the French Senate some proposals, based upon the opinions of various organisations of employers and employed, relative to the question of apprenticeship. A digest of these ascertained views resolves itself into the following series of proposals: (a) As an essential condition of apprenticeship, there must be a binding contract or indenture between the parties. (b) Surveillance of apprenticeship. (c) Theoretical and practical examination of apprentices and issue of certificates of competency. (d) Limitation of the number of apprentices engaged by any particular employer, and power of the authorities to withhold from any particular em-

ployer, temporarily or perpetually, the right to employ apprentices. Surveillance is held to be necessary as much in the interest of the employer as of the apprentice, and this duty will be confided to special committees, local and departmental. On the expiration of the indentures, the apprentice must submit to examination, and the examiners will report both on his proficiency and on the character of the instruction given by the employer. The special committees will have power to consider and decide upon any complaint that in any specified instance the number of apprentices is excessive; and in case of any grave abuse, the special committees are to prevent the offending employer from taking apprentices. A conference on apprenticeship, with particular reference to the building industry, is to be held in Paris on July 5th, the occasion being an exhibition of the work of the students of the technical schools pertaining to this special group of trades.

Cheap Dwellings Competition.

The twenty-first annual competition of the Société Nationale des Architectes has for its subject this year "A cheap dwelling for a numerous family" ("La maison d'habitation à bon marché pour famille nombreuse"). Two types of dwellings are specified—the tenement dwelling (maison collective) suitable for working-class districts in towns; and the separate dwelling (maison particulière) situated outside the great centres of population. The designs are to be delivered on September 10th. The competition is open to architects and to architectural students between the ages of eighteen and twenty-five.

Bogus Accident Claims.

It has been long known that in France the gentle art of malingering has been organised as an established system of extortion. Four years ago, M. Villemin, president of the Syndicat Général de Garantie du Bâtiment et des Travaux Publics, published charges of fraudulent malingering against certain excavators, and roundly accused certain medical men of aiding and abetting them. Thereupon the doctors threatened M. Villemin with an action for defamation, and ultimately the matter was investigated by the First Chamber of the Civil Tribunal. The president of the chamber, M. Monier, has now delivered his judgment. He finds that during 1907 and 1908 very numerous cases were reported of workmen simulating injury from accident and being supported in their fraudulent claims with oral evidence or written certificates by medical men; and that in exposing these frauds M. Villemin was acting in the interests of justice and the common good. The tribunal therefore finds that there is no ground of action against him.

A MOGUL MARBLE SCREEN
FROM DELHI.

At a time when Delhi and Indian architecture are attracting so much attention at home and abroad, it will be of interest to see the notable example of Mogul architecture shown on p. 648, which has been kindly sent to us by Mr. R. B. Thompson, of Messrs. R. M. Thompson and Son, architects and engineers, Mussoorie. The screen, in which the scales of Justice are the dominant feature, is in the Dewan-i-Khas (Hall of Private Audience, Delhi). The marble, though carved with the intricacy of lacework, is not so fragile as it looks, being more than 1½ in. thick. Of course, things of this description cannot be

produced with equal facility nowadays, when it is no longer possible to obtain supplies of marble without payment, nor to have the work done by *begars* (pressed labour).

THE TEAK TRADE AND THE
"TUSKER."

Probably no business in the world is more absolutely dependent on the services of an animal than is the teak industry on those of the elephant. In Java, it is true, says a writer in the "Times," the timber being smaller and the conditions different, hand labour and implements are employed, and in parts even of Burma and Siam the country is sufficiently flat to permit of carting by buffaloes being used as a method of extraction. But these parts are comparatively few and far between, and the obstacles in the way of introducing heavy plant into a country deficient in good roads, bridges, or facilities for transport, must be at once apparent. Even without these obstacles it is very doubtful whether teak, being so scattered as it is, could ever be profitably worked up and down steep hill-sides by machinery, while it is as certain as anything can be that no machinery could ever be devised to perform the part played by elephants in the water. Apart from the enormous bodily strength which enables it to drag, an elephant can with its forehead, trunk, or tusks push and roll enormous logs about as if they were play-things, nor does it mind working in water 5 ft. and even more in depth.

Given shade, abundance of water, and good grazing, an elephant has a fair chance of keeping its condition throughout the seven months which constitute its working season. The latter begins in June. From that time onward the animal's daily and weekly routine is something as follows: Directly it is daylight the rider leaves his camp, goes out to track his charge, which, despite his hobbled condition, will often succeed in straying a distance of some miles, bathes him all over in the creek—this is one of the most important of a mahout's duties—and brings him to the scene of the day's work. Operations commence at 7 a.m. or a little before, and go on till 11, by which hour the power of the sun generally renders it imprudent to continue further. For it must be remembered that the elephant is naturally a nocturnal animal, and extremely liable to sunstroke. On the completion of their day's work the animals are brought to the camp, divested of their gear, hobbled, and turned out into the jungle. After five days' work they receive two days' complete rest, or three days if the spell has been an arduous one. In January, or early February, they are removed to evergreen forests, where they will, even during the ensuing hot months, be able to find abundant food and water, and being called upon to do no work whatever soon become fat and ready for a new season's labours.

The elephant, despite its great strength, is a very delicate animal, and easily dies from one or another of a number of causes, from which, despite all their precautions, the teak companies of Siam must reckon annually to lose between 5 and 10 per cent. of their stock. The increasing scarcity, and consequently increasing value, of elephants is indeed already a matter of grave concern to all interested in the teak business. Whereas ten or fifteen years ago a good "tusker" might be purchased for 2,000 rupees, three times that sum is now sometimes demanded, while cows and "hines"—i.e., tuskless males—vary in price from 3,000 to 5,000 rupees.

THE WASTE OF PUBLIC WATER
SUPPLIES.*

BY W. WHITEHOUSE, M.S.E.

What is Pure Water?

When we speak of "pure water" we mean "wholesome water." Sir William Crookes has stated: "There is a great deal said about microbes, and a good deal of nonsense talked. When we hear that every glass of water we drink contains microbes by the thousand it is rather a shock. If we had too pure water, too much sterilised, we should all starve. A friend of his tried to bring his children up on hygienic principles, and had everything sterilised. The poor children were nearly starved, and at last they were given good wholesome water, with plenty of microbes in it, and they got as fat as possible."

Clark's tables give the average quantity of water required by an adult as follows:—

- 2 pints for drinking, in addition to about 2 pints retained in his food.
- 3 quarts for preparing and cooking his food.
- 1 gallon for cleansing dishes and food utensils.
- 2 gallons for house cleansing.
- 3 gallons for washing clothes.
- 5 gallons for cleansing the body.
- 5 gallons as a proportion, assuming a plunge bath is taken once a week.
- 6 gallons for w.c. use.

Total 23 gallons, being the average amount — of water required daily for each individual.

Misuse and Waste.

The author considers the theoretical quantity given above is too lavish, although it is much less than the Romans used in ancient times. Professor Rideal informs us that "ancient Rome, with its nine aqueducts, served its people with 300 gallons a day per head, including the supply for the public fountains, baths, circus, and amphitheatre, and for sanitary and trade purposes. A special State department administered the supply, and, as a result of these efforts, classic Rome was far more healthy than the modern city."

All will agree that this example could not be followed in these days, as there are very few waterworks that could stand the strain.

It seems that a warning to the public is necessary to prevent waste or misuse of such an increasingly valuable commodity as pure water. The tendency of everyone who designs or manufactures water fittings and sanitary appliances is to rely upon an excessive supply of water, but they should be designed in such a way that the utmost efficiency and economy is obtained from moderate quantities, rather than by the waste of large quantities. An ordinary plunge bath holds from 30 to 70 gallons of water, and if everybody had a bath every morning, using, say, an average of 50 gallons each, there would be very few waterworks in the country that would be able to stand it. What is wanted is a greater use of the portable hip bath, with about three gallons of water, or some development of the shower bath by which a person could have a complete bath with a small expenditure of water, and so fulfil the ideal of the sanitarian, that every healthy person should have a head-to-foot bath once a day.

A very general idea prevails among water consumers that waste, although bad for the waterworks, is good for the drains and

sewers, but that is not true, because if the waste is due to defective fittings, it goes on in the daytime, plus the consumption, which in itself is, or ought to be, enough for all purposes. During the night, when the leakage is going on as before, and the consumption is small, the water is so distributed over a large area that it is of no use whatever as a flush to the drains and sewers, but is simply a waste of water, which could be more effectively used in a legitimate manner.

Causes of Waste.

There are various causes of the waste of public water. One is a misapprehension—as noted above—that a continual small stream of water along house drains improves the sanitary condition of the house. This is a mistake. A short sudden rush at intervals has a beneficial effect in flushing drains, but a continual dribble has none. There is no use, therefore, in allowing small streams of water to flow continually down water-closets, or other sanitary appliances. By improvements in the form of water-closets and of flushing apparatus, the former have been made quite self-cleansing with a flush of two gallons, or even of less, appliances being insisted upon that make it impossible to give a greater flush.

However, it must be admitted that by far the greater part of the waste that takes place is due to carelessness on the part of the consumers of water—often carelessness that can only be considered as culpable, if it be borne in mind that wilful waste of water supplied by waterworks is simply stealing. The water is actually public property if the works belong to a corporation or council, as the case may be; and even if they belong to a company the water is public property in the sense that the price which each individual has to pay to the company must in great part depend on the consumption of the whole, including waste.

Leaky Taps.

Although not generally the case, many householders are indifferent to the waste of water; it is therefore a matter of indifference to them whether, for example, a tap is running the whole night or not. Where the cost of leathering a tap is charged to the consumer, there are some who consider that it is to their advantage to allow the leakage to continue. In the works under my control—although the average consumption is low—we lose every night, between the hours of 12 p.m. and 6 a.m., from 15,000 to 20,000 gallons of water. The major portion of this quantity must be waste.

Apart, however, from this, a great deal of leakage takes place simply because it is difficult to appreciate how large a quantity of water is lost on account of an apparently very small leakage continuing through the whole twenty-four hours. It would astonish most people who see water merely dripping from a tap, or from a leaky pipe, to be told that the loss is likely to be 3 or 4 cub. ft. in twenty-four hours, or fully the average consumption of water of one individual. Yet if a measuring glass be taken it will be found that from 2 oz. to 3 oz. per minute of water may fall merely in the form of drops, and this corresponds to a large consumption in twenty-four hours for one person. It needs but a very small dribble to discharge 20 cub. ft. of water in twenty-four hours, or say, the quantity that ought to be consumed by an average household.

Prevention of Misuse and Waste.

The question of waste prevention has always been a source of trouble, and one of anxious consideration for the engineer.

Burton, in his treatise on water supplies, writes as follows: "Of late years large reductions in the consumption of water per head have been made by careful arrangements for saving waste. Waste has been saved in several ways; for example: (1) by the use of district meters; (2) by the use of house meters; and (3) by insistence on the use of house fittings of good quality only, and on their frequent inspection. I may say concerning the third item, that the difficulty in preventing waste in waterworks has seldom been felt to any great extent in connection with the street mains, or the larger appliances belonging directly to the proprietors of the waterworks. These are fixed under the charge of skilled engineers, and are under their supervision afterwards. It thus occurs that leakage is not very likely to occur in them, and that if it does it is soon stopped. In the case of house fittings it is quite different. These are put in by the builder or the householder, who employs whomsoever he likes; it is not in the least to the advantage of the former of these to be sure that no water waste takes place, and it is to the reverse of the interest of the latter to prevent leakage, because he has nothing to pay for leakage, while he has to pay for preventing it. Very stringent regulations have been introduced in most English and many Continental towns for the prevention of waste in houses, and these have been put efficiently in force in a considerable number of cases."

Notwithstanding the severe climatic changes in England, few precautions are taken against the grave inconvenience of waste occasioned by frost. House pipes are often left unprotected, and so placed that a burst will cause considerable damage. Cisterns are frequently situated outside, and when they freeze solid are the cause of serious annoyance. The pipes and fittings in the ground should always be laid a good depth, and all exposed pipes and fittings should be protected with some non-conducting material.

Waste-Water Meters.

The Deacon waste-water meter is familiar. There is no doubt about its excellency in the discovery of waste, as one meter will control a large part of a district, but there are many authorities who would hesitate to instal this system—in consequence of its cost and manipulation. It has even been suggested that every house should be supplied by meter just in the same way that it is supplied by gas. That is an exceedingly expensive way of controlling the supply on a large scale, and leads to the other extreme of undesirable parsimony in the use of water. To instal the meter system in my own district would cost £5,000, the cost of maintenance and inspection would necessarily be higher, which would mean raising the price of the water *pro rata*, as consumption was large or small, to cover the extra cost of maintenance.

Leathering Taps.

Quite recently a surveyor informed the author that the waste of water in his district was so large as to be quite absurd. It has never been the custom of his authority to leather taps, but some time ago he made an inspection of his district, and with some assistance leathered, or saw to the leathering of, the taps himself. In one month, he tells me, he saved by these means no fewer than 400,000 gallons. Assuming it cost 6d. per 1,000 gallons to pump and distribute the water, the saving is quite equal to paying the wages of two men permanently employed, apart from the saving to the consumer's fittings, and also

*Extracts from a paper read at a Western District meeting of the Institution of Municipal Engineers, June 20.

the saving of this precious and absolutely necessary fluid.

Speaking of the works under his own control, the author was pleased to say that it had always been the custom to leather and repair consumers' service taps, etc., and to fix new taps free of charge (excepting the cost of the tap). The result has been highly economical and satisfactory. The average consumption, excepting periods of continued drought, does not exceed 12 gallons a head per day, including that used for trade purposes, and they supply a population of 10,000.

These methods have enabled the water-works to keep in touch with, and to gain the confidence of, the consumers; the reporting of leakages is encouraged; and it has had the effect of making each and all of them an inspector, as it were. Leakages are promptly reported, and if they are not promptly attended to, of course there is a row. Notwithstanding the result, there are some who disagree with these methods, but no one can dispute that the system means convenience, advantage, and even privilege to consumers, and it is undoubtedly a joint means of preventing waste.

Checking Waste.

In conclusion, the author summarised a few things which would certainly have the result of checking waste:—

(1) *Night Inspection.*—This need only be periodical, but it would be the means of discovering underground leakages, as well as other causes of waste. The method to adopt would be for the inspector to proceed round the district during the night with a sounding rod, and to hand over the result of his discoveries to the fitters for further inquiry into the matter the next morning. This would have the effect of finding out wilful waste as well as that due to defective fittings.

(2) First-class fittings of approved construction should be rigidly insisted upon, as well as the laying and fixing of pipes for protection against frost.

(3) The enforcement of 2-gallon closet flushing cisterns, and automatic flushing cisterns of stated capacity for urinals. Great economy in the use of water could be effected if it were possible to provide a satisfactory and water-saving substitute for the plunge bath.

(4) Outside closets could be an approved make of the waste-water type.

(5) Public inspection and repair of draw-off apparatus, such as leathering, etc., free of charge.

(6) Covered reservoirs for spring water to obviate the waste caused by the necessity of cleansing of algæ, or water weed, which rapidly forms in hot weather. (This advice may be somewhat superfluous, as spring water reservoirs are very rarely left uncovered nowadays.)

(7) Plenty of air valves and sluice valves to prevent the emptying of long lengths of main when repairing or tapping.

(8) Apparatus for tapping mains under pressure, and so save emptying them when doing this work.

(9) Pressure reducing valves in very hilly districts, wherever possible to fix them.

Inspection in New York.

Supplementing the advocacy of inspection in the above paper, it is interesting to note that water waste prevention in New York has been carried on by the inspection method during the past year or more, and its results, as described in the annual report of Commissioner Thompson, of the Department of Water Supply, Gas, and Electricity, show that where carelessness exists in using water the system can ac-

complish much good. The work has resulted in reducing the average daily consumption from 540,000,000 gallons to 480,000,000 gallons. Two methods have been followed. Along the water front, districts have been isolated one at a time and investigated by the pitometer method, and some heavy leakages have been detected in this way. One of them, an underground leak at the Battery, is estimated to have been discharging 880,000 gallons daily into the harbour for many years, an amount of water worth over \$42,000 annually at meter rates. The second method of checking waste has been a house-to-house inspection. In a little more than two months 97,245 buildings were visited. Second inspections were made in many cases to ascertain whether repairs had been made as directed. Both methods of checking waste have cost about \$30,000, and the water saved by them is estimated to be worth about \$2,000,000 a year. The main value of the work has been in conserving the supply until the Catskill works are finished, and for this purpose it has unquestionably proved efficient and cheap. But it is not a complete substitute for a universal meter system, and the records of the house-to-house inspection show this. Out of 55,371 buildings examined during the first inspection, 36,431 were found to contain 158,363 leaking fixtures; on a second inspection of 41,874 buildings, leaks were still discovered in 14,000 of them. This shows that even when it was known that a failure to repair leaks would mean

a fine in addition to the expense of repairs a large number of people failed to have the work done. When the danger of re-inspection has passed, the old conditions will undoubtedly become established again. The carelessness which permits waste will develop, and the same people who are watchful about unnecessary use of gas and electricity, because both are bought by meter, will look upon water as something as free as air. Commenting upon this report, the "Engineering Record" remarks that meters ought to be installed, not only that the city may demand payment for the exact amount of water taken by each consumer, so that all are treated alike, but also that the day may be far removed when additional expensive works for increasing the supply become needed.

OUR PLATE.

The New Quadrangle, Merton College, Oxford.

The new quadrangle of Merton College, Oxford, occupies the site of Alban Hall, which some years ago was annexed to Merton College. In forming the quadrangle, the only portion of the Hall which could be retained was part of the front on Merton Street. This, however, has been considerably modified as regards the attic storey, which had been rebuilt not very long ago.

The general idea was to construct a three-sided quadrangle, open to the south

Supplement to THE ARCHITECTS' AND BUILDERS' JOURNAL, Wednesday, June 26th, 1912.

BUILDINGS IN NEW QUADRANGLE, MERTON COLLEGE

...E, OXFORD. BASIL CHAMPNEYS, B.A., ARCHITECT.

on to the Fellows' Garden, from which it is divided by an ornamental iron railing.

The new quadrangle contains, besides a number of rooms for undergraduates, a set of rooms for a Fellow, a junior common-room, and, in the basement, baths and sanitary fittings.

The material used is Weldon stone, with Clipsham in the positions that are most exposed to the weather. The architect is Mr. Basil Champneys, B.A., and, as a matter of individual judgment, we venture to think that it is his *opus magnum*, or that, at all events, among the many fine works whose merits have been collectively recognised in the bestowal upon Mr. Champneys of the Royal Gold Medal of the Institute this year, he has done nothing better, although we are not forgetting his authorship of many other collegiate buildings at Cambridge as well as at Oxford, and of the Rylands Library at Manchester. The Royal Gold Medal, by the way, was presented to Mr. Champneys on Monday last. A portrait of the new medallist, and some particulars of his career, appeared in our issue of March 6th of the current year. The builder was Mr. G. W. Simpson.

BOOK NOTICES.

Farm Buildings.

Although, at the very outset, we are warned very ingenuously that "this small volume is addressed to landowners, their agents, and tenants, and not primarily to architects and builders," it is perfectly obvious that it is this very fact which constitutes the value of the book to the architect and the builder, neither of whom desires, from such a source, instruction in his own business, but both of whom, supposing that they have this class of work to do, or a prospect that they may some day possibly have to undertake it, will be glad of intelligent information from the agricultural standpoint. The client, it is true, nearly always thinks he knows what he wants, but his fallibility is signalled by the appearance of this book; and, of course, it is impossible that, knowing, as a rule, little about any estate or condition other than his own, he can be in a position to generalise circumstances, evolve principles, and apply them in accordance with the most economical methods. Having a far larger experience of what has been done, the author is well equipped to impart information—to assume the rôle of teacher which in his preface he modestly disclaims, and it therefore seems very probable that architects may derive direct as well as indirect advantage from his knowledgeable discussion of the data. It is evident that he knows not only the requirements, but various ways of meeting them, and he is usually able to put forward excellent reasons for preferring one system to another, in site, planning, construction, or sanitation.

The style and substance of the book may be not unfairly inferred from a single short extract: "To enable the architect or clerk of works to prepare the necessary plans, the live stock, dead stock, and barn accommodation, together with every appliance to make such effective, must be determined. This will, of course, depend upon the nature of the holding, and the course of husbandry pursued upon it. The first point, and one difficult to determine, is the maximum of live stock which the area will support; and for this, maximum provision should be made." To prepare anything less than this is to render necessary an

annex from time to time, and so mar the original design."

Farming economy, and the philosophy of farming, naturally take up a great deal of the author's attention, but the disquisitions always bear some more or less close relation to buildings, "which are to the land, which is the raw material, what a factory is to cotton, linen, and the like." Practical hints, however, as distinguished from mere theorising, abound; and the score or more of illustrations, which have been mostly drawn by the author, are distinctly utilitarian. The frontispiece, apparently reproduced from a painting, shows a delightful old English barn, but otherwise art is left to the architect.

Farm Buildings for Landowners, Agents, and Tenants. By Charles Edward Curtis. London: Vinton & Company, Ltd., 8, Bream's Buildings, Chancery Lane, E.C. Pp. viii. + 144, 7½ ins. by 5 ins., price 3s. 6d. net.

Municipal Engineering Problems.

We cannot see that the title of "Problems in Engineering" is at all well chosen. The popular conception, or misconception, of the term "engineering" is that it refers specifically, if not exclusively, to the making of machinery—is a matter of the shaping and fitting of iron and steel. No matter how erroneous this view may be, it is general and effectual; and therefore the title of this book is likely to be generally misunderstood. The mechanical engineer who bought it on the strength of its title would be disappointed, and, on the other hand, the civil engineer, or municipal engineer, or surveyor, might hesitate to infer from its title that the book was primarily intended for him, as on examination it appears to be. The ten sections into which the book is divided deal respectively with mechanics and hydrostatics, strength and elasticity of materials, theory of structures, surveying and levelling, water supply and hydraulics, sewerage, sewage disposal, road-making and tramways, building construction and materials, and the last section is headed "Law and Miscellaneous." Under each heading are grouped vital questions, which collectively represent a fairly complete survey of the subject; and these "problems," tersely stated, are worked out with clearness and brevity, with the aid of diagrams whenever these appear to be necessary. Instruction by question and answer is the most natural method of imparting knowledge to students, for whom this manual is obviously intended; and the book contains a vast amount of information, the very many points in which ought to have been rendered more easily accessible by means of an index.

Problems in Engineering, with Solutions. Being Questions and Answers Reprinted from the Assistants and Students' Section of the "Surveyor and Municipal and County Engineer." First Series, 1909-10. Women Invade the Building Trades.

The president of the New York Association of Building Trade Employers announces that in October next a school will be opened in which women will be taught the trades of plumber, carpenter, mason, etc. Thirty-six students have already entered. Hitherto the incursions of ladies into the building trades seem to have been somewhat irregular. The case of "Charlie" may be remembered. "Charlie" was a lady who, disguised as a man, worked for years as a paperhanger. A more recent case is that of a young lady who, dressed in male attire, held a job as a plumber's mate—a position to which many girls may legitimately aspire without necessarily working at the trade.

THE SCIENCE MUSEUM: NEW BUILDING SCHEME.

The final report has been issued of the Departmental Committee appointed to advise as to the present condition and future development of the valuable collections comprised in the Science Museum at South Kensington, and the Geological Museum in Jermyn Street. The precise boundaries of the site available at South Kensington have been determined, and hence the Committee are now able to report upon the adaptation of the general plan of the new buildings to the requirements of classification and exhibition of the collections.

By arrangement with the Trustees of the British Museum, the building for the Museum of Practical Geology and the offices and library of the Geological Survey is to be placed on part of the site allotted to the Natural History Museum, and accordingly the whole of the Science Museum site will be available for the immediate and future needs of the last-mentioned institution. The site extends from Exhibition Road to Queen's Gate, a distance of 1,150 ft. For a considerable part of its length at the east end it has an effective breadth of 190 ft., and at the west end it is 170 ft. broad; the intervening portion has a breadth of 100 ft. The two end portions afford suitable ground for a combination of large halls with surrounding galleries, which would at once make full use of the space and form suitable accommodation for exhibiting the collections effectively.

An examination of the intervening and narrower portion of the site, in relation to the buildings to the north and south of it, shows that the central part may well be occupied completely by lofty buildings, such as would be required to enclose a hall worthy of its place in the centre of the Museum. The sections connecting the central block with the east and west blocks, however, ought to be comparatively low along their north side. Even so, these may be occupied on their south side by ranges of side-lit galleries carried to the same height as the main building, and broad enough to give a total internal breadth of 70 ft. Thus the scheme may provide for continuous exhibition hall and galleries along four floors.

It is estimated that the floor space required for the immediate needs of the Museum is 265,000 sq. ft. The complete scheme of buildings will provide a total space for the exhibition of collections of 377,000 sq. ft., so that the margin for expansion is 42 per cent. The corresponding excesses to meet ultimate requirements under other heads of accommodation are on a still more liberal scale.

In the Committee's opinion the building scheme for the complete occupation of the site might conveniently be carried out in three sections, and they recommend that these should be put in hand in succession, beginning with the eastern block. In the eastern end of the buildings now on the site there is only a relatively small part of the collections, and for this part it would not be very difficult to find temporary accommodation. The erection of the new buildings in the order suggested would thus entail a minimum of disturbance in the ordinary work of the Museum. The new eastern block when completed would suffice for the accommodation of all the collections now in the "Southern Galleries," so that these galleries might in turn be demolished to make room for the central block of the new buildings without requiring any serious interruption, either in the

exhibition or in the current development of the collections.

It is suggested that it would be well to delay final consideration of the central and western blocks till the eastern block has been occupied, so that action may be taken in the light of experience of work under new conditions.

POPLAR'S ELECTRICITY WORKS EXTENSIONS.

In order to supply the increased demand for electrical energy in the Poplar district, which has risen from 1,379,620 units at the end of March, 1906, to 7,378,839 units at the corresponding period of this year, some important extensions of plant are now being carried out by the borough electricity department. The area of the borough is approximately five miles long by one mile wide, and the system of supply adopted is alternating current at 6,600 volts and 50 periods at the generating station at Bromley-by-Bow, which is fed direct to substations in Millwall, Blackwall, and Old Ford, where it is converted to 460 volts direct current.

The maximum power demand during last winter was 4,500 kw., an increase of 820 kw. over the previous year.

In order to avoid waste of capital in small extensions two 3,000 kw. Willans and Robinson combined impulse and reaction turbines coupled to General Electric three-phase alternators are now in course of erection, the guaranteed efficiency of which, over three-quarter, full, and overload, is 13.55 lb. steam (average) per kw. hour. The switchboard is of remote control type, and is being erected by the British Westinghouse Company. Two Babcock and Wilcox watertube boilers of 41,600 lb. an hour maximum evaporative capacity are being installed in the initial stage of the extensions, and it is proposed to install a further pair of this size and type as the load increases.

The plant is housed in an entirely new building of solid steel framework, filled in with brickwork, which has been erected alongside the present works and provided with a Royce overhead travelling crane of thirty tons capacity. There is no chimney shaft, as each boiler is fitted with a separate steel uptake.

The lay-out of the plant has been designed by the borough electrical engineer, Mr. J. Horace Bowden, and the total cost is under £10 per kw. installed.

STATE BRICKWORKS.

A Government brick plant for supplying the Department of Public Works, New South Wales, was placed in operation in April, 1911, to produce bricks more cheaply than it was possible to buy in the open market. About 36,000,000 bricks are required annually for State purposes, and it is estimated that the manufacture of bricks by the Government will effect a saving of 50 per cent. over the prices asked by local makers. It is stated that the surplus output from the Government kilns will be made available for sale to the general public at reasonable rates. In addition to ordinary clay or shale brick, sand-lime bricks are to be manufactured. For this work the Department is burning its own lime. It is difficult to share the optimism about results. The United States Government Printing Office has a history that should make anticipation less sanguine, and the London County Council's little adventure in brick-making at Norbury simply killed the notion so far as our own country is concerned.

THE HOUSING OF THE WORKING CLASSES BILL.

The Standing Committee of the House of Commons, presided over by Mr. Eugene Wason, continued the consideration of the Housing of the Working Classes Bill last week. Mr. King proposed a new clause providing that, for the purpose of assessing compensation or of valuing land to be acquired for the provision of dwellings for the working classes, the arbitrator, court, or valuer should base his award and fix the valuation upon the total value of the property as valued for the purposes of the Finance Act, 1910, and upon any subsequent or consequent valuations made under it, and should add such allowance for disturbance as was proved equitable. He said the uncertainty as to the valuation or compensation to be paid for land had proved a great drawback to the promotion of housing schemes by local authorities.

Mr. Hills agreed that the cost of land had interfered with housing schemes, but contended that this proposal, instead of giving the slum owner smaller compensation because of overcrowding, would give him far more than the Bill at present did. The total value under the Finance Act meant the selling value in the market, which obviously was enhanced by overcrowding.

Mr. J. Samuel, from the Ministerial side, and Sir Arthur Boscawen both urged that the clause would hamper the working of housing schemes. The latter said that by the proposal the local authority would, forty or fifty years hence, have to pay more for large houses which had degenerated into slums than their present value.

Mr. Booth, who supported the clause, said he personally surveyed 100 houses in Soho at the time of the formation of the London County Council, and found that houses which were formerly gentlemen's residences at £100 a year were as tenements making from £200 to £250 a year.

Mr. Burns (President of the Local Government Board) said no one defended the present method of acquiring land for housing. The cost often prohibited housing reform. The Government would support Mr. King's proposal. They were not only in favour of preventing the slum owner in the centre of the town from obtaining excessive compensation—and Clause 9 of the Bill restricted it to more reasonable proportions—but they believed that the housing schemes of the future were more likely to be undertaken on the outer areas of towns. Prices of from £400 to £600 an acre in these semi-rural areas were prohibitive for the erection of cottages costing £150 or £200, and the clause would place the rural or semi-rural landlord in the same position as regarded the payment of excessive compensation as the promoters of the Bill had insisted upon for the slum owner in the heart of a city. What was needed was some means by which land in either area could be obtained for housing at more reasonable prices.

Lord A. Thynne contended that, whilst the Committee rightly penalised the slum owner, when land was required from other owners they ought to trust to the ordinary process. Mr. Charles Bathurst also argued that the only equitable way both for owners and ratepayers was to take the fair market value of the land for the time being.

Sir A. Boscawen said the Committee were taking a leap in the dark, and no one knew what the effect of it would be.

The clause was added to the Bill by 25 votes to 21. A Government amendment

enabling one inhabitant householder, instead of four, to make an appeal to the Local Government Board wherever there was a deficiency of housing accommodation was agreed to, and the Bill then passed through Committee.

NEW YORK'S NEW BUILDING CODE.

The joint committee of specialists in building design and construction who have been studying for more than a year and a half the proper provisions for a building code for New York City have submitted their draft to the Board of Aldermen. The names of this Committee, representing the architectural, contracting, engineering, underwriting and official interests, are said to carry the weight of authority with them. Fortunately there is no likelihood of any attempt being made to rush this proposed code through the Board of Aldermen, and consequently it should have the benefit of painstaking and exhaustive discussion.

It is described as a compromise between the divergent views of specialists, reached after careful and prolonged consideration and consultation with architectural, engineering, and business firms particularly interested in the individual sections of the proposed requirements. As in every compromise, there are features which are open to criticism; Mr. Ernest Flagg, the eminent architect, has made a number of such criticisms, several of them of much importance, and doubtless other suggestions for improvements will be made in the course of time. Just how many of these can be profitably adopted, an American editor comments, is a question which need not be considered, for the main fact to keep in mind is that a building code must always be a compromise, and it is out of the question to please everybody. The most that can be done is to ensure decided improvements upon existing codes, and this the proposed regulations do in many respects.

They provide for a certificate of occupancy which, it is anticipated, will go a long way towards preventing the misuse of buildings for purposes for which they are unsuitable and for which they were not designed. They give the superintendent of buildings of each borough ample opportunity for the exercise of his judgment in technical matters, yet they provide against favouritism by requiring all his decrees to be published in such a way that anybody interested may have an opportunity of becoming familiar with the rulings as they are made. A particularly earnest endeavour was made to have the various competitive materials of construction treated with absolute fairness, permitting each of them to be used in the most economical manner to give the desired result with the desired safety. Former proposed codes have been strongly attacked on the ground of favouritism toward certain materials. The gentlemen who have given their time to the preparation of this code are above any such attack.

The new proposed code stands upon an entirely different footing from its two predecessors, and it deserves to be discussed with the sober carefulness which was given to its preparation. If it receives such consideration there is a fair prospect of its adoption and of removing thereby from the municipal statutes a code which is obsolete and imperfect in many respects, and is proving prejudicial to good building regulations throughout America because of the tendency of many communities to copy some of its provisions without ascertaining how well or how badly they meet the requirements of public safety.

SOUTH AFRICAN EXPORT SUPPLEMENT.

This South African Export Supplement fulfils a twofold purpose. It indicates in an interesting way for British readers the present building position in South Africa; and it renders an important commercial service to both countries by introducing the producers in the one country to the consumers in the other.

BUSINESS OPPORTUNITIES IN SOUTH AFRICA.

OF all the territories, various and vast, that acknowledge fealty to the British flag, there is none that gives promise of greater or more rapid expansion than the Union of South Africa. When, by the South Africa Act (9, Edward VII., cap. 9), Cape Colony, Natal, the Transvaal, and the Orange River Colony were combined as the Union of South Africa, with the seat of Government at Pretoria and the seat of the Legislature at Cape Town, then dawned an era of prosperity and development of extraordinary and probably unparalleled promise. There is room on this vast continent for almost indefinite expansion. As the resources of the Union are increasingly discovered and exploited new towns spring quickly into existence, and the old ones, growing ceaselessly in area and in importance, signalise the accession of wealth and dignity by the substitution of magnificent buildings for the far less imposing structures that have served their turn and had their day. The country offers an unsurpassed field for commercial enterprise, particularly for manufactures and materials relating to the building trade. For these the South African architect and builder must depend very largely on importation; and it is for the British exporter of such goods to make the most of his opportunities in this direction. This special South African Export issue of the JOURNAL will enable him to make known the merits of his specialities among those by whom such information will be eagerly welcomed. To many British manufacturers this Export issue will introduce a new and profitable market; to many architects and builders in South Africa it will introduce new and excellent goods. The introduction, in fact, should be of the greatest possible mutual advantage.

Corresponding to the magnificent exteriors of the many fine buildings that are now characteristic of the chief cities of the Union of South Africa, there is great sumptuousness in the interior fittings and furnishings; and the luxuriousness of the hotels and town houses finds its reverberations not only in the suburban residences of well-to-do citizens, but even in the remote farmhouses, whose prosperous owners vie with each other in a sort of informal "ideal home" competition. Consequent upon this growth of taste, or at least of the love of comfort, South Africa offers a fair field, also, for the vendor of furniture and domestic plenishings.

Enormous Building Developments.

Building in South Africa, in fact, goes on apace, and reports from all centres are of optimistic tone. In Johannesburg, Pretoria, Maritzburg, Durban, Cape-town, Port Elizabeth, and East London there is at present a vast amount of building in progress. These towns are, therefore, the largest contributory factors in

the matter of indents for manufactures and building materials which help to swell the ever-increasing volume of the general South African trade; upon which all British and Continental exporters have—and will continue more and more in the future to have—an alert business eye. There is, indeed, at the present time great scope for the energy and resource of Home exporters, for the general condition of trade has all the appearance of an abundance of money continuing in circulation. All those merchants who know everything about advertising and pushing goods, and how to keep their names prominently to the front by means of trade journals, have during the past year been doing an extensive and flourishing business, and many of them have sent competent men out to the country itself to establish branches and agencies on a sure and business-like basis. Evidently there has been ample justification for this, as they may now be seen settled with splendid stores and warehouses in the best parts of the different towns, particularly in Johannesburg.

State of Trade.

During 1911, on the Rand alone the value of plans passed was £2,571,611. Johannesburg showed an increase over the preceding year of about £470,000, the plans passed during 1911 being of the value of £1,810,754. The figures for Pretoria reached a total of £149,434, while in 1910 they were £1,121,407, which, of course, includes several large Government building contracts, such as the Union Buildings. The works in hand during the year in the four important outside mining localities referred to above all show six figures, and have not fallen back so much as might have been expected after the abnormal progress in the year 1910. A gratifying feature revealed by the figures is the fact that in the coastal towns there has been marked activity. Durban, Port Elizabeth, and East London give striking proof of this, and Capetown is within an ace, figuratively speaking, of her standard in the preceding year. Kimberley has also made a considerable stride with £68,440, as compared with £20,000 in 1910. Bloemfontein shows big improvement, the figures amounting to £36,184, as compared with £9,215 in the year preceding. In Natal there has been considerable progress, especially in Durban, the figures for the post for 1911 being £224,197, while in 1910 they were £189,201.

Expansion of Pretoria.

Pretoria contributes about £150,000 a year towards the erection of new buildings, and this is irrespective of £1,500,000 for Government works at present in progress. The eyes of the world are now on Pretoria, be-

cause of its great political and industrial development, and a new period of progress is certainly in store for the Administrative Union capital. In order to keep abreast with this state of advance and prosperity, many new buildings will naturally arise in the course of the present year, and amongst them, it cannot be doubted, there will be substantial, dignified, and modernly equipped structures, besides numerous well-built residences for a growing population. The Home exporter should find Pretoria only second to Johannesburg as a veritable mine of wealth for the disposal of his wares.

Building in Natal.

Apart from these large centres, Natal offers tempting inducements to the exporter during the present time of great structural progress. Durban especially is going ahead at a great rate, and Maritzburg is a fairly good rival at present in the matter of building enterprise. The former has an estimated cost of buildings for 1911 to its credit of £224,197, compared with only £189,201 in the year preceding. Certainly the prospects of the future of Durban from a building point of view are very encouraging. As a seaside holiday resort it is growing every year in popularity, and its Municipality is one of the most progressive in all South Africa. This is reflected in enlarged building operations and larger sales for all classes of manufactures. Building in Maritzburg during the past year revived to a remarkable extent, operations being largely in excess of previous records.

Growth of Building in Cape Colony.

In the Cape Colony we find that 1911 has been a year of exceptional building growth. Official figures put the value of buildings for Capetown alone at £96,492. East London more than doubled in building activity during last year, the estimated cost being returned as £46,294.

It will be seen that in the Transvaal, Natal, and the Cape Colony there has been a most satisfactory expansion, and the future is even more encouraging in every department of the building trade. The Orange Free State has also not lagged behind, for we find that the Bloemfontein Corporation passed plans last year representing a value of £9,215.

Value of Building Imports.

It having been shown how building has progressed in South Africa during the past year, with an indication of the vast possibilities for the future, it will be of general interest to give some statistics respecting the imports for the Union in 1911. The Department of Commerce and Industries of the Union of South Africa issues monthly statistics of the value of certain building imports, and it will be found from the appended returns that the total building articles imported during the twelve months of 1911 were valued at £2,735,013, compared with £2,734,809 in the preceding year. The two years, therefore, appear to have been pretty level as far as imports in the building line are concerned.

Figures for twelve months ended December 31, 1911 and 1910:—

Customs Returns for January, 1912.

The following are the Official Customs returns for the Union for January of the present year:—

Capetown: Imports, £565,142; exports, £3,505,014; gross customs revenue, £70,658.

Port Elizabeth: Imports, £683,624; exports, £1,323,152; gross customs revenue, £67,233.

East London: Imports, £310,060; exports, £271,532; gross customs revenue, £36,384.

Durban: Imports, £771,839; exports, £583,909; gross customs revenue, £87,400.

Johannesburg: Gross customs revenue, £63,642.

Laurenço Marques: Imports, £515,016; gross customs revenue, £15,604.

Other ports and stations: Imports, £31,442; exports, £128,863; gross customs revenue, £17,374.

G.P.O.: Gross customs revenue, £9,094.

Total imports, £2,877,123; total exports, £4,812,470; total gross customs revenue, £367,989.

The Capetown exports include gold. The duty collected by magistrates in the Orange Free State is not included.

Trade and Customs Returns, Union of South Africa.

Statement showing the total value of the imports of merchandise and of the exports of South African produce into and from the various ports, and also the total value of the imports and exports into and from the Union of South Africa during the month and twelve months ended December 31, 1911, as compared with the corresponding periods of 1910:—

JOHANNESBURG, "THE GOLDEN CITY."

THE old galvanised iron shanties used in the very early days as the offices of budding gold-mining magnates of Johannesburg are not yet completely forgotten. The old pioneer of about twenty-four or twenty-five years ago can remember such grimy but busy "cabins," in which the foundations of large fortunes were often laid. Those who recollect 1886 and 1887, when the ox-cart toiled through the mud of what is now Commissioner Street, also the flimsy structures of canvas and boards that did duty for houses, and the treeless trails called streets, marvel at the magic change which has taken place since Ferreira Town, with its little collection of canvas tents, one of which was used as the Mining Commissioners' office, was started. The goldfields were then a wilderness; but even here it was that, from such an insignificant beginning, Johannesburg evolved itself. The Standard Bank was perhaps the most pretentious building, and this was a miserable-looking little wattle-and-daub structure. Gazing at the present handsome and palatial bank building at the corner of Commissioner and Harrison Streets, one feels almost overwhelmed with amazement at the contrast between the old order and the new. The Standard Bank is truly a wonderful institution, for it has led South Africa through many tight places. It has been the great deposit as well as the great discount bank, and has given a thorough business training to thousands of Colonists, both Dutch and British. It is most wonderful, therefore, to record that it started its business in Johannesburg in the tiny and grimy-looking building in Ferreira Town, just referred to.

In 1886.

A year of two after the founding of Johannesburg, in 1886, it began to draw to it capital, labour, and intelligence. Unlike the feverish fury, however, to make wealth rapidly, the building of the town proceeded steadily. Mr. H. W. Struben had found gold, and the prospectors thus attracted to the district soon made the Rand the cynosure of every eye, and prospectors came from all parts of the world to the new Eldorado. In a little more than a year there was a population of above three thousand to be housed. It was then that one could see the wattle-and-daub shanties spring up like mushrooms, and the formerly lonely veldt teeming with human activity. Johannesburg had become the focus of an ever-increasing stream of humanity.

Three Building Periods.

There were three building periods in Johannesburg. First, the corrugated iron stage; secondly, the more pretentious brick erections; and, thirdly, the clearing out of these to make room for the magnificent structures now existent. Before dealing with these separately, it is of historic interest to mention that the first sale of stands held in 1886 was fairly well attended, and that the amount realised was £19,000. The portion sold was that now known as Central Johannesburg, and it will astonish people nowadays to know that stands in the vicinity of the Old Exchange, Commissioner Street, fetched only £300 to £400, the latter price being paid for a corner site. Away from this centre, however, the prices dropped considerably; but it must be remembered that standholders had to pay ten shillings a month stand licence, and after a few months many stands were abandoned from this cause. It was on some of these stands that the great business structures in the centre of Johannesburg were in after years to be erected, and for which afterwards £30,000 and £40,000 were paid, but which in early times could have been bought for a mere song. So wonderful has been the magical change in the development of the Golden City that it has grown up like a creation of Aladdin's lamp!

Iron Shanties.

The second sale of stands was held in January, 1887, and was more successful than the first, bringing £26,000 into the coffers of the Dutch Republic. These included some stands that had not been sold at the former sale, and also a few residential stands on the Hospital Hill. At this date the appearance of Johannesburg was that of a number of straggling galvanised iron shanties. What are now properly-defined streets, all finely paved and macadamised, were then trackless patches of sand, with huge boulders interspersed, so that it was difficult for the pedestrian to move about, especially at night. To the north there were a few mud-brick houses; Hospital Hill retained its pristine ruggedness; while to the south two or three small and insignificant wooden head-gears were the precursors of the mighty modern steel head-gears of to-day. There were no dump heaps, and there was absolutely none of that complicated present-day mine equipment; in fact, from where the Kimberley Road enters the town at Ferreira to Booyesen's Hotel was nothing but virgin veldt.

Progress of Building.

None of the suburbs had been thought of, and it was a memorable event when Julius Jeppe erected a hut—"Rose Cottage"—with a thatched roof on Natal Spruit. But within eighteen months after the date of the first sale of stands Johannesburg began to assume the definite appearance of a town. The gaps between the houses had rapidly filled, and though there was nothing in the shape of a building that could be said by the wildest stretch of imagination to boast of any architectural beauty, some, at least, were substantial. This was the beginning of the first building period referred to. The first corrugated-iron erections comprised shops, canteens, shanties, stores, and offices of different kinds for the business of the mushroom "dorp." An old Transvaaler afterwards erected a brick hotel. This was at the east end of Ferreira Camp, where the road turned down to Booyesen's. From this he quickly retired in favour of Bussey, who later built the "Central" in Commissioner Street.

A New Era.

It was now the dawn of a new era. Gold was being found everywhere, and people still continued to flock to the Rand in their thousands. Farms were proclaimed as public diggings, and claims were pegged out till the country looked like the back of a hedgehog. It was then that Johannesburg became firmly established and the building boom began in real earnest. The big commercial houses of Natal and the Cape Colony had all sent their representatives to spy out the prospects of the gold industry of the Witwatersrand, and their reports were glowing and altogether satisfactory. The primitive tin shanties now began to give way to more substantial brick buildings, which led to what has been described as the "two-storey brick stage." Commissioner Street and the Market Square began to take shape. A post office was designed, which also served the purpose of a High Court. The design was a replica of those to be found in many of the smaller villages to-day, and was ornamented by a number of useless gables out of proportion to the rest of the building. After a few years this was found to be too small, and was replaced by the present building, erected by Mr. C. A. Meischke. Within the last few years the second building proved inadequate to cope with the immense volume of business, and another storey was erected at a cost of £20,000.

Old and New Exchange.

Satisfied with the now assured prosperity of Johannesburg, a large number of architects and contractors were

CUTHBERT'S BUILDINGS, JOHANNESBURG.

STANDARD BANK BUILDINGS, JOHANNESBURG.

attracted to the city. Many different styles of architecture began to multiply, until there was no uniformity in the class of building in any street. The old Exchange, built at a cost of over £100,000 at "the Chains," long remained the chief architectural glory of the town. The architect was Mr. Lennox Canning, who died in the early 'nineties. His partner was Mr. Goad, who was exceedingly popular. Many stories could be told of the fortunes made and lost in this old building. The form of "entertainment" within its walls was a striking contrast to that of the modern bioscope, to which it is now devoted. With the rapid growth and expansion of Johannesburg a new Exchange was, of course, essential, and this was erected in Marshall Square, where it stands as a grand monument to the commercial activity of the Johannesburg stockbrokers of the past and present. The new Stock Exchange cost £160,000, and well has the outlay been repaid. It is but barely nine years since the excavations for it were begun. Lord Milner laid the foundation-stone on April 6th, 1903, and the great financial nucleus was fully occupied by the end of the year. The Exchange embodies a great central hall, the heart of considerably more than 200 offices; and the appanages include a members' strong room, as well as spacious apartments devoted to reading, writing, and billiards. The present membership approaches 500, and the 200 odd stocks quoted on the official list represent a total of well over £100,000,000 sterling.

Rand Club Transformation.

The forerunner of the present lordly Rand Club was once one of the important institutions of the early days; it was a very modest structure, being merely a single storey galvanised-iron tenement, with a 6 ft. verandah. The Rand Club is a striking example of the great progress of the city, being now the possessor and occupier of £120,000 worth of regal premises, containing amongst many other comfortable advantages a grand dining-room, and a library of some 5,000 or 6,000 volumes. The membership is more than 1,500.

Magnificent Buildings.

It is impossible here to describe all the magnificent buildings in Johannesburg that have superseded those of the early days, but it may be confidently claimed that no feature of the history of Johannesburg is more fascinating than the transformation of values which has taken place in the ground whereon the city stands. The ground which five-and-twenty years ago could have been bought for a few thousands to-day is valued in millions, and yields a municipal revenue from all sources of well-nigh three-quarters of a million annually.

The visitor is confronted, the moment he arrives, by the enormous buildings that contain the head offices—the controlling brain, heart, and lungs—of the Central South African Railways. The great Central South African Railway block supplies the "motif" of the picture of substantial well-being that greets the eye in all directions—the strength and confidence of a virile manhood. The old horse-trams that followed the bullock wagons of the early days have now given place to handsome and swiftly running electric cars; the main thoroughfares, once but veldt-tracks, are to-day thronged with a busy people, and resplendent with handsome buildings and richly stocked shops, and the ever-extending landscape is adorned by the prosperous-looking suburban residences that betoken so well the fact that success is well founded and permanent.

Millions Expended.

During the last few years the many fine erections that now mark Commissioner Street, Pritchard Street, President Street, Rissik Street, Eloff Street, and other great thoroughfares, have set a hallmark upon the city to testify to its genuine worth and avow its immense value, for since the war many millions of pounds have been expended on new and permanent buildings.

Transport of Material.

Building to-day on the Rand is attended with hardly any of the many difficulties of the early times, when building contracts were not the cut-and-dried affairs that they are now, and contractors were faced with all kinds of sudden and unexpected obstacles. The railway termini were at Kimberley and Ladysmith, and the rates for the carriage of goods during the dry season proved prohibitive for building material. Merchants used to rush through as much work as possible during the summer months, but lack of transport prevented them from getting up sufficient goods to last them through the dry season, and, as a result, many buildings remained unfinished for lack of some essential detail for which the harassed builder had ransacked the town in vain from end to end. The fluctuations in prices were also remarkable, and the contractor used to make up his tender with one eye on the price-list and the other on the barometer, for an early fall of rain brought transport rates down with a run, while a drought had naturally an inflating tendency. Building material transported from Ladysmith in Natal to the Rand by ox-wagon cost no less than £26 per ton!

Nowadays there is an excellent system of railways, and these are being extended in different directions. The former difficulties of the contractor in getting his material from the coastal towns do not now exist, and huge steel-work structures are now being built, chiefly in the centre of the town. One of the first of these was the great Corner House, Eckstein's headquarters, a notable landmark, with its majestic ten storeys and relatively great proportions. The Standard Bank, already referred to, the handsome National Bank offices, the Bank of Africa, the Natal Bank, Barnato Brothers' great edifice, Exploration Buildings—these are all premises significant of progress and stability. Eastwards we find what is acknowledged to be the finest hotel in South Africa, the Carlton, which cost half a million, and is fitted up to match its value. Eloff Street and Pritchard Street form the Regent Street and Oxford Street of Johannesburg, and their splendid shops compare well with many in "Modern Babylon."

The Skyscraper.

The tin-and-wood shanty is rapidly dying out, though there still remain a few here and there to accentuate by their presence the greatness of the present-day skyscraper. On one side of Market Square, the Post Office, although heightened a few years ago by another storey, has still inadequate accommodation for its immense volume of business, so typical of the strenuous life of the Rand. The Telegraph Department alone works an enormous service daily, both inwards and outwards, and the great cablegraphic service to London and other places overseas totals up to a value of many thousands of pounds weekly. The Market Street side of the square has been aptly described as resembling a bit of Chicago, with its serried ranks of skyscrapers dominated by the towering bulk of the Corner House behind.

Social Life.

The social life of the city, as apart from the domestic element, is exemplified by several high-class clubs—the Rand, the New, the Athenæum Club, the Johannesburg, and others, all of which are luxuriously fitted up. The New Club, a commercial institution, well fitted up for its purpose, comprises more than 1,200 members. The Athenæum is housed in an elegant building in the Dutch style, and is situated rather outside the business rough-and-tumble of the town, and, as it appeals to ladies more than do the other clubs, its functions are correspondingly more social.

Chambers and Flats.

One great feature in the Johannesburg of to-day is the number of huge buildings with shops and offices on the lower floors and chambers and flats above; for example, Hatfield House and Moseley House, in President Street; Castle Block, Water Block, St. James's Mansions, Pollock

HENDERSON'S BUILDINGS, JOHANNESBURG.

Buildings, Adderley House, and others, in Eloff Street; Marlborough House, Corporation Buildings, Sacke's Buildings, and so on, in the Commissioner Street area; Park Gate Mansions, overlooking Joubert Park; Central City Buildings, the Cuthbert Buildings, in Pritchard Street, and many other similar blocks, such as Henderson's, Estcourt, Standard, and Glencairn Buildings. Most of these buildings are fitted with electric light and lifts; several have hot-water service laid on, and they have become a permanent feature of life in Johannesburg.

New Law Courts and Town Hall.

Special reference must be made to the new and imposing Law Courts in Von Brandis Square, superseding the old and hitherto inadequate buildings. This dignified pile is well worthy of the purpose it is serving. Externally the building, which cost £135,000, is very handsome, its elevations being designed as an adaptation of the Italian Renaissance. The style, however, is restrained, avoiding over-ornateness. The designers of the New Rand Law Courts (the Transvaal Public Works Department) have seen to it that there shall be nothing wanting to meet the convenience and enhance the comfort of judges, counsel, solicitors, jurors, witnesses, and all concerned. The main entrance will face Pritchard Street, and has a frontage of 349 ft. Near to this is the fine building erected on Von Brandis Square some three and a half years ago to supersede the old telephone tower, and containing the ganglion of a sound-trans-

mitting system that is claimed to be equal to any in the world. New Municipal Offices are being built on the Market Square, and the old "Tin Temples," as the former ones are called, will soon be but a memory of a great corrugated iron shanty whence emanated, through the "City Fathers," many wise and weighty schemes of civic government and control.

Rand Distributing Centre.

The general tendency of the commercial men of Johannesburg at the present time is to improve and extend their stores, thus proving that they share in the general confidence which is felt in the future of the town. This activity on their part suggests the possibility that under the Union Johannesburg will become a large distributing centre, and that much of the work which is at present done at the coast will be undertaken in Johannesburg. The present tendency is certainly towards the establishment of a large *entrepôt* here. That this would be an economical step for the inland Colonies is obvious, when one considers the frequency with which goods have to be handled when they are, as at present, stored at the coast before being sent to the interior. Under the Union there will be no obstacle in the way of railings the goods direct from the coast to Johannesburg, and the work of distributing from this centre will be reduced 50 per cent. Under the Union, Johannesburg will really be a large commercial centre for the Transvaal, apart altogether from the significance of the presence of the mining industry and the support it gives the town.

Expanding Revenue.

Referring to the amazing growth of Johannesburg, mention may here be made of the enormous growth of the revenue of the Municipality. In 1903 the total revenue was £396,301, of which a rate of 2d. per £ produced £264,750; in 1906 it had risen to £988,535, of which a rate of 2½d. per £ yielded £504,942; and for 1909 it was £728,911, to which a rate of 2d. per £ contributed £301,127. These figures of revenue for the year ended in June, 1909, include unpaid arrears of rates, fees, and so on, of which the principal items, compared with the last two years, were: Total levied—assessment rate, 1906-1907, £425,985; 1907-1908, £340,186; 1908-1909, £301,127; sanitary fees, 1906-1907, £169,347. In 1904 the valuation roll of Johannesburg stood at £11,489,540 for buildings and £26,281,434 for land. With Government property of the value of £258,325 in buildings and £1,606,822 in land, the total valuation of land and buildings in Johannesburg amounted to £39,636,121. In the following year the rateable value was £29,772,899 land and £14,105,172 buildings, making a total of £43,878,071. On March 31 the undertakings of the Johannesburg Waterworks, Estate, and Exploration Co., Ltd., and the Vierfontein Syndicate, and the water undertakings of the Braamfontein Co., Ltd., were acquired by the Rand Water Board, and on the same date the Town Council took over the water distribution systems within the municipal area of the Johannesburg Waterworks Co., and the Braamfontein Co. The Council paid the Board £149,250 for the distribution

system of the Waterworks Co., and £7,789 for the Braamfontein distribution system, including reservoirs, mains, and meters, but not stores or pieces of land.

Remarkable Land Values.

The population of Johannesburg before the war was about 80,000 souls, exclusive of natives. Think back now to Ferreira Camp and try to realise what it has all meant to the building trade; the very thought almost takes one's breath away. The streets, which have a length of about eight-five miles, are broad and regularly laid out, stretching to the cardinal points of the compass and intersecting each other at right angles. The city has been well designed, with open central squares, around which are many important commercial buildings for which high monthly rents are paid. It is a fact that for one building £300 a month rent is now charged, the ground on which it stands having at one time gone begging for a purchaser, who, however, when the "boom" came on, paid for the site alone some £30,000. There have been many sensational deals in stands at one time or another. The site on which Messrs. Blinman, Holwil, and Islip's building is situated in Eloff Street was bought from the trustees of the English Church for £110,000, which worked out at £13,750 a stand. By far the most expensive stand sold, however, was a fifty by fifty at the corner of Pritchard and Eloff Streets, on which Messrs. Thorne, Stuttford, have their premises. This was bought from Messrs. Apsey and Co. for £40,000. Many other single stands have brought in over £30,000. One at the corner of Pritchard Street and Von Brandis Street was disposed of for £38,000.

Fortunes Made or Missed.

At this point it is interesting to note that many are the romantic stories of fortunes made and lost in the rise of land values in Johannesburg. Those who have lived through some of its land booms will never forget their experiences. In 1896, for example, the market value of sites in the centre of the town sometimes jumped from hundreds to as many thousands of pounds within a day or two. That was a time of speculative mania. Many a man forgot that there must be a limit to the inflation of prices, and bought as many stands as he could cover by mortgage and deposit, and then held on for some still more fabulous offer which never came. One case illustrates many. A man who, by steady business

in a country town, had accumulated some thirty thousand pounds, was drawn in by the contagion of speculation. Realising all he possessed, he came to Johannesburg and bought stands all over the town on the smallest deposits that sellers would accept. Three men without capital obtained the refusal of a stand in the very heart of the town, and got £1,000. On condition of his financing the purchase they allowed our hero to take a fourth interest at par.

Two days later a powerful corporation offered the syndicate £10,000 for the erf, but they scoffed at the offer. The corporation wanted to build a block of offices; well, the syndicate would do the same. So they set to work, and as with the original purchase, so was the larger scheme, the one man with money was the real foundation of the financial arrangements. Needless to say, he did not realise that the seeming wealth of his three friends consisted solely in options and refusals of sites in and about town. Bonds at 10 per cent. were passed to a leading bank, in which each member of the quartette was made individually and collectively liable for the full amount. By the end of 1897 the edifice was completed. But already the boom had passed. Rent-paying tenants were hard to obtain, and interest and current expenses ate up the syndicate's resources. Presently the three with nothing to lose disappeared, and the man from the country found himself compelled to sell off his holdings in other parts of the town, and finally, early in 1899, the bank took possession of what was left and he returned to his native town a poor man. Many such stories could be related of real-estate booms in Johannesburg and of their reaction, and no one really desires to see another cyclone of feverish speculation. What does gladden the hearts of the real-estate agents of to-day and of those who have the true interests of the town at heart, is the steady rise in the normal value of property throughout the town as a whole. The high-water mark of 1896 has never been touched again, but there is a steady movement in its direction, and Johannesburg real estate is to-day a sounder and surer investment than ever before in its history.

Johannesburg Suburbs.

With the influx of population came the demand for residential suburbs of Johannesburg. Townships soon grew up, and now on every side the "Golden City" is

THE POST OFFICE, JOHANNESBURG.

surrounded by these pleasant localities, which are dotted over with villa residences and verandah cottages, nestling among flower gardens and shrubberies. It is no exaggeration to say that the domestic architecture of the suburbs of Johannesburg compares very favourably with the best work of its kind in any of the other Colonies of the Empire.

Profiting by the unrivalled electric tram-service, which brings Belgravia, Kensington, Parktown, Hillbrow, and other suburbs in direct touch with the great business centre, Johannesburg is rapidly settling down to form a permanent home for its citizens rather than a brief abiding-place. This is specially noticeable in the older suburbs—such as Doornfontein, where the many ornate residences, surrounded by spacious and luxuriant gardens, are swelling a tidal wave of prosperity through New Doornfontein down the beautiful Bezuidenhout Valley. Jeppes, too, has caught the public taste—and small wonder, for there are many charming spots to be located in the Belgravia and Kensington extensions. Jeppes has become the domestic headquarters of an extensive middle class, many of whom own their houses, and may often be seen enjoying their well-earned leisure hours in the lovely avenue in Belgravia, or luxuriating under the shade of the great plantations in Kensington.

The most fashionable suburb of to-day, however, is Parktown, with its many fine houses embowered in trees. Beyond, in 1888, the Braamfontein Estate Co. planted the lovely forest known as Sachzenwald on a kopje. There is a delightful drive through the avenues which intersect the Sachzenwald on to Craighall, which has won its way into popular favour. In the way of scenery there is much to interest one on the estate. The hotel and grounds, which have been purchased at a good round sum, are attractively designed and prettily laid out, and from the position they occupy on top of the hill a commanding view is obtained of picturesque country. Plainly visible are the townships of Parktown North, Melville, and other well-populated suburbs. The main avenue, with its stately trees and broad way leading to Craighall Park, is another feature of interest of the estate which cannot fail to attract notice. On the west and south sides of the hotel broken stretches of water which have been caught and collected by the surrounding

hills glisten in the sunlight, Craighall being particularly fortunate in possessing an abundant supply. The lake itself is a fine sheet, where boating can be had in the most favourable circumstances.

Auckland Park is also a popular residential suburb; and to the east are Hillbrow, the Berea, and the road to Orange Grove. During recent years the value of land in this area has gone up immensely, and much building has taken place. On the south, beyond the mines, extend Booysens, Turffontein, Rossettenville, and other townships. The west has also been developed, and far-reaching schemes have been mooted for the opening up of additional townships in the Langlaagte district. Building in all these localities is going ahead still, and is likely to continue to do so, for Johannesburg is now thoroughly settled down to be recognised as a place where its people have come to stay.

Johannesburg Newspaper Buildings.

Johannesburg possesses two morning and two evening newspapers—the “Transvaal Leader,” “Rand Daily Mail,” “Star,” and “Chronicle” respectively. The “Leader” building in Harrison Street is an imposing pile, and inside it is equipped with the most modern machinery and appliances. “The Master Builders’ Journal” is one of the monthlies produced for the proprietor at the “Leader” office. Recently the Annual connected with that journal was entrusted to them, and the work completed would have done credit to any Home printers and publishers.

The “Rand Daily Mail” are at present erecting new premises, having outgrown their present accommodation in Corporation Buildings. The new structure is neatly designed, and will occupy a corner of Rissik Street, nearer to the railway station. The “Sunday Times,” one of the most popular Rand weeklies, is housed at the “Rand Daily Mail” office.

The “Star” is the leading evening paper, and occupies a large building in President Street, where it has been housed for many years.

The “Chronicle” is a new “evening” started as a penny paper. There are various other mining and social journals, and altogether Johannesburg is well provided with up-to-date journalism and literature.

DURBAN, SOUTH AFRICA'S CHIEF PORT.

ANY work dealing with the progress of South Africa during the past half-century would be decidedly incomplete if some space were not devoted to what has been described, with good grounds, as the chief port of the Union of South Africa, that is to say, Durban, or Port Natal, as it is generally denominated when shipping is referred to. For although it was in 1824 that Lieutenant Farewell, impressed by a previous visit with the apparent opportunities for the formation of a white settlement in the harbour known as Port Natal, obtained the consent of the Governor of the Cape, and formed a private trading company to carry on operations in that neighbourhood, it was not until thirty years later that the town of Durban may be said to have been fairly established, for it was in that year, 1854, that the Lieutenant-Governor of Natal proclaimed the township of Durban to be a borough. Even then, or at least until a very few years previously, the township of Durban consisted of little more than wooden buildings and shanties, and not very many even of these, with no drainage, and the water supply derived from roughly sunk wells. The European population in 1854 totalled 1,204 persons (including women and children), and the value of the property is shown by the fact that although the qualification for civic rights was the possession of landed property of £25 value or the payment of rent to the extent of £5 yearly, only 229 persons were entitled to a place on the first burgess roll of 1854.

Steady Progress.

But Durban, unlike the great diamond and gold-mining camps with their far more rapid progress for periods followed by years of depression, may be said to have from that time onwards made steady, if at times almost imperceptible progress, with the exception of a few years at different stages, particularly during financial trouble in the 'sixties. In 1855 the revenue of the borough was £326, to which the borough rates contributed £283; and by 1860 the revenue had increased to £2,820 for the year, which was greatly augmented in the next few succeeding years by sales of town lands, the place having begun by then to attract attention as a coming commercial centre. In 1864 the valuation of property had attained the respectable figure of £401,576 and the amount realised by the assessment rate of 1½d. per £ was £2,509 17s. Two more years and the valuation had increased by over £50,000; then followed a set-back of over £100,000 for about five years, and it was not until 1876 that the £400,000 was again topped. From then onwards is practically a record of steady progress—if, as already indicated, at times slow, none the less sure. In 1881 the valuation was within a few hundreds of the million, and the revenue had risen to £12,611 from rates alone. A revaluation of property almost doubled the amount of the valuation in the following year, the figures for 1882 being £1,862,488, although the revenue from assessment rates only increased to £15,601, owing to a rate of 1 5-8d. replacing the former rate of 2d.

The Valuation Doubled.

There was comparatively little change until 1891, when the valuation had risen to £2,155,050 and the assessment rate revenue to £23,693, the rate being then $2\frac{3}{4}$ d. in the £. By 1898 the valuation had more than doubled and a $2\frac{1}{2}$ d. rate was bringing in an assessment revenue of £48,634. By 1904 the valuation had once more doubled and the $2\frac{1}{2}$ d. rate (which, as in 1898, included $\frac{1}{2}$ d. water rate) yielded £96,959. In the following year the ten millions were passed and in the year after that the valuation was still another half-million more, while the assessment revenue had by 1906 increased to £109,272. This was the high-water mark, and at last valuation, in 1910, the value was set down at £9,449,260, which at the $2\frac{1}{2}$ d. rate yielded £97,628. The renewed briskness which, however, set in last year will doubtless soon carry the valuation far beyond any figures reached in the past.

Durban a Model Borough.

In what are generally described as municipal trading undertakings, or reproductive works, Durban takes a prominent position in South Africa, and, in fact, it is in connection with these, together with its enterprise in street and road construction, Ocean Beach improvements, and such like, that it is so frequently referred to as the model borough. It has undoubtedly in many instances set the lead to other municipalities, both larger and smaller. In these trading undertakings—water, tramways, electric light and power supply, markets, and telephones—the capital invested amounts to the large sum of £1,402,935, producing an income of £243,252, with an expenditure of £130,683 (excluding interest and sinking funds), and showing a trade profit of £112,569, or 8.02 per cent. on the capital. These figures are for the year ended July 31st, 1910. The total net debt of the Corporation, both for productive and unproductive works, is £2,562,243, so that the trade profit of the trading undertakings for the year would, if capitalised on a 4 per cent. basis, be sufficient to liquidate the net debt of the borough, remunerative and unremunerative, and leave the substantial surplus of £251,982.

Municipal Services.

A brief summary of the history of these trading undertakings will prove of interest in an article on the half-century's progress of the borough. Dealing first with

that very important undertaking, the water supply, we find that about fifty years ago the little township had its main source of water supply from the town pump situated in Smith Street, and although the number of public pumps and wells (they had increased to eighteen in 1877, yielding about 47,000 gallons of water per diem), as well as private wells, increased with succeeding years—particularly in the sinking of the well named Currie's Fountain, and giving a supply of some 50,000 gallons per day—it was not until 1884 that definite steps were taken in the

MAIN ENTRANCE, PRETORIA COLLEGE.

direction of the provision of waterworks on the modern system. In that year the Durban Corporation Waterworks Law was passed, authorising the Council to construct waterworks, acquire land in connection therewith, and levy a water rate not exceeding one-halfpenny in the £ on immovable property. This water supply was derived from the Umbilo River at a point about nine miles from Durban, and the works, which gave a supply of some 200,000 gallons per diem, were opened in July, 1887. At this date the total outlay on borough waterworks, including expenditure in connection with Currie's Fountain, had been over £46,000, exclusive of interest on loan. The supply rapidly led to increased demand, and additional supplies had to be obtained by pumping from the Umhlatuzan River, and eventually, in 1894, the present main source of supply, the Umlaas River, was tapped. Various extensions of the work there have been made from time to time, the higher reaches of the Umlaas River having had to be tapped, and a huge dam constructed at Camperdown, some thirty-five miles from the intake, until at the present day the total daily delivery capacity is over 10,000,000 gallons. The total capital outlay has been £610,735, but £55,179 has been written down by annual votes from revenue, etc., so that the capital outlay at July 31st, 1910, stood at £55,556. The income for the year was £54,981 and the expenditure £12,337, showing a trade profit of £42,644, or 7.67 per cent. on the capital.

Means of Transit.

Next in importance, both from the point of view of capital invested and public convenience, come the tramways. In the early '70's an omnibus service was started, running between Grey Street and the Point, the latter then, as at the present day, the shipping centre. The fare was sixpence all the way; and when one looks at the existing pictorial reminiscences of old Durban, with the heavy sand in the main thoroughfare, West Street, through a portion of which these omnibuses had to be dragged, it does not seem an exorbitant charge for the two and a half miles or so journey. In 1879 the Durban Tramways Co., Ltd., was promoted by Mr. H. R. Collins, civil engineer (now managing director and responsible editor of the "Natal Mercury"), and in 1881 the line was opened for traffic, with four double-decked cars, having canopies and closed sides, and each pro-

viding accommodation for forty persons. This tram-line ran from Russell Street to the Point, and thirty horses were employed on the service. Another tramway was started, and supplied the needs of other portions of the town, particularly the Berea, and in 1890 the two were amalgamated. In 1891 the Town Council first took up the business of tramways, with a horse-car service for the Florida Road district, which was afterwards extended to Marriott Road, making a junction with the company's Berea line. In 1899 the Corporation bought out the company, and at once commenced taking steps for the electrification of the lines, and on May 1st, 1902, the first section was opened for traffic, and early in the following year the whole system, then comprising twenty miles of single track, was electrically equipped. Since then there have been numerous additions, until now Durban is probably the best served municipality in South Africa as regards electric tramways. The revenue for 1910 was £100,665 and the trade profit £33,279, or 7.89 per cent.

Electric Light and Power Supply.

Space does not permit dealing in detail with the other important trading undertakings of the borough, but with regard to the most important of these, the electric light and power supply, it may be mentioned briefly that the capital outlay stands at £289,845 (exclusive of £94,250 written down by annual votes, etc.), the income for the year was £67,893 (excluding interest and sinking fund), the expenditure £39,123, and the trade profit £28,770, or 9.92 per cent. on capital. The electric light service is admirable in every respect, and electricity, both as an illuminant and motive power, as well as for household cookery, is steadily growing in favour. The other trading concerns of the Corporation are the markets and telephones, with more recently the baths, etc.

The Population.

The population has, of course, shown as steady an increase as the progress has been marked in other directions, and from a total of 4,636 in 1864 the figures have now swelled to 64,689, according to a census taken by the Corporation last year (the figures of the Government census just completed not being available at the time of writing). Of the 64,689, 30,030 are Europeans, 2,039 coloured (mixed and other), 16,131 Indians, and 16,489 natives.

PROOF AGAINST TIME,

Corporation Sewage Pumping Station, Durban. Roofed with Ruberoid.

The reliable qualities and numerous advantages of Ruberoid have been recognised by men in South Africa noted for their keen business methods.

Messrs. Lever Bros., Ltd., completely roofed their works at Congella, Durban, with some 140,000 square feet of Ruberoid. It was found so satisfactory for their purpose that they subsequently decided on its sole use for roofing their new works now being erected in Japan.

The Cape Town Corporation, after many years' experience of the use of Ruberoid, have recently specified some 30,000 square feet of Red Ruberoid for the re-roofing of the Early Morning Market Buildings, Cape Town.

We have also supplied large quantities to the Admiralty, P.W.D., South African Railways (for workshops, station buildings, car roofing, etc.), the Corporations of Johannesburg, Durban, Cape Town; Messrs. Stewart and Lloyds, Sir J. L. Hulett and Sons, Ltd., Shaw Bros., and many of the well-known Mining, Sugar, Tea, and Colliery Companies of South Africa.

The use of Ruberoid by such Authorities is an undeniable guarantee of its sterling merits.

Full particulars and Samples for Testing can be obtained from our Agents, who carry large Stocks.

Goods Station for North Eastern Railway Co., Newcastle-on-Tyne.
Concrete Flat Roof covered with Ruberoid.

WEATHER, HEAT & FUMES.

We give you a few important facts about Ruberoid Roofing—facts which have been proved by the best test of all—over twenty years' experience in all parts of the world. Study these and consider if Ruberoid is not worthy of your earnest consideration.

1. The first Ruberoid Roofs laid over twenty years ago are still giving entire satisfaction and show no signs of deterioration.

2. It is essentially a permanent Roofing suitable for the largest warehouses, factories, public buildings, etc., being weatherproof and highly fire-resisting, while its low cost and light weight make it entirely suitable for bungalows, farm-buildings, stables, etc.

3. It is the **only coloured flexible Roofing** manufactured, and is produced in three colours, Grey, Red, and Green. The colours are permanent, being an integral part of the roofing substance and do not require renewing—a deep tile Red and an old copper Green.

County Hall, Wakefield.
All Flat Roofs (2,000 yards) covered with Ruberoid.

PRETORIA PAST AND PRESENT.

A Typical Boer Town.

PRETORIA is no more the "Sleepy Hollow" that it used to be called. From a tiny "dorp," with the most primitive tin and white-washed houses, it has risen to structural heights that are as marvellous as those of Johannesburg itself. It was always a typical Boer town, and was founded as far back as 1845, when the "Ooms" of the time smoked their pipes and drank coffee on the stoep. Pretoria had for years a wearisomely slow development, which it might still have been pursuing but for the discovery of the goldfields and the impetus of Johannesburg wealth, until to-day it shows all the rush and bustle of a live city. Stately buildings have taken the place of the old thatched-roof dwellings, and the streets are well paved. The new Post Office, the Railway Station, the Union Government building, and the many other public and private buildings, will all, with such fine structures as the present Government buildings and the Palace of Justice, lend a dignity to Pretoria which will make it compare favourably with any town of its own size in any other part of the world.

Much building in the future is bound to go on, for Pretoria is to be the administrative seat of the Union Government, and as such will attract a very large population. It is distant only forty-five miles by rail and thirty-four miles by road from Johannesburg, and it is no far-stretched thought or imagination that many palatial residences will be erected in the near future for well-to-do Johannesburgers and others of the wealthier class coming to this country.

Some Noteworthy Buildings.

The town possesses considerable attractions besides its serenity and healthy climate. It possesses a handsome opera house, several skating rinks, Burgher Park, the Zoological Gardens, swimming baths, the museum, and free library; and among other places of interest may be mentioned the late President Kruger's house in Church Street, where many of the "old hands" who had occasion to visit him will remember the inviting cup of coffee

always ready, and generally served to the visitor on the verandah. These were the history-making days, and in the matter of the evolution of building in Pretoria history will keep on repeating itself. Destiny will make it worthy in the way of architectural beauty of its future in the world's history as the capital of United South Africa.

Colleges and Schools.

The selection of Pretoria as the seat of Government of South Africa by the National Convention of 1908-9 marked a new period of progress in regard to municipal, and especially to Governmental, undertakings. The Transvaal Government, which had a handsome surplus in hand on the eve of the Union, decided that considerable attention should be given to Pretoria. A fine new Boys' College and Normal School had already been built, the plans for the new Post Office were enlarged, and the building now in progress will cost upwards of £130,000. In addition it was decided to provide Pretoria with the following: A University College on the eastern town lands, a Museum and Library in Market Street, and possibly a new Girls' College building later. This, with the splendid Bacteriological Institute to the north of the town, opened in 1908, represents a building programme of about half a million, to which must be added the sum of £50,000 voted by Parliament for the canalisation of that part of the Aapies River which traverses the town, and a further £100,000 just allotted for the establishment of an Agricultural College, which it has been decided shall be built at Pretoria.

The New Government Buildings.

All this is dwarfed by the erection of the new Union Government buildings, which are to cost approximately one million sterling. The scheme for the Union buildings, a long curve of white pillared façade, with a line of red roof above, overlooking the town, promises an effect as magnificent as the site, which has been chosen on the slopes of Meintjes Kop, and provides for the future subsidiary lines of buildings on the lower parts of the slope.

NATAL (MARITZBURG), ANCIENT AND MODERN.

Sixty Years' Progress.

SOME forty-six years ago a Maritzburg citizen described a journey at night along the streets of the city as a Pilgrim's Progress through mud, ruts, grass, ironstones, sluits, and darkness. Very few of the houses, or even the public buildings, boasted a second storey, and nearly all of them were built of green brick, some with plaster upon them to hide their ugliness, and others with nothing to prevent the clashing of colours which their walls and their roofs provided. It is related, too, that in the very early days of Maritzburg's history, a woman on her way home accidentally walked on to the back of an ox where Raven Street now stands, and the quadruped, feeling unwarrantably disturbed, ran off with her and left her some distance from her home.

Rudimentary Housing.

Another story, which shows the primitive conditions under which the people lived, has Governor Pine as one of its foremost characters. Whilst strolling about the vicinity of the town, which at that time was principally confined to a market square and a rudimentary church street, he was enjoying the Town Bush prospect northward, when he was startled by a man, who rushed out practically from beneath his horse's feet, and, with furious gestures, cried, "Get off my house." The excited

individual, with a big family, lived in a cave, which he had dug out for himself, and the Governor and his horse were actually standing upon his roof.

Some Early Buildings.

Some of the very oldest buildings still exist in the city, though the hand of the vandal in the shape of the native labourer has razed many an old relic to the ground during the last few years. The Voortrekkers' Church, which overlooks the Market Square, is amongst the antiquities that still remain. It has had a chequered career, for, after being relinquished for Divine Service when the new Dutch church close by it was built, it has successively been a meeting-house, a fruiterer's, a chemist's establishment, and a deserted building. Latterly endeavours have been made to revive the interest in it which its associations warrant, and, itself a relic, it is to become in its oldest days a museum for the relics of Maritzburg, and be once again put to an exalted purpose from which it has so long been a stranger.

At the other end of the Market Square, before the present fine Police Station building rose from its foundations to a belfry three storeys high, there stood a low angle-shaped building, the city's first prison and police shelter. The prisoners' cells looked out upon what is now the Court Gardens in Commercial Road, and through the iron bars many a plug of tobacco and snuff, and even

supplies of whiskey, so it is whispered, found their way to those incarcerated within.

Mixed Functions.

Some of the advertisements which were to be seen on the old low-roofed shops in Church Street were most amusing. It was evidently a set of emigrants of diverse abilities who first made Maritzburg their home. One elderly man's signboard jutted well across the primitive mud pavement, and stated that he was a bricklayer, plasterer, and general jobber, and, as an afterthought, added, "Dancing parties attended"; and in Church Street a placard was to be seen in the following incongruous terms: "Hair-cutting done and seed potatoes sold here." Maritzburg was a quaint little dorp in those days, with its low-tiled houses and grass-grown streets, but many of the oldest houses are the best built, and to this day testify to the substantial workmanship put into them. Houses may be entered to-day in which yellow wood beams and floor-boards still exist in splendid preservation, fit even now to do another quarter of a century's service. One fine old house, in which old Mr. Pistorius lived, has lately had to give way to the march of progress and be annihilated to make room for the new Government School in Berg Street.

The Old Colonial Offices

were built about 1840, and in their earliest days formed the residence of a Mr. Burgess. He vacated the premises in 1845, when they were leased to the Government, and the beginning of the Natal Civil Service was instituted there. The building was enlarged from time to time. By its side a little shanty stood, built of green brick, which was the first Post Office that Maritzburg ever boasted. A man named Zietmann was the postmaster. His eye-

sight was very poor, and the oldest residents of the city can still remember the old fellow recommending them to search for their own letters and take what they wanted. Those, however, were the old days, when laxity led to no harm, and the honesty which invariably exists amongst small communities was fully in evidence in the city. About fifteen years ago the old Colonial Offices were pulled down, and the present fine structure was erected.

Church Street as It Was and as It Is.

A peep along Church Street as it was and as it is reveals the civilising influence of sixty years. No Town Hall tower raised its flagstaff high into the air as it does to-day; the streets were almost devoid of traffic, and the stores had not been modernised from the low Mediterranean style which was generally adopted. The old oil lamps lit the main street precariously at night, and the trees along the sidewalk, which are now huge sheltering oaks, may be seen in their first infancy protected from the storm and the passing bullock-waggon, with its load jutting out on either side. A glance at modernised Church Street discloses the immense strides which have been made in what is comparatively a short time in the life of a town, and the inhabitants of the city who have inherited these improvements, as well as those who have watched them grow, hope for nothing better than to secure similar advancement during the next half-century. The New University College, compared with the tumble-down shanty which was the realm of the pedagogue in the days of the old Voortrekkers, marks an advance of which the citizens of Maritzburg may well be proud, and every year sees some new architectural improvement, which in time must make the town of the present day as much an enigma to future generations as the town of 1850 is to the present inhabitants.

TYPES OF TRANSVAAL SCHOOLS, P. W. D. P. EAGLE, CHIEF ARCHITECT.

THE Perfect System of Heating

Specially suited for

PRIVATE HOUSES
OFFICES
SCHOOLS
CHURCHES
HOSPITALS
HOTELS
WORKSHOPS
&c., &c.

ECONOMY
SIMPLICITY
LOW COST
PERFECT ACTION
NO PIPE TRENCHES
NO TROUBLE
NO ATTENTION
BOILER FIXED ON
ANY FLOOR

MESSRS. BENHAM & SONS, Ltd., have specially designed this system to meet the MODERN and UP-TO-DATE requirements of Architects and Builders.

The system is PERFECT IN ACTION, SIMPLE IN CONSTRUCTION and LOW IN COST, and is specially suitable for buildings where cutting away and making good is an objection to the installation of a heating apparatus.

VERY SMALL SUPPLY PIPES are used and all pipes can be run quite IRRESPECTIVE OF LEVELS. The BOILER CAN BE FIXED ON ANY FLOOR.

A "WIGMORE" Kitchener with roasting fire, two ovens, tiled covings, hot closet with revolving doors and tiled surround.

On the right hand side is shown Benham's "Wigmore" Independent Boiler for hot water supply, with cylinder over.

Shop Front erected in Regent Street, by

FREDK. SAGE & CO., LTD.,

Shopfitting Specialists, 58/62, Gray's Inn Road, London, W.C.

WE are Specialists in the manufacture of high-grade Shop Fronts in all Woods and Metals. We have erected most of the principal Shops and Stores in all parts of the World, including those for the following South African firms:

Messrs. Stuttford & Co.; Cleghorn, Harris & Co.; Gibberd, Bryant & Co.; Harvey, Greenacre & Co.; Cuthbert & Co.; Birch & Co.; Chudleigh Bros.; Parker, Wood & Co.; Sowden & Stoddart, &c., &c., &c.

Architects' details are carefully worked to, or designs are willingly submitted.

Estimates prepared free of cost.

NEW ILLUSTRATED BOOK SENT ON REQUEST.

CAPE TOWN AND SOUTH AFRICAN ARCHITECTURE.

IT is no exaggeration to say that the domestic architecture of South Africa in those fundamental principles which are demanded by the art to make it of any real account whatsoever is considerably in advance of any of the work in the other Colonies of the Empire. This, says a scholarly writer in the "African Architect," is due to the fact that there were certain traditional lines upon which to advance, and that however bad much of the work may be, the high level of this particular branch of architecture will always be maintained by the great number of well-designed homes which are to be found throughout the country. Everywhere, but more particularly in the younger province of the Transvaal, there is evidence that thought has brought about a result of natural beauty simply because of the fitness of design to the required conditions. There is no doubt that the limitation by which the architect was, and is still, surrounded, has had a great deal to do with this. He has kept his work simple, and under this influence ornament that has no message or suggestion, that conveys no memento of a maker's pleasure, rarely exists in the better type of houses. There is little reason that it should, for in South Africa it will ever be found difficult to create a decoration more beautiful than the play of sunlight or shadow upon white-washed or stone walls. Refinement in work does not demand it, and the designer is taught to appreciate the subtle colouring of the varying light, and to be content

with it. This lack of ornamentation is probably the greatest factor in the effect of restfulness apparent in much of the present-day work, and the realisation of this is of the highest importance in South African architecture generally.

Domestic Architecture.

The one serious æsthetic failure in domestic architecture in the country is the almost universal use of corrugated iron for roofing purposes. Time, however, will rectify this, and already tile factories are established at important centres where really good roofing material is being manufactured.

There are, however, many possible improvements in South African work. A real obstacle to an advance towards the more simple and suitable method of building is the ignorance of that section of the building public which demands the cheap and the showy, and, further, the want of traditional training amongst builders and workmen. When the country's architecture rids itself of such vices as plaster work jointed to imitate stone and half-timber work painted on buildings innocent of framing; when it learns to protest against following out in one material a style that had its birth in another; when South African architects realise that the climate of the country with its constant sunshine and clear atmosphere renders particularly unsuitable any attempt to reproduce in its entirety the English type of domestic buildings, then only will they attain that perfection in their work which will

HERBERT BAKER, F.R.I.B.A., ARCHITECT.

THE RHODES MEMORIAL, CAPE TOWN. BAKER AND MASEY, ARCHITECTS.
STATUE OF "PHYSICAL ENERGY" BY G. F. WATTS.

make it a living art representative of the country's best and noblest traditions.

Ecclesiastical Buildings.

To this branch of the mistress art South Africa can scarcely claim to make any original contribution, nor can it be said that the work reaches anything like the same high level as domestic architecture. The early colonists have left a few simple but beautiful examples of their places of worship, but it is regrettable to admit that the very simplicity of these in design and material lead those who lack the necessary culture and appreciation to underestimate their real artistic and archaeological value and interest. When it is remembered that they are the edifices erected in a period with which almost every Dutch family is proud to be associated, it is difficult to understand how tradition has been so utterly discarded for the monuments of ugliness which are yearly raised by the Dutch people for the purpose of worship.

The same criticism must be made about the buildings of the Anglican Church. These are generally designed in a debased Gothic style, as exotic to their environment as was the Gothic work introduced into Italy at the end of the fourteenth century. It is sometimes argued that the reason for this is the endeavour to retain the links and traditions of the great Gothic cathedrals of England. With this view the sincere builder can have no sympathy. The style demands treatment in stone, which as a rule cannot be afforded where accommodation is required beyond the sum allotted for expenditure. The result is that in most cases the work is done in cement with sham joints, and ends in a ghastly failure. Those who have studied the question carefully realise that "the land cries out for domes, big detached and far seen against the clear blue sky." If South African ecclesiastical architecture is ever to be of any consequence, it must develop upon different lines from those which it has hitherto followed. Let her architects remember how conspicuously the Roman failed when he treated architecture as an art which had little or nothing to do with building, and merely attempted to copy the Greek skill and taste, forgetting that it was the outcome of a real construction. The basis for their work will be found rather in the Byzantine style, with the long ranges of columns of the basilica and the Eastern dome and something of the Arabian art to be found in the more southern portion of Italy. All the material is at hand to fully develop the style, and for their interior decoration many coloured marbles, too small in size for most purposes, are being quarried locally which provide excellently for the use of *opus Alexandrium*.

National Monuments.

A young country just developing into manhood cannot be expected to possess any considerable works of art or historical monuments. These are the products only of a nation with generations of civilisation behind it;

PRETORIA CATHEDRAL INTERIOR.

:: MACHINE :: WOODWORKER

Sawmiller, Box and Case Maker, and
Estate Sawmill Manager

28 pages Monthly - One Penny
Annual Subscription - - - 2/-
post free to any part of the World

THIS publication is a marvellous pennyworth.
It has all the best technical writers.

It deals with all matters and problems
identified with woodworking machinery, plant,
and appliances.

There is nothing else like it.

It appeals to all Woodworking trades at
home and in the Colonies.

Besides articles upon the operating of wood-
working machinery, and the management of
saws, etc., it contains Lessons on Handrailing,
Machinery and plant for Cabinet and Furniture
making, numerous Questions and Answers, etc.

but it is in countries which are establishing themselves, making their laws, cementing their politics, bringing their communities into order after fighting, that public spirit should be found at its highest point, and in which art should find its greatest opportunities. In a highly civilised State, where all are satisfied and there are no wars or rumours of wars, where life is easy and men are lazy and luxurious, there can be no great stimulus. South Africans are beginning to realise their obligations to those who, having laid the foundations of the nation, have passed away, and are building the monuments by which future generations may remember them.

On the slopes of Table Mountain, under the shadow of the grim peak over which the winds of all the seas pour in cataracts of cloud—on the slopes of that mountain to which he was wont to tell worried and disputing politicians to turn from “their trouble of ants” to its calm, they have erected a memorial to

The immense and brooding spirit

of Cecil Rhodes. The site is one of the finest in the world. It looks out upon the two great Atlantic and Indian oceans, and before it spread the great plains—which Rhodes wanted to see “dotted with homes”—until they reach the barrier of the Hex River Mountains, beyond which lies the mysterious north. The tranquil immobility of this great grey monument, “hewn from the granite ribs” of Table Mountain itself, promises to defy the ravages of time, and looks as though it would endure as long as the everlasting hills themselves. The design is simple, and closely follows the Greek Doric of the Sicilian temples. Flanking the great flight of steps are eight bronze lions, the last creations of the late J. M. Swan. The whole forms a magnificent setting for Watts's “Energy,” that bronze figure “mounted on a gigantic steed ready for the race, but reigning the horse in while looking into the distance at the destination which he means to reach. Forgetting the struggle it has cost him to mount to his seat and grasp the rein, he thinks only of the work that is yet to be done.” Looking with that great image across the mountains to the north, it may be felt that here, if anywhere, is a land where:

*Some work of noble note may yet be done
“Not unbecoming men that strove.”*

These wise words, spoken by one who had helped in the building of the new nation, aptly interpret the impression created by the entire monument. It is fitting that the man who, more than any other, strove to lay under contribution the great Greek and Roman models in his schemes for memorialising those who had served and given up their lives in the country's service should have erected to his memory just such a work as he himself often contemplated to the memory of others.

It is to his munificence that South Africa owes the two other monuments of importance in the country; the Shangani memorial on the plains of Rhodesia, with its bronze tablets by Tweed, erected in memory of Alan Wilson and his gallant band, and that other near Kimberley to commemorate the siege and those who fell there. Architecture in South Africa owes much to Cecil Rhodes, who, with the building ambitions of a Hadrian, was responsible for some of the most beautiful examples of the art which the country possesses.

Public Buildings.

No public building of a distinctive character has as yet been erected in South Africa. Of city architecture the country boasts no artistic triumph, civic buildings being almost entirely a replica of what already exists in England; but of the new and greater South Africa there is much to expect. The result of Union has been the demand for increased accommodation for public departments and the housing of the Civil Service of the country. In the northern province especially large sums are being spent by the Public Works Department in preparation for that greater part which the Transvaal is to play in the country's future. Law Courts, museums, railway stations, colleges, and schools, adequately equipped, are being built throughout the province; but the greatest achieve-

ment of the Government, and what is likely to be one of the great architectural monuments of the future, is the magnificent pile of offices for Ministers and officials which is being erected in the administrative capital. By a bold

BUSINESS PREMISES, PARLIAMENT STREET, CAPE TOWN.
BAKER AND MASEY, F.F.R.I.B.A., ARCHITECTS.

stroke of genius and originality, on the eve of union, the Transvaal Government decided to place its great centre of administration on one of the hills surrounding Pretoria. Meintjes Kop, the chosen site for the Union Buildings, is the most considerable eminence on the northern side of the town. The actual plateau on which the structure will stand is little more than half-way to the top. Here the natural shelf formation is broken by a small kloof widening out into a semicircle, which suggested the plan of the Union Buildings. On either side of this ravine will be a rectangular block of offices, connected where the ground rises above it by a semicircular colonnade, forming both a covered passage between the two blocks and connecting each to the necessary common rooms which are placed behind the colonnade. It is here that the architect of the building has displayed his genius for design. The effect of this colonnade, which is at a higher level than the main road and terrace in front of the building, and consequently necessitates a series of steps and terraces leading up to it, will be to give the building the appearance of rising with the hill and resting naturally upon it. These steps and terraces, necessary in themselves to the design, are arranged between the two office blocks and against the large semicircle in the form of an amphitheatre.

Dignified simplicity is the "note" of the building; and in the entire conception the scheme has been subordinated to a dominant idea, just as in the Acropolis it was an essential part of the policy of Pericles to keep present in the imagination of the Greek citizens a sense of the divine importance of the State.

Herbert Baker's Work.

South Africa has been fortunate in the possession of an architect who could prove himself capable of so worthy a conception. Herbert Baker, who is responsible for the Union Buildings, since he came to the country some twenty years ago, has been the most considerable influence in South African architecture. To him is due the revival of interest in the early Dutch work and the pressing into the service of the modern homes such features as could be adapted from the old Cape homesteads, thereby carrying forward the style. Throughout the length and breadth of the land are examples of his master hand, the real significance of which can only be tested by the imprint that such works as "Groote Schuur," the Rhodes building at Capetown, and his most recent masterpiece, must leave on the creations of future generations of architects.

B. T. BATSFORD'S STANDARD PUBLICATIONS FOR ARCHITECTS & BUILDERS.

CIVIC ART: Studies in Town Planning, Parks, Boulevards, and Open Spaces. By THOMAS H. MAWSON, Hon. A.R.I.B.A., Lecturer on Landscape Design, University of Liverpool. Containing upwards of 350 pages, illustrated by two Coloured Plates, and 275 Drawings and Photographs of English and Foreign Examples, finely reproduced in line, half-tone and collotype. Crown Folio, handsomely bound in buckram, gilt. Price £2 10s. net.

ENGLISH HOUSE DESIGN: Being a Selection and Brief Analysis of some of the Best Achievements in English Domestic Architecture from the 16th to the 20th Centuries, together with numerous Examples of Contemporary Design. By ERNEST WILLMOTT, F.R.I.B.A., Architect. Containing 222 pages, with 155 Illustrations of Exterior and Interior Views, chiefly full-page reproductions of choice Photographs, with numerous Plans. Royal 8vo, cloth, gilt. Price 10s. 6d. net.

MODERN COTTAGE ARCHITECTURE, illustrated from Works of well-known Architects. Selected and described by MAURICE B. ADAMS, F.R.I.B.A. Second Edition, revised and enlarged, containing 83 full-page Plates from Photographs and Drawings, and 54 Illustrations of Plans, Elevations, etc., in the text. 4to cloth, gilt. 10s. net.

MODERN SCHOOL BUILDINGS, Elementary and Secondary. A Treatise on the Planning, Arrangement, and Fitting of Day and Boarding Schools. By FELIX CLAY, B.A., Architect. Index, and Portfolio	12/6	(Inland).	

The Architects' and Builders' Journal.

"THE ARCHITECTS' AND BUILDERS' JOURNAL" is a publication which, while giving due attention to the higher aspects of Architecture, deals particularly with the more practical side of the art. Informative articles, by acknowledged experts, upon all points of construction are standing features of the Journal; and the very latest news of building trade activity is given week by week. All subscribers are entitled to the services of specially retained experts whenever confronted by a difficulty.

"DETAILS, OLD AND NEW," showing measured drawings and photographs of the elevations of noteworthy work, are a regular feature of each weekly issue. This valuable series commenced March 22, 1911.

Every Wednesday, Price 2d. Annual Post Free Subscription, 10/10; Canada, 13/-; elsewhere abroad, 19/6.

The Liverpool Architectural Sketch Book.

Being the Annual of the School of Architecture of the University of Liverpool. The Liverpool Architectural Sketch Book, comprising some 112 illustrations, affords striking evidence of the forward movement in Architectural Education. The drawings are skilfully executed, and have been fully reproduced on heavy art paper, in a handsome 4to volume.

Vol. I. 1910. Price 2/6 nett.

Vol. II. 1911. New and Enlarged Number. Price 5/- nett.

The Volumes will be sent Post Free (Inland) if remittance accompanies the order.

Recent English Domestic Architecture.

Edited by MERVYN E. MACARTNEY, B.A., F.S.A., F.R.I.B.A.

English Domestic Work is of acknowledged supremacy in the domain of Architecture. These Special Issues give a magnificent collection of the work of the best architects of the day, and are of the greatest value, not only to architects and builders, but also to those having estates to develop, and others who are interested in house-building.

1908. Vol. I. Out of print.

1909, 1910. Vols. II. and III. Price 7/6 each nett.

1911. Vol. IV. Price 5/- nett.

The Volumes will be sent Post Free (Inland) if remittance accompanies the order, otherwise postage will be charged.

Practical Notes for Architectural Draughtsmen.

By A. W. S. CROSS, M.A., F.R.I.B.A., AND A. E. MUNBY, M.A., A.R.I.B.A.

Gives in most convenient form for use on the drawing-board examples with concise rules, explanations, and dimensions for preparing Designs, Perspectives, and Working Drawings for Classical Architecture with rapidity and precision. It contains a mass of valuable information with carefully drawn examples. How to draw "The Orders" correctly with the smallest possible amount of study and work is shown by the invaluable drawings and data given in this publication.

Price 15/- nett, Post Free (Inland), including Portfolio.

Specification :

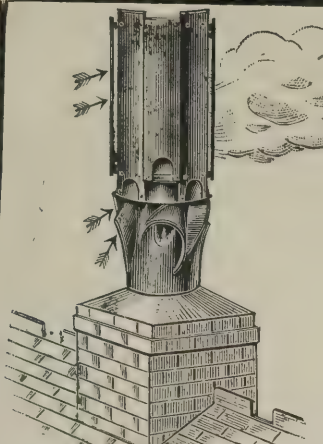

FOR ARCHITECTS, SURVEYORS, AND ENGINEERS, WHEN SPECIFYING. Among the Important Special Contributions appearing in this Volume are the following:—Cinematograph Theatres, Notes on Motor Garages, Glossary of Technical Terms, Half-Timber Construction, Methods of Illumination (Acetylene Gas, Coal Gas, Oil, Petrol Gas, etc.), Working Drawings of some Important Recent Buildings. The work is the "Standard Encyclopædia of Technical Information" on all subjects which arise when specifications are being prepared.

No. 14, 1911-12. Price 3/6 nett, postage (Inland) 6d. extra.

Over 500 pages, 13 in. by 9 in., strongly bound.

Orders should be sent to The Manager, TECHNICAL JOURNALS, Ltd.,
Caxton House, Westminster, S.W.

Clean Detail Drawings

John Hassall, R.I., writing of *The GEORGIAN* drawing pencils said: "I find they have all the necessary qualifications for black and white work, in that they rub out without leaving any sign on the whitest boards." If you have detail work to do you will realise what this means. Your finished drawings will not appear blurred because of the grey lines which you cannot erase. Make a trial with them now. All the Qualities; half the Price.

RUBEROID

Ruberoid Roof Talks. No. 5. "BUNGALOW ROOFS"

A green Ruberoid Roof for a Bungalow of this description gives an artistic effect impossible to improve upon. The rich green colour will neither fade nor wash out; being part of the material, it is as permanent as the Roofing itself. Ruberoid, moreover, is so light and easy to handle, and its flexibility enables it to be bent to the shape of any roof without trouble. Ruberoid is both rain-proof and heat-proof, and its remarkable durability has been proved in many instances where it has been used for twenty years without repair. Another great advantage in a Ruberoid Roof is that it does not require metal flashings, and is just as suitable for flat as for pitched roofs. Ruberoid is also produced in an attractive Red—rich and warm in colour, and will harmonise with any surroundings. Before you decide upon your roofing material send for the Ruberoid Book of Facts and a sample of Ruberoid Roofing. These are sent free on application to—

Decide to use Ceresit

Wherever you wish to
exclude moisture or damp
decide to use Ceresit. By
doing so you are **guaranteed**—not
promised—an absolutely "dust-dry"
structure under all conceivable conditions.

Ceresit, the **sure** Waterproofing, **keeps buildings proof** against
damp or water percolation, even though subjected to heavy
pressures. It is the cheapest, the simplest, and the
only thoroughly efficient waterproofing medium known.

CERESIT

COMPLETE LIST OF CONTRACTS OPEN.

In this list are included, as a rule, only those contracts for which tenders are returnable about five days or longer after the date of this issue. Unless expressly stated to the contrary, all deposits required for bills of quantities, etc., are returned on receipt of *bona-fide* tenders. The words "Fair Wages Clause" inserted in certain paragraphs signify that persons tendering must conform to a fair wages clause in the Contract, which requires them to pay the rates of wages current in the district.

BUILDING.

July 1.—POST OFFICE EXTENSION, Peterborough.—Extension of Peterborough Post Office for the Commissioners of H.M. Works and Public Buildings. Drawings, specifications, and a copy of conditions and form of contract may be seen on application to the Postmaster at Peterborough Post Office. Bills of quantities and forms of tender may be obtained at H.M. Office of Works, Storey's Gate, London, S.W., on deposit of £1 1s. Tenders must be delivered to the Secretary, H.M. Office of Works, etc., Storey's Gate, London, S.W.

July 1.—COTTAGES, Stratford-upon-Avon.—Erection of workmen's cottages in blocks of six, on land adjoining Birmingham Road, for the Town Council. Plans and specifications may be seen, and bills of quantities and form of tender obtained, at the office of Roden Dixon, Borough Surveyor, Municipal Offices, Stratford-upon-Avon, upon deposit of £2. Tenders must be delivered to the Town Clerk, R. Lunn, 1, Sheep Street, Stratford-upon-Avon.

July 1.—HOUSE, Hereford.—Erection of a house in connection with the Victoria Eye and Ear Hospital, Hereford. Plans and specifications may be seen at the offices of Nicholson and Clarke, Architects and Surveyors, Cathedral Chambers, Hereford. Bills of quantities will be supplied on deposit of £2 2s. Tenders to be delivered at the Hospital, addressed to the Secretary.

July 1.—ALTERATIONS, Workington.—Execution of the several works required in the alterations to the Carnegie Lecture Hall. Full particulars may be obtained on application to H. Bowman Williams, Borough Engineer and Surveyor, Town Hall, Workington.

July 1.—LAUNDRY, London, W.—Erection of a public laundry, containing approximately 30 washing troughs and a similar number of drying horses, together with the necessary equipment, at the rear of the Kensal Road Baths, for the Paddington Borough Council. Forms of tender and specification will be furnished upon application to the Borough Surveyor.

July 1.—MORTUARY, Hendon.—Erection of a public mortuary and other buildings near the Council offices, etc., for the U.D.C. The drawings and specification may be seen, and forms of tender obtained, of S. Slater Grimley, M.Inst.C.E., Engineer and Surveyor to the Council, at the Council Offices, on deposit of £2 2s.

July 1.—LABORATORY, Exminster.—Erection of a new pathological laboratory at the Devon County Lunatic Asylum, Exminster, for the Committee of Visitors of the County Lunatic Asylum. The plans and specifications can be seen at the office of the County Architect, E. H. Harbottle, Queen Street, Exeter. Bills of quantities can be obtained from F. Bailey, Clerk to the Committee, Castle of Exeter, on deposit of £2, to whom tenders are to be sent.

July 1.—SCHOOL ALTERATIONS, ETC. Stockton-on-Tees.—Alterations to the secondary schools, Nelson Terrace, for the Education Committee. Plans and specification may be seen, and quantities obtained at the Borough Engineer's Offices. Tenders to be sent to M. H. Sykes, Borough Engineer, Town Hall, Stockton-on-Tees.

July 1.—LAUNDRY, ETC. Canterbury.—Erection of a laundry, boiler-house, and chimney shaft at the Workhouse, Canterbury, for the Guardians. Plan and specification can be seen and bills of quantities and forms of tender obtained on application to the Architect, F. H. Dore, 25, Watling Street, Canterbury, on deposit of £2 2s. Tenders to be delivered to John Plummer, Clerk to the Guardians, 80, Castle Street, Canterbury.

July 2.—SCHOOL ALTERATIONS, ETC. Liverton Mines (Yorks).—Alterations and improvements at the Liverton Mines Council School, for the North Riding of Yorkshire County Council Education Committee. Plans and specification may be seen and forms of tender obtained on application at the school. Tenders to be delivered to J. C. Wrigley, Secretary, Education Offices, Northallerton.

July 2.—RE-ROOFING, ETC. Breage.—Re-roofing and renovation of the Carleen Chapel, Breage. Specifications may be seen on application to J. Pryor, Pengwedna, Breage, and tenders should be sent to Rev. T. Hosking, Porthleven.

July 2.—CHAPEL, Dundalk.—Erection of a mortuary chapel in the Catholic grounds of St. Patrick's Cemetery, Lowdallshill, for the Dundalk Joint Burial Board, in strict accordance with the plans and specifications prepared by M. Sellars, M.I.C.E., Architect, which can be seen at his office, Town Hall, Dundalk. Forms of tender can be had from the Architect on deposit of £2. Tenders to be sent to P. R. Finigan, Secretary, Town Hall, Dundalk. Sureties required.

July 2.—SCHOOL EXTENSION, Luton.—Erection of the Old Bedford Road school extension, for the Town Council. Plans, conditions of contract, and specifications may be inspected at the office of the Borough Engineer, Town Hall, and form of tender obtained on deposit of 10s. 6d. Tenders are to be delivered to B. Penny, Town Clerk, Town Hall, Luton.

July 2.—SCHOOL ALTERATIONS, ETC.—Mountain Ash.—Executing extensive alterations, etc., to the Duffryn Boys' School, Mountain Ash for the Education Committee. Plans and specifications may be seen, and forms of tender obtained, at the office of the Architect, W. H. Williams, M.S.A., Town Hall, Mountain Ash. Tenders must be sent to A. Morgan, Director of Education, Town Hall, Mountain Ash.

July 2.—WARDS, ETC. Manchester.—Erection of new lunatic wards and drainage at the Withington Workhouse for the Guardians. Plans can be seen at and quantities obtained from the offices of Fredk. H. Overmann, F.M.S.A., 48, King Street, Manchester, upon deposit of £1 1s. Tenders to be delivered to David S. Bloomfield, Clerk, Guardians' Offices, All Saints', Manchester.

July 2.—MORTUARY, ETC. Watford.—Erection of a mortuary and post-mortem room, and for additional boiler-house accommodation at the Watford Union House, for the Board of Guardians. Drawings, specification, and a copy of the conditions and forms of contract may be seen upon application to W. H. Syme, F.R.I.B.A., Architect, at 58a, Vicarage Road, Watford, of whom bills of quantities and forms of tender may be obtained upon deposit of £1 1s. Tenders to be sent to Frederick Wilson, Clerk to the Guardians, Watford Place, Watford.

July 3.—POST OFFICE EXTENSION, Aylesbury.—Extension of Aylesbury Post Office for the Commissioners of H.M. Works and Public Buildings. Drawings, specification, and copy of the conditions and form of contract may be seen on application to the Postmaster at Aylesbury Post Office. Bills of quantities and forms of tender may be obtained at H.M. Office of Works, Storey's Gate, London, S.W., on deposit of £1 1s. Tenders must be delivered to the Secretary, H.M. Office of Works, etc., Storey's Gate, London, S.W.

July 3.—LABORATORY, London, E.—Erection of a bacteriological laboratory at their Public Health Offices, White Horse Street, Ratcliff, Stepney, for the Stepney Borough Council. Copies of the stipulations, schedule, and form of tender may be obtained by applying to the Borough Engineer, M. W. Jameson, A.M.I.C.E., Municipal Offices, 15, Great Alie Street, Whitechapel, E., upon deposit of £5. Tenders must be sent to Geo. W. Clarke, Town Clerk, Municipal Offices, 15, Great Alie Street, E. Fair wages clause.

July 3.—SCHOOL ALTERATIONS, ETC. Somerton.—Alterations and additions at the Church of England Schools, Broad Street, for the Managers, in accordance with plans and specification prepared by the Architect, R. Bowring, of Wells, Somerset. Contract plans and specification may be seen with Jno. S. Taylor, Correspondent, Somerton, to whom tenders are to be sent.

July 4.—COTTAGES, Whitehaven.—Building 18 new cottages at Kells, Whitehaven. Plans and specification can be seen at Somerset House, Whitehaven. Tenders to be sent to E. L. Nanson, Somerset House, Whitehaven.

July 4.—MANUAL TRAINING ROOM, Banstead (Surrey).—Building a manual training room at their school, Banstead, Surrey, for the managers of the Kensington and Chelsea School District. A copy of the specification, form of tender, and drawing may be obtained at the offices of their Architect, Cecil A. Sharp, 2, Verulam Buildings, Gray's Inn, W.C., upon deposit of £5. Tenders must be delivered to Henry D. Aslett, Clerk to the Board of Management, Marlesford Lodge, 241 King Street, Hammersmith, W.

July 4.—RESIDENCES, Leeds.—Erection of a pair of semi-detached residences, off York Road, Leeds, for T. Anderton and E. H. Hazzlewood. Plans and specifications may be seen, and quantities obtained at the offices of T. A. Buttery, Lic.R.I.B.A., Architect, Queen Street, Morley, and 1, Basinghall Square Leeds, to whom tenders are to be sent.

July 4.—RESIDENCE, Leeds.—Erection of villa residence, off York Road, Leeds, for O. H. Pinder. Plans and specifications may be seen, and quantities obtained at the office of T. A. Buttery, Lic.R.I.B.A., Architect, Queen Street, Morley, and 1, Basinghall Square, Leeds, to whom tenders are to be sent.

July 4.—SCHOOL, Carnant.—Building a new school (accommodation 514) at Garnant, Amman Valley, for the Carmarthenshire County Council. Plans and specifications may be seen and full particulars obtained at the office of W. V. Morgan, A.R.I.B.A., County Architect, County Education Offices, Carmarthen. Tenders are to be delivered to J. W. Nicholas, County Education Offices, Carmarthen.

July 4.—SCHOOL ALTERATIONS, Pengo.—Alterations and new exits at the Melvin Road school, and redecoration, etc., to various schools for the Penge U.D.C. Education Committee. Specifications and forms of tender may be obtained at the office of the Surveyor, W. H. Longdin, Town Hall, Anerley S.E., upon deposit of £1 1s. Tenders to be sent to C. G. Liddle, Clerk to the Committee, Anerley, S.E.

July 5.—SCHOOL, Sicklinghall (Yorks).—Execution of the following works for the West Riding Education Committee: Sicklinghall New School (builder, joiner, slater, plumber, plasterer, painter, and ironfounder and smith). Plans may be seen and specification with quantities obtained on application to the Education Architect, County Hall, Wakefield. A plan may also be seen at the office of the Divisional Clerk, Harrogate. A deposit of £1 must be sent by separate letter to the West Riding Treasurer, County Hall, Wakefield. Tenders to be sent to Francis Alvey Darwin, Clerk of the County Council, County Hall, Wakefield.

July 5.—POST OFFICE EXTENSION, Bedford.—Extension of Bedford Post Office for the Commissioners of H.M. Works and Public Buildings. Drawings, specification, and a copy of the conditions and form of contract may be seen on application to the Postmaster at Bedford Post Office. Bills of quantities and forms of tender may be obtained at H.M. Office of Works, Storey's Gate, London S.W., on deposit of £1 1s. Tenders must be delivered to the Secretary, H.M. Office of Works, etc., Storey's Gate, London, S.W.

Tenders to be sent to Jas. H. Rothwell, Town Clerk, Town Clerk's Office, Municipal Offices, Brighouse.

July 6.—**CHAPEL, ETC. Ellesmere Port.**—Execution of the following for the Ellesmere Port and Whitby U.D.C.: (1) Erection of cemetery chapel, tool-house, and conveniences, fencing, entrance gates, etc. (2) Laying of a 9 in. pipe sewer, construction of manholes, etc. Plans may be inspected, and specifications and forms of tender obtained at the Office of Thos. W. Francis, Clerk to the Council, Council Offices, Ellesmere Port, to whom tenders are to be sent.

July 8.—**ALTERATIONS TO OFFICES. Fails-worth.**—Alterations and additions proposed to be made to the Council offices, Oldham Road, Fails-worth, for the U.D.C. The plans and drawings may be seen and a copy of the form of tender, conditions of contract, specification, and bills of quantities obtained at the office of W. M. Shimmin, C.E., Surveyor to the Council, Oldham Road, Fails-worth, on deposit of £2. Tenders must be sent to H. C. Broome, Clerk to the Council, Council Offices, Fails-worth. Fair wages clause.

July 8.—**HOUSES. Machen.**—Erection of 30 houses at Machen, Mon., for the Machen No. 1 Building Club. Plans and specifications may be seen and all particulars obtained at the office of Philip J. Jones, Architect, Church Street, Pontypridd. Tenders to be sent to G. D. Jenkin, Chatham Villa, Machen.

July 9.—**POST OFFICE ALTERATIONS. Stirling.**—Alterations and additions to Stirling Post Office for the Commissioners of H.M. Works and Public Buildings. Drawings, specification, and a copy of the conditions and form of contract, may be seen on application to the Postmaster at Stirling Post Office. Bills of quantities and forms of tender may be obtained at H.M. Office of Works, 3, Parliament Square, Edinburgh, on deposit of £1 is. Tenders must be delivered to the secretary, H.M. Office of Works, etc., Storey's Gate, London, S.W.

July 9.—**BRIDGE. Lancashire.**—Construction of Penwortham bridge and approaches over the River Ribble in the township of Penwortham and County Borough of Preston for the Lancashire County Council. The bridge will be 60 feet in width between parapets, and consist of 3 skew spans, each of 90 feet, the whole to be constructed in masonry. The approaches consist of about 500 lineal yards of new road 60 feet wide, and about 100 lineal yards of new road 45 feet wide; also about 270 lineal yards of main road widening. Plans may be seen and copies of the specification and bill of quantities obtained at the County Bridge-master's Office, Preston.

July 10.—**MORTUARY ALTERATIONS. London, W.C.**—Alterations of the public mortuary, Goldsmith Street, and Macklin Street, Drury Lane, W.C., for the Holborn B.C., and other works incidental thereto, in accordance with the drawings and specification prepared by the Borough Surveyor, E. F. Spurrell. Tenders must be delivered to the Town Clerk, Council Offices, Nos. 193-197, High Holborn, W.C.

July 10.—**ADDITIONS, ETC. Cwmgorse.**—Erection of additions and alterations to New Star Hotel, Cwmgorse. Plans and specification may be seen with John Watkins, New Star Hotel, Cwmgorse, to whom tenders are to be sent.

July 11.—**LIBRARY. London, N.E.**—Erection of a branch library building in Brooksbys Walk, Homerton, for the Hackney B.C. Plans and specifications may be seen, and bills of quantities, with conditions, form of tender, and form of contract, may be obtained at the office of the Architect, E. Cooper, F.R.I.B.A., 12, Gray's Inn Square, W.C., on deposit of £2 2s. with W. A. Williams, Town Clerk, Town Hall Hackney. Fair wages clause.

July 16.—**PUBLIC OFFICES. London, S.W.**—Extension of the new public offices, Westminster (superstructure), for the Commissioners of H.M. Works and Public Buildings. Drawings, specifications, and a copy of the conditions and form of contract may be seen on application to Sir Henry Tanner, at H.M. Office of Works, etc. Bills of quantities and forms of tender may be obtained from the Secretary, H.M. Office of Works, etc., Storey's Gate, London, S.W., on deposit of £1 is., to whom tenders are to be sent.

ENGINEERING.

July 4.—**PLANT. Dewsbury.**—Supply of the following for the Corporation: (26a) one 1,000-kw. turbine; (26b) two 500-kw. direct-current generators; (26c) jet-condensing plant for above. Specifications, with form of contract, may be obtained from R. H. Campion, Borough Electrical Engineer, Bradford Road, Dewsbury, on deposit of £1 is. Tenders must be sent to H. Ellis, Town Clerk, Town Hall, Dewsbury.

July 8.—**SUPERSTRUCTURE. Hull.**—Renewal of the superstructure of the bridge carrying the Victoria Dock branch over the Foredyke Stream at Hull for the North-Eastern Railway. The work consists of about 65 tons of steelwork, together with asphalt, and includes the removal of the existing girders and the erection of the new work. Plans and specification may be seen and detailed quantities and form of tender obtained on application at the office of C. F. Bengough, the Company's Engineer at York. Tenders must be sent to R. F. Dunnell, Secretary, York.

July 24.—**PLANT. London, N.**—Supply and erection of machinery and plant, as under, for the Lighting Committee of the Islington Borough Council: 3,000 kilowatt steam turbine alternator, exciter, condensing plant, switch-gear, circulating and steam piping, together with other accessories. Specification, general conditions, and form of tender may be obtained on application to the Electrical Engineer, 50, Eden Grove, Holloway, London, N. A deposit by cheque of £2 2s. will be required. Tenders to be addressed to Wm. F. Dewey, Town Clerk, Town Hall, Upper Street, Islington, London, N.

(Contracts continued on page xii.)

YALE

No Locks are Yale Locks unless made by Yale & Towne.

No new building can be called absolutely modern and up to date unless all the doors are fitted with

The YALE Blount Door Check and Spring

This ingenious contrivance brings a sense of luxury, quietness, and refinement into the home or office which makes one wonder how the old methods of slamming and banging doors could possibly have been tolerated. Doors fitted with the Yale Blount Door Check and Spring can't be left open, can't slam, can't blow open. It holds the door open in any desired position, or closes it automatically at a touch—gradually, gently, but firmly—just the click of the latch is all that you hear.

The Yale Blount Door Check and Spring can be easily fixed up on any kind of door to open from either left or right hand. There are several points about the Yale Blount Door Check and Spring which we would like to explain to you more fully. Will you let us send you a little booklet about it?

BOILER FIXED ON
ANY FLOOR.

MESSRS. BENHAM & SONS, Ltd., have specially designed this system to meet the MODERN and UP-TO-DATE requirements of Architects and Builders.

The system is PERFECT IN ACTION, SIMPLE IN CONSTRUCTION and LOW IN COST, and is specially suitable for buildings where cutting away and making good is an objection to the installation of a heating apparatus.

VERY SMALL SUPPLY PIPES are used and all pipes can be run quite IRRESPECTIVE OF LEVELS. The BOILER CAN BE FIXED ON ANY FLOOR.

ELECTRICAL NOTES.

A New Vacuum Cleaner.

That we have by no means reached finality in vacuum cleaners is obvious to all, but improvements have been rapid during the last year or two. The general criticisms that have been levelled at these machines are that the apparatus are either too heavy to be moved about conveniently or that the light ones of the broom type are not powerful enough and necessitate carrying the dust bag about with the machine. A new type has now been introduced, which seems to have overcome these objections, in that the motor and dust reservoir are stationary, whilst the flexible tube can be moved about, and at the same time the motor and suction are powerful enough to do all that the larger patterns effect in the way of cleaning. The apparatus in question is known as the Wilfisk Vacuum Cleaner, and besides the points enumerated above it has several other advantages.

The dust container and the fan motor are contained in circular stamped steel cases, the latter above the former. The motor runs on an horizontal plane, and the spindle is fitted with two fans in tandem on its lower end, the blades being so arranged that the action of the bottom fan is increased by that of the upper fan, and a very strong pull is thereby achieved. The brush gear and lubrication are accessible by means of inspection covers in the case of the motor, which is also fitted with a switch and flexible wire with plug connection at both ends. The top of the case has a handle, and as the combined case measures 2 ft. high by 12½ in. diameter, and weighs only 35 lb., it can be carried about fairly easily.

The air which passes into the dust con-

tainer is filtered by means of a canvas screen, so as to prevent any dust from penetrating into the motor case. The container is emptied by turning two locking bolts and lifting away the whole of the top containing the working parts. The vacuum can be regulated by adjusting the exhaust parts in the case, and the motor can be cooled, if necessary, during use for lengthy periods by shutting the exhaust parts and opening the inspection covers, so that the air is taken through the motor case. A novel feature of the machine is that it can be employed for blowing as well as for suction, by inserting the flexible tube in one of the exhaust parts. This is useful for many purposes, such as blowing dust out of places which the nozzle cannot reach, airing linen, drying hair, blowing up a fire, etc. The machine includes an outfit of accessories, and is made for all standard voltages. The motor only consumes about 300 watts, say 1-3 of a unit. The Wilfisk cleaner has been put on the market by Gillespie and Beales, Amberley House, Norfolk Street, W.C.

Simplex Heating and Cooking Apparatus.

There will, apparently, be a boom in electric heating and cooking next season. Recent discussions at the Institution of Electrical Engineers have shown what is in the wind, and some papers read last week at the annual convention of Municipal Electrical Engineers at Harrogate have still further emphasised the fact. Manufacturers of these apparatus are busy making preparations, and one of the first to show that they are ready is Messrs. Simplex Conduits, Ltd., who have just issued a new and elaborate catalogue. The principle upon which the heating elements of their apparatus are constructed is high specific resistance wire of special manufac-

ture, wound on thin strips of mica, which are held together in strong but light incorrodible metal sheaths. This wire is not subject to oxidation, and possesses a very low temperature co-efficient. The elements are run at a fairly low temperature, because their construction gives considerable emissive surface per watt of electrical energy, hence they have a long life.

A useful set is the combination cooking outfit, consisting of a 6 in. hot-plate, two-pint aluminium kettle, and aluminium saucepan and frying pan, suitable for a small family. A polished metal oven may be added so as to increase the usefulness of the outfit. The hot-plate is fitted into an aperture at the bottom, and will cook chops and other things of a similar order. Larger hot plates and corresponding ovens will deal with joints. A series of electric boiling plates in 6, 8, and 10 in. sizes, with or without temperature regulation, are a useful novelty at low prices. A range of vessels of polished aluminium is supplied if required with these, to give the best results. Electric towel-dryers are also an innovation. These are in two patterns—hospital pattern, for fixing to floor, with three tiers, and residence pattern, portable. They take 600 watts each. Electric irons are listed in a variety of types and sizes, from 9s. upwards, including the special laundry iron with revolving connector already described in these notes. There are some very handsome designs of heaters in many types and designs, including special connectors for corridors, offices, theatres, etc., as well as hot cupboards and other utensils of all kinds. The attention given to design is very gratifying. It is one more proof that high utility does not necessarily imply a negation of taste. Those interested in the subject should not fail to write for a catalogue.

ELECTRIC LIGHT FITTINGS,

and all kinds of Architectural Metal Work, are made at our well-equipped and modern factory.

We maintain a permanent staff of expert designers and are prepared to submit special drawings to architects' requirements at short notice.

Final EXAMINATION for the R.I.B.A.

The Institute now requires as testimonies of study for the Final Examination at least four designs in answer to their bi-monthly problems. In working out these designs, which are mainly of a monumental character and have to be executed in shaded drawings, the LIVERPOOL SKETCH-BOOK will be found extremely useful. The designs there exhibited include solutions to many similar problems and are all shown in carefully shaded and rendered drawings.

The Journal of the R. I. B. A.:—"The second volume of the Liverpool Annual demands the serious attention of all interested in the development of English Architecture."

Some of the Contents, measured and shaded Drawings, etc. :—

BLenheim PALACE. By Sir John Vanbrugh.
PALais DE JUSTICE, PARIS. By Duc.
ECOLE MILITAIRE, PARIS. By Gabriel.
THE APOTHECARIES HALL, LIVERPOOL.
By Cunningham and Holmes.

THE INLAND REVENUE OFFICES, LIVERPOOL.
TRINITY COLLEGE, DUBLIN.
By Sir William Chambers.
THE BANK OF ENGLAND, LIVERPOOL.
By Cockerell.

The volume also includes schemes for—

A Lofty Office Building.
A Monument to Nelson in St. Paul's Cathedral.
A National Monument at the Approach to a Riverside Town.
A Tomb to a Man of Letters.

A Town House.
A Car Shelter.
A Mausoleum.
A Church Tower.
Compositions of Classical Detail.

The Liverpool Architectural Sketch-Book.

ENLARGED VOLUME.

Price 5/- nett.

6d. extra will be charged for postage (inland) if remittance is not sent with order.

Orders should be sent to the Manager, Technical Journals, Ltd., Caxton House, Westminster, S.W.

Appointments Wanted.

A YOUNG Draughtsman (24) seeks work; well up in interior work, drawings, details, measuring up, etc.—A. J. Wilder, 17, Chester Road, Wanstead, Essex. 7143

Contracts Open.

TO CONTRACTORS.

EAST RIDING OF YORKSHIRE COUNTY COUNCIL.
RECONSTRUCTION OF HULL BRIDGE, NEAR BEVERLEY.

The County Council of the East Riding of Yorkshire are prepared to receive TENDERS for the REMOVAL of the existing BRIDGE across the River Hull, near Beverley, and the CONSTRUCTION of a new OPENING BRIDGE on the site of the existing bridge, together with the CONSTRUCTION and subsequent REMOVAL of a TEMPORARY BRIDGE adjacent thereto. The Contract will include the provision of the machinery for working the bridge, the machinery house, and other continuing works.

The Contract, drawings, and specification may be seen at the Offices or the Engineers, Sir JOHN WOLFE BARRY and PARTNERS, Dartmouth House, 2, Queen Anne's Gate, Westminster, S.W., on and after MONDAY, JUNE 10, between the hours of ELEVEN and FOUR, and copies of the drawings and specification, together with a schedule of quantities and form of Tender, may be obtained there upon payment of ten guineas.

This sum will be repaid by the Council upon receipt of a bona-fide Tender, accompanied by the specification and drawings, which are to be returned with the Tender.

Tenders, endorsed "Tender for Hull Bridge," must be delivered under seal at the office of the CLERK to the EAST RIDING COUNTY COUNCIL, County Hall, Beverley, on or before NOON on FRIDAY, JULY 5.

The lowest Tender will not necessarily be accepted.

JOHN BICKERSTETH,

Clerk of the County Council.

County Hall,
Beverley,

May 23, 1912.

TO BUILDERS AND CONTRACTORS.

TENDERS are INVITED for the following:
(1) LAYING DOWN MAIN ROADS and SEWERS for a housing scheme near Cardiff, comprising in all about 500 houses.

(2) THE ERECTION and COMPLETION of about 500 WORKMEN'S HOUSES, part semi-detached, part in blocks of six.

Builders desirous of tendering for either one or both contracts are asked to communicate immediately with the undersigned, from whom all particulars can be obtained.

W. BEDDOE REES,

Architect.

3, Dumfries Place,

Cardiff.

BOROUGH OF HOVE.

NEW SEWERS.

TENDERS are INVITED for CONSTRUCTING new SEWERS in Queen's Gardens, Grand Avenue, The Drive, Holland Road, and Davigdor Road, within the Borough.

Plans, specification, and form of contract may be seen, and bills of quantities and form of tender obtained, at the Office of the Borough Surveyor, Mr. Hugh Hamilton Scott, on payment of two guineas, which sum will be returned on the receipt of a bona-fide tender.

The lowest or any tender not necessarily accepted.

Tenders, on the forms provided, endorsed "Tender for New Sewers," addressed to the undersigned, will be received up to SIX o'clock on WEDNESDAY, the 3rd JULY next.

Town Hall, Hove.

7th June, 1912.

H. ENDACOTT,

Town Clerk.

TO BUILDERS.

The Commissioners of H.M. Works and Public Buildings are prepared to receive TENDERS for the EXTENSION of BEDFORD POST OFFICE.

Drawings, specification, and a copy of the conditions and form of contract may be seen on application to the POSTMASTER at Bedford Post Office.

Bills of quantities and forms of tenders may be obtained at H.M. OFFICE of WORKS, Storey's Gate, London, S.W., on payment of one guinea. The sums so paid will be returned to those persons who send in tenders in conformity with the conditions specified below.

The Commissioners do not bind themselves to accept the lowest or any tender.

Tenders must be delivered before ELEVEN o'clock a.m. on FRIDAY, the 5th JULY, 1912, addressed to the SECRETARY, H.M. Office of Works, etc., Storey's Gate, London, S.W., and endorsed "Tender for Bedford Post Office Extension."

H.M. Office of Works, etc.

June 11, 1912.

Competitions Open.

TO ARCHITECTS COMPETING.
SCHEMES & ESTIMATES FOR ENGINEERING WORK

(Lighting, Heating, Ventilation, and Sanitation), and Architectural Metal Work, supplied free of charge of STRODE & CO., 48, Osnaburgh Street, London, N.W.

Partnership.

YOUNG ARCHITECT, thoroughly qualified; for five years with leading Domestic Architect, desires partnership, or appointment with view to same in busy Provincial Office.—Box 7150, ARCHITECTS' AND BUILDERS' JOURNAL Office.

Property to Let or For Sale.

By order of Executors.
BEXHILL-ON-SEA.

Eligible Freehold BUILDING LAND, situate in one of the highest and healthiest positions in this charming seaside resort, with frontages to boulevard roads, sewerage and lighted, and commanding good views over the Channel.

Ripe for immediate profitable development.

WEATHERALL AND GREEN will SELL by AUCTION, at the Mart, London, E.C., on Monday, July 8, at 2 o'clock, in one lot, the FREEHOLD BUILDING LAND, having frontages of 450 feet to the Buckhurst Road, and 170 feet to the Upper Sea Road, and containing an area of nearly 3½ acres; situate at an altitude of from 100 to 125 feet above Ordnance datum, and being midway between the L.B. and S.C.Ry. Station and Bexhill Old Town.

Particulars, plan, and conditions of sale may be obtained of Messrs. Phillips and Cheesman, solicitors, 23, Havelock Road, Hastings; and of the Auctioneers, 22, Chancery Lane, London. 7133

To Ironmongers, Builders, Architects, Private Buyers and others.

TECHNICAL JOURNALS' PUBLICATIONS

The Practical Exemplar of Architecture.

Selected by MERVYN E. MACARTNEY, B.A., F.S.A., F.R.I.B.A.

The scheme of the EXEMPLAR is to give an absolute and correct reproduction of fine details from the old and new Masterpieces of Architectural Design and Construction by means of Photographs and Measured Drawings. Each series (issued in a Portfolio) forms a unique collection of ancient and modern work, ready for immediate use and adaptation.

Series I. (1907), 120 Plates and Portfolio	...	15/-	each
Series II. (1909), 112 " 8 pp. descriptive Notes, and Portfolio	...	15/-	Nett,
Series III. (1910), 112 " " " " Annotated	...		post free
Index, and Portfolio	12/6		(Inland).

The Architects' and Builders' Journal.

"THE ARCHITECTS' AND BUILDERS' JOURNAL" is a publication which, while giving due attention to the higher aspects of Architecture, deals particularly with the more practical side of the art. Informative articles, by acknowledged experts, upon all points of construction are standing features of the Journal; and the very latest news of building trade activity is given week by week. All subscribers are entitled to the services of specially retained experts whenever confronted by a difficulty.

"DETAILS, OLD AND NEW," showing measured drawings and photographs of the elevations of noteworthy work, are a regular feature of each weekly issue. This valuable series commenced March 22, 1911.

Every Wednesday, Price 2d. Annual Post Free Subscription, 10/10; Canada, 13/-; elsewhere abroad, 19/6.

The Liverpool Architectural Sketch Book.

Being the Annual of the School of Architecture of the University of Liverpool. The Liverpool Architectural Sketch Book, comprising some 112 illustrations, affords striking evidence of the forward movement in Architectural Education. The drawings are skilfully executed, and have been fully reproduced on heavy art paper, in a handsome 4to volume.

Vol. I. 1910. Price 2/6 nett.

Vol. II. 1911. New and Enlarged Number. Price 5/- nett.

The Volumes will be sent Post Free (Inland) if remittance accompanies the order.

Recent English Domestic Architecture.

Edited by MERVYN E. MACARTNEY, B.A., F.S.A., F.R.I.B.A.

English Domestic Work is of acknowledged supremacy in the domain of Architecture. These Special Issues give a magnificent collection of the work of the best architects of the day, and are of the greatest value, not only to architects and builders, but also to those having estates to develop, and others who are interested in house-building.

1908. Vol. I. Out of print.

1909, 1910. Vols. II. and III. Price 7/6 each nett.

1911. Vol. IV. Price 5/- nett.

The Volumes will be sent Post Free (Inland) if remittance accompanies the order, otherwise postage will be charged.

Practical Notes for Architectural Draughtsmen.

By A. W. S. CROSS, M.A., F.R.I.B.A., AND A. E. MUNBY, M.A., A.R.I.B.A.

Gives in most convenient form for use on the drawing-board examples with concise rules, explanations, and dimensions for preparing Designs, Perspectives, and Working Drawings for Classical Architecture with rapidity and precision. It contains a mass of valuable information with carefully drawn examples. How to draw "The Orders" correctly with the smallest possible amount of study and work is shown by the invaluable drawings and data given in this publication.

Price 15/- nett, Post Free (Inland), including Portfolio.

Specification :

FOR ARCHITECTS, SURVEYORS, AND ENGINEERS, WHEN SPECIFYING. Among the Important Special Contributions appearing in this Volume are the following :—Cinematograph Theatres, Notes on Motor Garages, Glossary of Technical Terms, Half-Timber Construction, Methods of Illumination (Acetylene Gas, Coal Gas, Oil, Petrol Gas, etc.), Working Drawings of some Important Recent Buildings. The work is the "Standard Encyclopædia of Technical Information" on all subjects which arise when specifications are being prepared.

No. 14, 1911-12. Price 3/6 nett, postage (Inland) 6d. extra.
Over 500 pages, 13 in. by 9 in., strongly bound.

Orders should be sent to The Manager, TECHNICAL JOURNALS, Ltd.,
Caxton House, Westminster, S.W.

THE SECOND EDITION OF English Ecclesiastical Architecture

13 in. x 8¾ in., bound full cloth. 250 pages.

Ecclesiastical Architecture, more especially Gothic, offers many pitfalls to the designer. In the old work there is a subtle quality which is very difficult to achieve in church buildings of the present day. It demands from the architect not only a thorough knowledge of the constructional fitness which is the basis of Gothic, but also a keen sense of proportion, and a fertility of invention in the design of detail.

English Ecclesiastical Architecture, like English Domestic Architecture, has great traditions, and it is fortunate that there should exist a school of men among English architects who possess the ability to produce work of the highest character. The ecclesiastical buildings of the prominent exponents of the Gothic Revival—Pugin, Scott, Butterfield, and the rest—have already been fully illustrated, but never before has there been brought together a representative series of photographs of the recent work of English church architects. The value of this present collection therefore is self-evident. Examples of the best modern church work are included, and the volume is fully representative of what is being done by the chief architects of the present day, including buildings of Renaissance character as well as Gothic. The illustrations are from specially-taken photographs reproduced to a large size.

PRICE 10/6 nett.
